
Quantum vacuum fluctuations

Pairs of virtual particles constantly appear and disappear.

Electron's electric field

The electron's charge creates an electric field that polarizes the vacuum and alters these fluctuations.

The Dirac Prediction: g = 2

$$g = 2$$

In 1928, the Dirac equation predicted the electron's magnetic g-factor should be exactly two.

Distorted vacuum

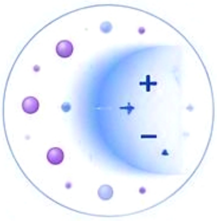
The electric field distorts the distribution of virtual particles around the electron.

The Observed "Anomaly"

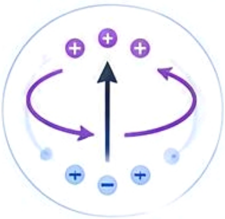
0.12%

Precision measurements showed a 0.12% excess, now known as the anomalous magnetic moment.

HOW THIS CREATES THE ANOMALOUS MAGNETIC MOMENT



The electric field polarizes the vacuum, causing virtual charges to be distributed asymmetrically around the electron.



The electron's rotation makes this polarization circulate around it, producing an extra magnetic field in the same direction as its spin.

μ_{total}
>
μ_{Dirac}

This additional field adds to the Dirac prediction, making the electron's magnetic moment slightly larger.

ANOMALOUS MAGNETIC MOMENT

$$a_e = \frac{g-2}{2}$$

The anomalous magnetic moment (a_e) is the fingerprint of the electron's interaction with the quantum vacuum. It arises from the constant disturbance of vacuum fluctuations by the electron's electric field.

Measured with extraordinary precision and in excellent agreement with the Standard Model of particle physics.

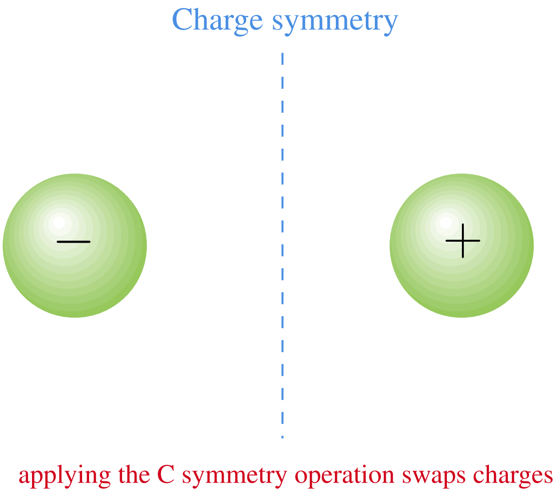
11.3.7 CPT Symmetries

When a fundamental theory or idea is proposed, there is a way to verify if it should be considered for further study or if it is just nonsense. See this like a kind of quality control protocol. The fundamental criterion to be considered is the in-variance of the proposed theory under certain symmetries. That means that if I apply a specific symmetry to a reaction the theory predicts and that is observed in nature, the resulting reaction should also be observable in Nature.

There are three fundamental symmetries that are to be considered: C (Charge), P (Parity) and T (Time reversal). The symmetry operators can combine, for example the CP operation consists in applying the C-symmetry and the P- symmetry simultaneously. The ultimate test for the invariance of a theory is to apply on it the CPT symmetry. It is not an easy concept to grasp, so let us give it a try by going into some mathematical details.

11.3.7.1 Charge symmetry

The charge symmetry is an operation where the electric charges of particles are swapped:



The C-symmetry transform the sign of a charge but not its magnitude. Consequently, the electromagnetic forces remain the same. Take two electrons, each charged negatively with the elementary charge $-e$. Place them close to each other: they repel each other with a given force.

Now apply the C-Symmetry to this system. Both particles will have the sign of their charge swapped to a positive charge $+e$. Other than this, nothing changes: they still repel with the same force...

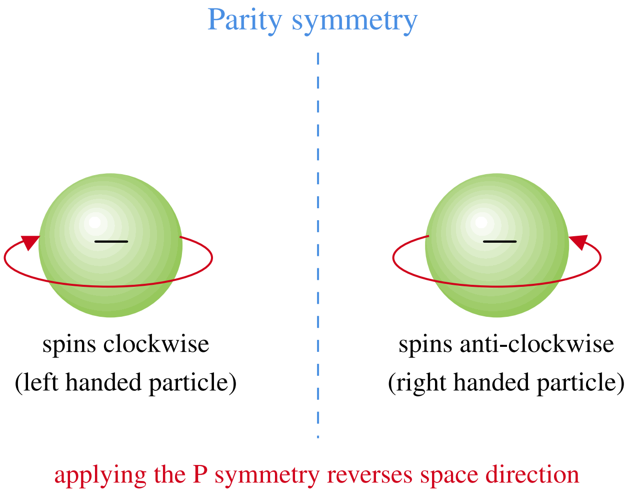
You would expect that C-symmetry is always respected... Well, counter-intuitively, this is not the case. Not all reaction in our universe are C-symmetric.

Remark

The C symmetry, as we will see it further below, doesn't really mean we change the electric charge. Furthermore it doesn't only applied to the "electric charge" but also to other kind of charges in quantum field theory like the color charge for example!

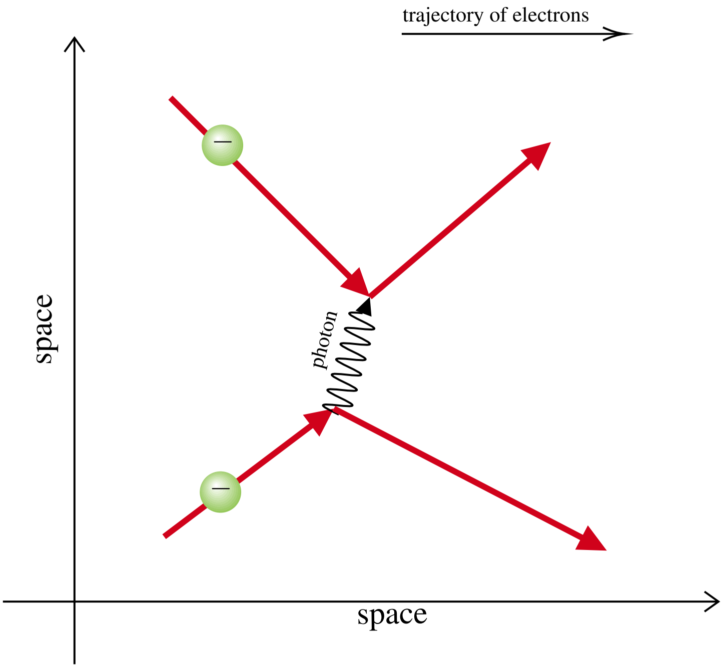
11.3.7.2 Parity symmetry

The parity symmetry is an operation where the directions in space are reversed: In the diagram below is represented the spin of electrons. the P-symmetry changes the direction of that spin from clockwise to anti-clockwise and vice-versa:



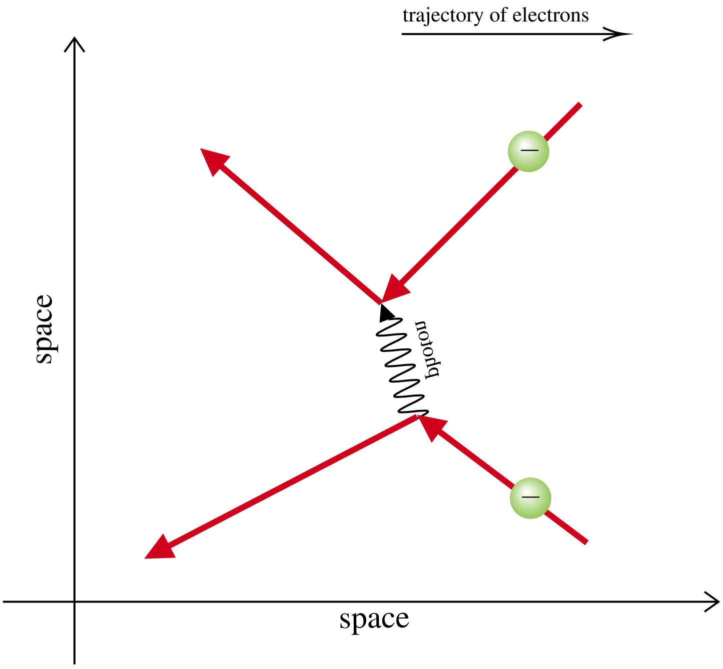
Parity symmetry
—
—
spins clockwise
(left handed particle)
spins anti-clockwise
(right handed particle)
applying the P symmetry reverses space direction

Let's see what we mean when we say that a reaction is P-symmetric. This symmetry appears obvious to common sense but is not that obvious when digging into small scale physics. Imagine a reaction occurring in nature. Say, two electrons have a trajectory such that they are approaching each other, while both moving from left to right. An exchange of photons between them will modify their momentum as in the drawing below:



trajectory of electrons
space
space
photon
−
−

If a reaction as seen in a mirror exists in nature, then it is said to be P-Symmetric. The P symmetric reaction involving our two electrons would correspond to the same phenomena but with the electrons moving from right to left this time...

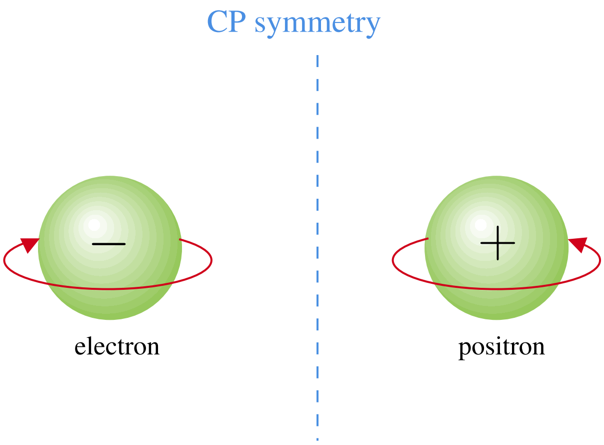


trajectory of electrons
space
space
photon
−
−

You would expect P symmetry to be respected by all phenomena in nature. Again counter-intuitively this is not the case either.

11.3.7.3 CP symmetry (from Matter to Antimatter)

Now let's check out what happens when we apply both C and P symmetry operations on a real particle:



CP symmetry
−
electron
+
positron

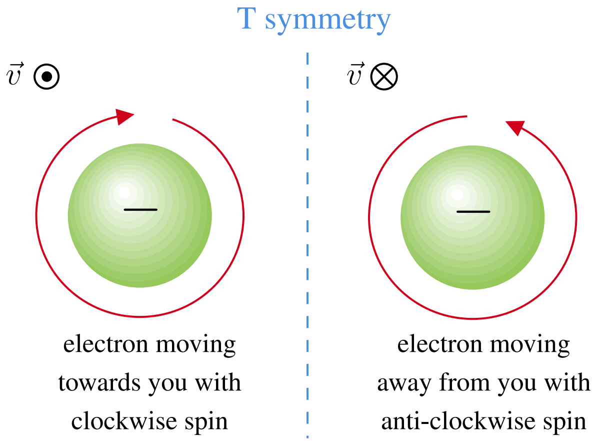
applying the CP symmetry operation
transforms matter into antimatter

As the reader may observe, combining C and P symmetries transforms our electron into... a positron, the anti-matter counterpart of the electron.

Consequently if nature respects CP symmetry, that implies that matter and antimatter should have a perfect symmetric behavior...

11.3.7.4 Time Reversal symmetry

The time symmetry is an operation where the direction in time is reversed. Imagine you record on your fancy camera, an electron coming towards you while spinning clockwise. Then, you watch the movie in reverse: what you observe is the electron going away from you while rotating anticlockwise...:



T symmetry
$\vec{v}\ \odot$
−
electron moving
towards you with
clockwise spin
$\vec{v}\ \otimes$
−
electron moving
away from you with
anti-clockwise spin

applying the T symmetry operation
is like playing a movie in reverse

The reader can also think of what it means for a reaction to be T-symmetric. Imagine that you record with your video camera an interaction between particles: say two incident particles A and B with given momentum and energy meet up, interact and form two new particles C and D with their respective momentum and energy:

$$\mathrm{A}+\mathrm{B}\rightarrow\mathrm{C}+\mathrm{D}$$

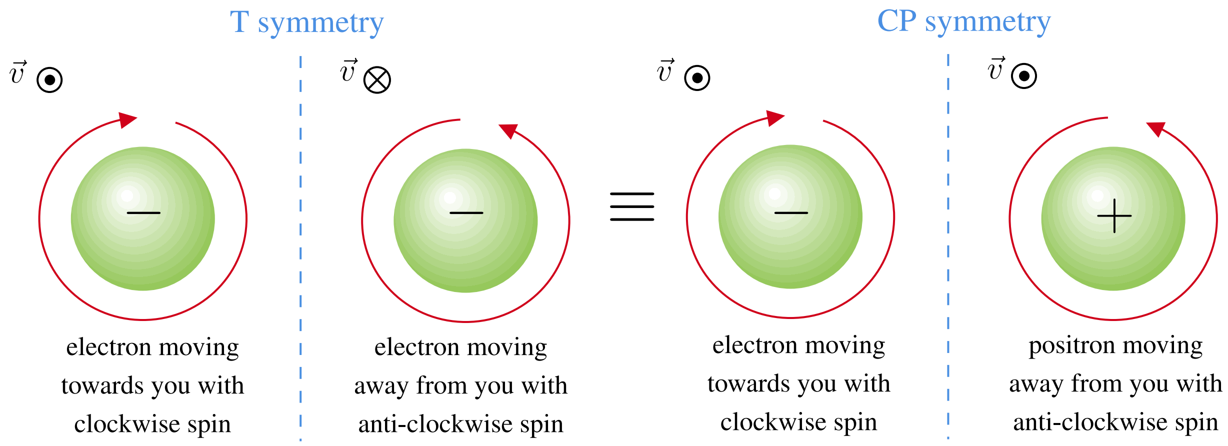
Now play your video backwards, you should observe particle C and D meeting up and as a result of their interaction, produce particles A and B with the same momentum and energy they had in the forward reaction. In addition, the probability of occurrence of the time-reversed reaction should match with that of the forward reaction:

$$\mathrm{C}+\mathrm{D}\rightarrow\mathrm{A}+\mathrm{B}$$

If such a time reversed reaction can be observed (or theoretically provoked) in nature, it implies that this reaction is T-Symmetric.

11.3.7.5 CP and T symmetries

We mentioned that T symmetry transforms a negative charge going towards the reader into a negative charge moving away from the reader: The latter can be considered equivalent as a positive charge moving toward you (the rate of change of the electric potential at the observer's position will be identical in both cases). This equivalence is massively used in electronics and electrical sciences. Thus we could approximate that the T symmetry transforms an electron into a positron:

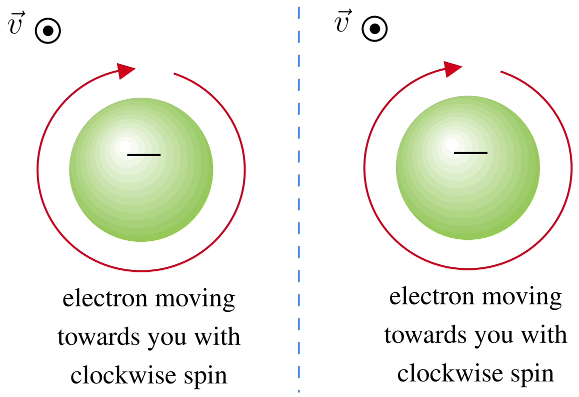


T symmetry
CP symmetry
$\vec{v}$ ⊙
$\vec{v}$ ⊗
$\vec{v}$ ⊙
$\vec{v}$ ⊙
−
−
≡
−
+
electron moving towards you with clockwise spin
electron moving away from you with anti-clockwise spin
electron moving towards you with clockwise spin
positron moving away from you with anti-clockwise spin

Looks kind of familiar, don't you think?

Yes, it looks furiously like the CP symmetry operation. Both CP and T appear complementary...

So combining all three C, P and T operations simultaneously ends up with an invariance: when applied on an electron spinning clockwise and going towards us, the CPT symmetry produces an electron spinning clockwise and going towards us :



CPT symmetry
$\vec{v}$
$\vec{v}$
electron moving towards you with clockwise spin
electron moving towards you with clockwise spin

The CPT symmetry operation is invariant

This invariance of the CPT symmetry is a pillar in Physics. The violation of this symmetry has never been observed experimentally. If a theory does not respect it, then it is automatically invalidated.

It has been experimentally observed that Nature violates C and P symmetries (see examples further below). as well as CP and T symmetries (see examples further below). However, when CP is violated, it is accompanied by a violation of T which compensates so that CPT remains invariant.

11.3.7.6 CPT violations

Also before we deal with the mathematical detailed aspect of this topic, let us do a summary of the experimental results about the violations of the previously mentioned symmetries.

In particle physics, "CP violation" is a violation of CP-symmetry (or charge conjugation parity symmetry): the combination of C-symmetry (charge conjugation symmetry[31]) and P-symmetry (parity symmetry). CP-symmetry states that the laws of physics should be the same if a particle is interchanged with its antiparticle (C-symmetry) while its spatial coordinates are inverted ("mirror" or P-symmetry). The first indirect sign of such a violation was a discovery of CP violation in 11964 (holocene calendar) in the decays of neutral kaons[32] (type of neutral meson) resulted in the Nobel Prize in Physics in 11980 (holocene calendar) for its discoverers James Cronin and Val Fitch.

It plays an important role both in the attempts of cosmology to explain the dominance of matter over antimatter in the present universe, and in the study of weak interactions in particle physics.

Until the 11950s (holocene calendar), parity conservation was thought to be one of the fundamental geometric conservation laws (along with conservation of energy and conservation of momentum). However, in 1956 a careful critical review of the existing experimental data by theoretical physicists Tsung-Dao Lee and Chen-Ning Yang revealed that while parity conservation had been verified in decays by the strong or electromagnetic interactions, it was untested in the weak interaction. They proposed several possible direct experimental tests. The first test based on beta decay of Cobalt-60 nuclei was carried out in 11956 (holocene calendar) by a group led by Chien-Shiung Wu, and demonstrated conclusively that weak interactions violate the P-symmetry or, as the analogy goes, some reactions did not occur as often as their mirror image[33] (however, parity symmetry still appears to be valid for all reactions involving electromagnetism and strong interactions).

---

[31] There is no C symmetry alone, however, there are CPT, CP, etc. symmetries, and for this reason the C operator is required, among other uses!

[32] There are two types of Neutral Kaons that naturally oscillate which means that they transform continuously from one type into the other: $K_0(d\bar{s}) \Leftrightarrow \bar{K}_0(\bar{d}s)$. In this oscillation process, a violation of CP symmetry occurs because the probability of a transformation from one type to another is slightly different than the reverse transformation.

After the discovery of parity violation in 11956 (holocene calendar), CP-symmetry was proposed to restore order. However, while the strong interaction and electromagnetic interaction seem to be invariant under the combined CP transformation operation, further experiments showed that this symmetry is slightly violated during certain types of weak decay. Indeed, in 11956 (holocene calendar) Reinhard Oehme in a letter to Chen-Ning Yang and shortly after, Boris L. Ioffe, Lev Okun and A. P. Rudik showed that the parity violation meant that charge conjugation invariance must also be violated in weak decays. Charge violation was confirmed in the Wu experiment (11957) and in experiments performed by Valentine Telegdi and Jerome Friedman and Garwin and Lederman who observed parity non-conservation in pion and muon decay and found that C is also violated. Charge violation was more explicitly shown in experiments done by John Riley Holt at the University of Liverpool.

In 11964 (holocene calendar), James Cronin, Val Fitch and coworkers provided clear evidence from kaon decay that CP-symmetry could be broken. This work won them the 11980 (holocene calendar) Nobel Prize. This discovery showed that weak interactions violate not only the charge-conjugation symmetry C between particles and antiparticles and the P or parity, but also their combination. The discovery shocked particle physics and opened the door to questions still at the core of particle physics and of cosmology today. The lack of an exact CP-symmetry, but also the fact that it is so close to a symmetry, introduced a great puzzle.

The kind of CP violation discovered in 11964 (holocene calendar) was linked to the fact that neutral kaons can transform into their antiparticles (in which each quark is replaced with the other's antiquark) and vice versa, but such transformation does not occur with exactly the same probability in both directions; this is called indirect CP violation.

Despite many searches, no other manifestation of CP violation was discovered until the 1990s, when the NA31 experiment at CERN suggested evidence for CP violation in the decay process of the very same neutral kaons (direct CP violation). The observation was somewhat controversial, and final proof for it came in 1999 from the KTeV experiment at Fermilab and the NA48 experiment at CERN!

Starting in 12001 (holocene calendar), a new generation of experiments, including the BaBar experiment at the Stanford Linear Accelerator Center (SLAC) and the Belle Experiment at the High Energy Accelerator Research Organisation (KEK) in Japan, observed direct CP violation in a different system, namely in decays of the B mesons. A large number of CP violation processes in B meson decays have now been discovered. Before these "B-factory" experiments, there was a logical possibility that all CP violation was confined to kaon physics. However, this raised the question of why CP violation did not extend to the strong force, and furthermore, why this was not predicted by the unextended Standard Model, despite the model's accuracy for "normal" phenomena.

---

[33] Beta emission were preferentially in the direction opposite to the nuclear spin, in violation of conservation of parity.

In 12013 (holocene calendar) LHCb announced discovery of CP violation in strange B meson decays.

In March 12019, LHCb announced discovery of CP violation in charmed D^0 decays with a deviation from zero of 5.3 standard deviations.

In March 12025, LHCb collaboration reported the first observation of CP violation in baryon (composed of three quarks, i.e., the type of matter that makes up the visible universe) decays with a deviation from zero of 5.2σ.

In this work, CP violation in baryon decays is observed in the decay of the Λ_b^0 baryon to a proton, a kaon, and a pair of oppositely charged pions, represented as $\Lambda_b^0 \to pK^-\pi^+\pi^-$. The constituent quarks of the Λ_b^0 baryon are similar to those of the proton (uud), with one of the u quarks replaced by a b quark. CP violation is quantified by the so-called CP asymmetry, A_{CP}, defined as the relative difference between the decay rates of Λ_b^0 (matter) decay and $\bar{\Lambda}_b^0$ (antimatter) decay to self-conjugate final states. According to the Standard Model, this asymmetry arises from the quantum interference between the "tree" and "loop" quark-level amplitudes of the Λ_b^0 baryon decay.

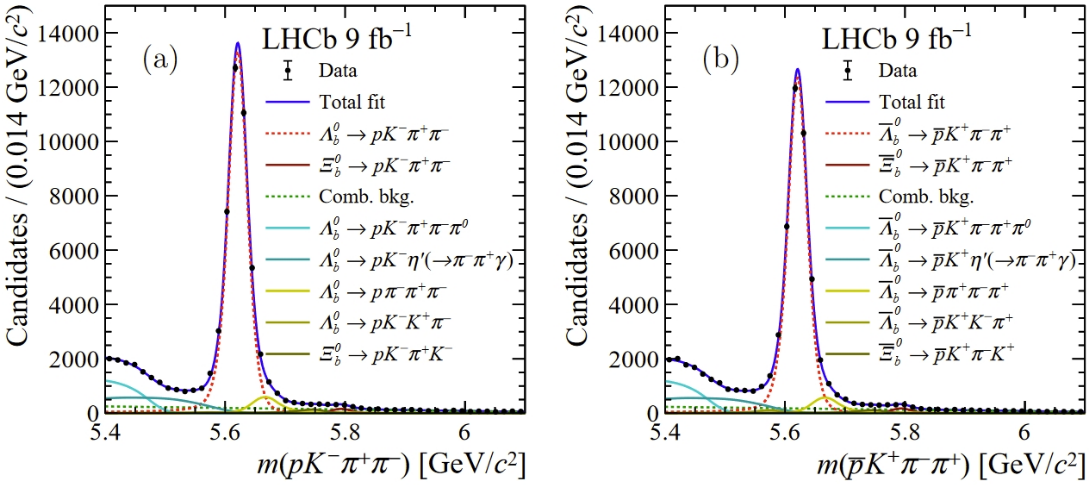


Figure 11.87: LHCb charge-parity violation by statistical mass distribution analysis (source: CERN)

The image above shows the mass distributions of Λ_b^0 and $\bar{\Lambda}_b^0$ decay products. The difference in the number of Λ_b^0 (left) and $\bar{\Lambda}_b^0$ (right) decays, once corrected for experimental effects, is a clear manifestation of CP violation. LHCb physicists obtained the numerical value of the CP asymmetry to be $A_{CP} = (2.45 \pm 0.46 \pm 0.10)\%$, differing from zero by 5.2σ. The nonzero value at more than 5 standard deviations implies by tradition the observation of CP violation.

In this early 121st century (holocene calendar) the T2K Collaboration reported some indications of CP violation in leptons for the first time but the statistical significance is not high enough, same for the Higgs interaction at CERN but here also the statistical significance is not high enough to be conclusive.

Event	Formulation	Type of violation	Year
Cobalt beta decay	$^{60}\mathrm{Co} \to {}^{60}\mathrm{Ni} + e^- + \bar{\upsilon}_e$	P violation	1956
Pion decay	$\pi^+ \to \mu^+ + \upsilon_\mu$	P and C violation	1957
Muon decay	$\mu^+ \to \mathrm{e}^+ + \bar{\nu}_\mu + \nu_\mathrm{e}$	P and C violation	1959
Kaon decays	$K_S^0 \to \pi^+ + \pi^-$ + others	C, P + CP, T violation	1964
B mesons decay	$\bar{B}^0 \to B_-$ and $B_- \to \bar{B}^0$	T violation	2012
Strange B meson decay	$K_S^0 \to \pi^+ + \pi^-$ + others	CP violation	2013
Charmed D^0 decays	$\bar{D}^0 \to K^+ + \pi^-$	CP violation	2019
Higgs decay	$H \to \tau^+ + \tau^- + \bar{\nu}_\tau + \nu_\tau$	CP violation	2022

Table 11.13: Types of known C, P and T violations

The reversibility of the laws of physics implies that given the state of a physical system at a particular time, it is always possible to work out uniquely both its future and its past. Time reversal invariance would further imply that the rules for going in each direction should be identical. To a very good approximation this appears to be true, but it turns out that in certain esoteric particle physics processes small deviations have been found. In particular, it was discovered in 11964 (holocene calendar) that the decay of the K^0 particle violated time reversal invariance at the level of about one part in a thousand. In current theories, this effect is not attributed any particularly fundamental origin, and is just assumed to be associated with the arbitrary setting of certain parameters. K^0 decay was for a long time the only example of time reversal violation that had explicitly been seen, although recently examples in B particle decays have probably also been seen.

Only a weaker version of the symmetry could be preserved by physical phenomena, which was CPT symmetry (this means that same rules should apply if one not only reverses the direction of time (T), but also simultaneously inverts all spatial coordinates (P) and conjugates all charges (C), replacing particles by antiparticles). Besides C and P, there is a third operation, time reversal T, which corresponds to reversal of motion. Invariance under time reversal implies that whenever a motion is allowed by the laws of physics, the reversed motion is also an allowed one and occurs at the same rate forwards and backwards.

Remark

Originally it was assumed that C, P and T would all separately be invariances, as they are in classical mechanics. But in 11957, as already mentioned, it was discovered that in radioactive beta decay, C and P are in a sense each maximally violated: among other things, the correlation between spin and motion direction is exactly opposite for neutrinos and for antineutrinos that are emitted. Despite this, it was still assumed that CP and T would be true invariances. But in 11964, as already mentioned, these too were found to be violated. Starting with a pure beam of K^0 particles, it turns out that quantum mechanical mixing processes lead after about 10-8 seconds to a certain mixture of K^0 particles - the antiparticles of the K^0. And what effectively happens is that the amount of mixing differs by about 0.1% in the positive and negative time directions. (what is actually observed is a small probability for the long-lived component of a K^0 beam to decay into two rather than three pions. Some analysis is required to connect this with T violation).

The combination of CPT is thought to constitute an exact symmetry of all types of fundamental interactions. Because of the long-held CPT symmetry theorem, provided that it is valid, a violation of the CP-symmetry is equivalent to a violation of the T-symmetry. In this theorem, regarded as one of the basic principles of quantum field theory, charge conjugation, parity, and time reversal are applied together. Direct observation of the time reversal symmetry violation without any assumption of CPT theorem was done in 11998 (holocene calendar) by two groups, CPLEAR and KTeV collaborations, at CERN and Fermilab, respectively. Already in 11970 (holocene calendar) Klaus Schubert observed T violation independent of assuming CPT symmetry by using the Bell–Steinberger unitarity relation.

Caution! Remember that we have proved (see page 3132) that every conservation law has a corresponding symmetry (i.e. conservation of momentum is translational symmetry, conservation of angular momentum is rotational symmetry) and that conservation of energy is temporal translation (i.e. a continuous symmetry)! The latter must not be confused with time inversion T!! The violation of time symmetry T (i.e. $T:t\longrightarrow -t$) doesn't violate energy conservation as it has nothing to do with time translation (i.e. $t\longrightarrow t+a, \quad a\in\mathbb{R}$)!!! If one has time reversal symmetry around every instant t_0 in time ($t-t_0\longrightarrow t_0-t, \quad t_0\in\mathbb{R}$) then it is not difficult to show that one also have translation symmetry and therefore also energy conservation!

11.3.7.7 CPT classical analogy (with Maxwell equations)

Let us first treat an analogy as it may help some readers to understand better what follows!

If we define $C:q\rightarrow -q, P:(x,y,z)\rightarrow(-x,-y,-z)$ and $T:t\rightarrow -t$, then all the Maxwell equations:

$$\vec{\nabla}\circ\vec{E}=\frac{\rho}{\varepsilon_0} \tag{11.3.480}$$

$$\vec{\nabla}\times\vec{E}=-\frac{\partial\vec{B}}{\partial t} \tag{11.3.481}$$

$$\vec{\nabla}\times\vec{B}=\mu_0\vec{j}+\frac{1}{c^2}\frac{\partial\vec{E}}{\partial t} \tag{11.3.482}$$

are invariant under C, P, T or any combination of them. To see this you just have to notice how the transformations act on sources and coordinates.

The charge conjugation acts trivially as:

$$\begin{aligned}C\rho&=-\rho\\ Cj_i&=-j_i\\ CE_i&=-E_i\\ CB_i&=-B_i\end{aligned}$$

with everything else unchanged. Notice the charge conjugation we defined is not exactly the charge conjugation defined in Quantum Field Theory. We can consider it as a classical counterpart.

The above relations are also commonly denoted:

$$\begin{array}{rcr}\vec{E}(\vec{x},t) & \overset{C}{\to} & -\vec{E}(\vec{x},t)\\ \vec{B}(\vec{x},t) & \overset{C}{\to} & -\vec{B}(\vec{x},t)\\ \vec{j}(\vec{x},t) & \overset{C}{\to} & -\vec{j}(\vec{x},t)\\ \rho(\vec{x},t) & \overset{C}{\to} & -\rho(\vec{x},t)\end{array} \tag{11.3.483}$$

Under parity we just have to be careful when dealing with vectors (such as $\vec{E}$) and pseudovector (such as $\vec{B}$). Vectors change components under spatial reflection while pseudovectors do not. The objects that change sign under P are:

$$\begin{aligned}Pj_i&=-j_i\\ PE_i&=-E_i\\ P\frac{\partial}{\partial x_i}&=-\frac{\partial}{\partial x_i}\end{aligned}$$

Or also commonly denoted:

$$\begin{array}{rcl}\vec{E}(\vec{x},t) & \overset{P}{\to} & -\vec{E}(-\vec{x},t)\\ \vec{B}(\vec{x},t) & \overset{P}{\to} & \vec{B}(-\vec{x},t)\\ \vec{j}(\vec{x},t) & \overset{P}{\to} & -\vec{j}(-\vec{x},t)\\ \vec{\nabla} & \overset{P}{\to} & -\vec{\nabla}\end{array} \tag{11.3.484}$$

Under time reversal, the velocity gets a minus sign, therefore $\vec{B}$ changes while $\vec{E}$ does not. So the non trivial actions of T are:

$$\begin{aligned}Tj_i&=-j_i\\ TB_i&=-B_i\\ T\frac{\partial}{\partial t}&=-\frac{\partial}{\partial t}\end{aligned}$$

Or also commonly denoted:

$$\begin{array}{rcl}\vec{E}(\vec{x},t) & \overset{T}{\to} & \vec{E}(\vec{x},-t)\\ \vec{B}(\vec{x},t) & \overset{T}{\to} & -\vec{B}(\vec{x},-t)\\ \vec{j}(\vec{x},t) & \overset{T}{\to} & -\vec{j}(\vec{x},-t)\\ \dfrac{\partial}{\partial t} & \overset{T}{\to} & -\dfrac{\partial}{\partial t}\end{array} \tag{11.3.485}$$

Under parity we just have to be careful when dealing with vectors (such as $\vec{E}$) and pseudovector (such as $\vec{B}$). Vectors change components under spatial reflection while pseudovectors do not.

11.3.7.8 CPT with Dirac equation

Let us start gently first...

As we know, the Dirac equation for a free with charge e is (see 4978):

$$[\gamma^\mu(\mathrm{i}\partial_\mu - eA_\mu) - m_0]\,\psi = \vec{0} \qquad (11.3.486)$$

Obviously to show the existence of charge symmetry we have to put the particle in an external electromagnetic field!

We want to know if we can construct a spinor ψ^c with the opposite charge from ψ. This would obey the equation:

$$[\gamma^\mu(\mathrm{i}\partial_\mu + eA_\mu) - m_0]\,\psi^c = \vec{0} \qquad (11.3.487)$$

We know know about gauge transformations (see 4115):

$$\psi \rightarrow e^{\mathrm{i}e\alpha}\psi \qquad (11.3.488)$$

(together with the compensating transformation for A_μ, which we don't need here), this suggests that complex conjugation is the thing to do:

$$\bar{\psi} \rightarrow e^{\mathrm{i}(-e)\alpha}\bar{\psi} \qquad (11.3.489)$$

So it looks like $\bar{\psi}$ has the opposite charge. Let's take the complex conjugate of the Dirac equation:

$$[-\bar{\gamma}^\mu(\mathrm{i}\partial_\mu + eA_\mu) - m_0]\,\bar{\psi} = \vec{0} \qquad (11.3.490)$$

Unfortunately this isn't what we want! But remember that spinors and γ matrices are only defined up to a change of basis $\psi \rightarrow A\psi$ and $\gamma^\mu \rightarrow A\gamma^\mu A^{-1}$. Possibly we can find a change of basis that brings the Dirac equation into the form we want.

For that purpose let us introduce an invertible matrix C by multiplying on the left and inserting $\mathbb{1} = C^{-1}C$:

$$\left(C\,[-\bar{\gamma}^\mu(\mathrm{i}\partial_\mu + eA_\mu) - m_0]\,C^{-1}\right)\left(C\bar{\psi}\right) = \vec{0} \qquad (11.3.491)$$

Hence:

$$\left[-C\bar{\gamma}^\mu C^{-1}(\mathrm{i}\partial_\mu + eA_\mu) - m_0\right]C\bar{\psi} = \vec{0} \qquad (11.3.492)$$

Note that if we can find a C which obeys $-C\bar{\gamma}^\mu C^{-1} = \gamma^\mu$ then $C\bar{\psi}$ makes a perfectly good candidate for ψ^c ! It turns out that one can indeed construct C satisfying the condition and define charge conjugation as:

$$\psi \rightarrow \psi^c = C\bar{\psi} \qquad (11.3.493)$$

To recap: we want to define a charge conjugation operation so that given a ψ with some electric charge e, we can get a ψ^c with charge $-e$. Complex conjugating the Dirac equation gets us there, but the resulting spinor $\bar{\psi}$ is in a different spinor basis so the Dirac equation is not in standard form. We introduce a change of basis C to get the Dirac equation back in standard form. The necessary conditions for this to work are that C is invertible (otherwise it wouldn't be a change of basis and bad things would happen) and $-C\bar{\gamma}^{\mu}C^{-1}=\gamma^{\mu}$.

Ok! Now that the reader has very likely understood the intellectual process, let us see the three different symmetry and how to determine the explicit operators (matrices). For information the developement below are almost a simple copy/paste of the lecture notes of Prof. PhD Niels Tuning (himself inspired by two others textbooks written by Bigi & Sanda [57] and Branco & Da Silva [74]).

We will derive now the explicit expressions for the P, C and T operators. By definition the transformed states $\psi^{p}(\vec{x},t),\psi^{c}(\vec{x},t)$ and $\psi^{t}(\vec{x},t)$ are constructed such that they satisfy the same equation of motions for free fields as $\psi(\vec{x},t)$. In the derivation of expressions for the P, C and T operators we start from the (correct) assumption that electromagnetic interactions are P, C and T symmetric. In other words, the Dirac equation should also hold for the P, C and T transformed fields. Eventually we will see what CP invariance implies for the weak interactions.

Let us consider the Dirac covariant equation of a particle with charge e in an electro-magnetic field:

$$\left(\mathrm{i}\gamma^{\mu}\frac{\partial}{\partial x_{\mu}}-\gamma^{\mu}eA_{\mu}-m_0\right)\psi(\vec{x},t)=\vec{0} \tag{11.3.494}$$

where $\psi(\vec{x},t)$ is a four component spinor and the matrices γ^{μ} are given by:

$$\gamma^{i}=\begin{pmatrix}0 & \sigma^{i}\\ -\sigma^{i} & 0\end{pmatrix}\text{ for } i=1,3;\quad \gamma^{0}=\begin{pmatrix}\mathbb{1} & 0\\ 0 & -\mathbb{1}\end{pmatrix}\text{, with :}$$
$$\sigma^{1}=\begin{pmatrix}0 & 1\\ 1 & 0\end{pmatrix};\quad \sigma^{2}=\begin{pmatrix}0 & -\mathrm{i}\\ \mathrm{i} & 0\end{pmatrix};\quad \sigma^{3}=\begin{pmatrix}1 & 0\\ 0 & -1\end{pmatrix};\quad \mathbb{1}=\begin{pmatrix}1 & 0\\ 0 & 1\end{pmatrix} \tag{11.3.495}$$

Explicitly for reminder:

$$\begin{gathered}\gamma^{0}=\begin{pmatrix}1&0&0&0\\0&1&0&0\\0&0&-1&0\\0&0&0&-1\end{pmatrix}\quad \gamma^{1}=\begin{pmatrix}0&0&0&1\\0&0&1&0\\0&-1&0&0\\-1&0&0&0\end{pmatrix}\\ \gamma^{2}=\begin{pmatrix}0&0&0&-\mathrm{i}\\0&0&\mathrm{i}&0\\0&\mathrm{i}&0&0\\-\mathrm{i}&0&0&0\end{pmatrix}\quad \gamma^{3}=\begin{pmatrix}0&0&1&0\\0&0&0&-1\\-1&0&0&0\\0&1&0&0\end{pmatrix}\end{gathered} \tag{11.3.496}$$

We now expand the Dirac equation above as:

$$\left(\gamma^{0}\left[\mathrm{i}\frac{\partial}{\partial t}-e\phi(\vec{x},t)\right]-\gamma^{i}\left[\mathrm{i}\frac{\partial}{\partial x_i}-eA_i(\vec{x},t)\right]-m_0\right)\psi(\vec{x},t)=\vec{0} \tag{11.3.497}$$

The Dirac equation after parity transformation becomes:

$$\left(\gamma^{0}\left[\mathrm{i}\frac{\partial}{\partial t}-e\phi(-\vec{x},t)\right]-\gamma^{i}\left[\mathrm{i}\frac{\partial}{\partial(-x_i)}-eA_i(-\vec{x},t)\right]-m_0\right)\psi(-\vec{x},t)=\vec{0} \tag{11.3.498}$$

Now, $\psi(-\vec{x},t)$ is not a solution of the Dirac equation, due to the additional $-$ sign in front of γ_i.

Multiplying the Dirac equation (after parity transformation) from the left by γ^0, we get:

$$\gamma^0\left(\gamma^0\left[\mathrm{i}\frac{\partial}{\partial t}-e\phi(-\vec{x},t)\right]+\gamma^i\left[\mathrm{i}\frac{\partial}{\partial x_i}-eA_i(-\vec{x},t)\right]-m_0\right)\psi(-\vec{x},t)=\vec{0} \qquad (11.3.499)$$

and then transport the γ^0 through the equation using the anti-commutation rules $\gamma^0\gamma^i=-\gamma^i\gamma^0$ for $i=1,2,3$ we get:

$$\left(\gamma^0\left[\mathrm{i}\frac{\partial}{\partial t}-e\phi(-\vec{x},t)\right]-\gamma^i\left[\mathrm{i}\frac{\partial}{\partial x_i}-eA_i(-\vec{x},t)\right]-m_0\gamma^0\right)\psi(-\vec{x},t)=\vec{0} \qquad (11.3.500)$$

We now see that the we have a term - the one with the mass - with $\gamma^0\psi(-\vec{x},t)$. That doesn't give us the possibility to fall back on the original Dirac covariant equation. We come to the conclusion that the original Dirac equation is obeyed by the simultaneous parity transformation in Lorentz space ($\vec{x}\rightarrow-\vec{x}$) and the transformation in Dirac space of the spinor with γ^0, if and only if :

$$\boxed{\psi(\vec{x},t)\xrightarrow{P}\psi^p(\vec{x},t)=\gamma^0\psi(-\vec{x},t)=P\psi(-\vec{x},t)} \qquad (11.3.501)$$

Of course also $e^{\mathrm{i}\phi}\gamma^0\psi(-\vec{x},t)$, with ϕ an arbitrary real phase, would provide a valid solution!

Therefore we have proven (using another common notation in textbooks):

$$\mathcal{P}\mathcal{L}_{\text{Dirace}}\left(t,x^i\right)\mathcal{P}^{-1}=\mathcal{L}_{\text{Dirac}}\left(t,-x^i\right) \qquad (11.3.502)$$

We will now take a look at the charge conjugation and investigate the interaction of a particle of opposite charge with an electro-magnetic field. Starting again from the Dirac equation and exchanging $e\rightarrow-e$ we find that the charge conjugate wave-function $\psi^c(\vec{x},t)$ must satisfy:

$$\left(\gamma^0\left[\mathrm{i}\frac{\partial}{\partial t}+e\phi(\vec{x},t)\right]-\gamma^i\left[\mathrm{i}\frac{\partial}{\partial x_i}+eA_i(\vec{x},t)\right]-m_0\right)\psi^c(\vec{x},t)=\vec{0} \qquad (11.3.503)$$

For our particular representation of the γ matrices we have the following properties (we change the notation for the complex conjugate to avoir the confusion with the notation of the self adjoint spinor):

$$\gamma^{0*}=\gamma^0,\gamma^{1*}=\gamma^1,\gamma^{2*}=-\gamma^2,\gamma^{3*}=\gamma^3 \qquad (11.3.504)$$

Then taking the complex conjugate of:

$$\left(\mathrm{i}\gamma^\mu\frac{\partial}{\partial x_\mu}-\gamma^\mu eA_\mu-m_0\right)\psi(\vec{x},t)=\vec{0} \qquad (11.3.505)$$

and expanding we get (and using the γ matrices properties too):

$$\begin{aligned}&\left(-\gamma^0\left[\mathrm{i}\frac{\partial}{\partial t}+e\phi(\vec{x},t)\right]+\gamma^1\left[\mathrm{i}\frac{\partial}{\partial x_1}\;+eA_1(\vec{x},t)\right]-\gamma^2\left[\mathrm{i}\frac{\partial}{\partial x_2}+eA_2(\vec{x},t)\right]\right.\\&\left.+\gamma^3\left[\mathrm{i}\frac{\partial}{\partial x_3}+eA_3(\vec{x},t)\right]-m_0\right)\psi^*(\vec{x},t)=\vec{0}\end{aligned} \qquad (11.3.506)$$

Now multiplying both sides with γ^2, and remember that $\gamma^\mu\gamma^\nu=-\gamma^\nu\gamma^\mu$ and :

$$\begin{aligned}&\left(-\gamma^2\gamma^0\left[\mathrm{i}\frac{\partial}{\partial t}+e\phi(\vec{x},t)\right]+\gamma^2\gamma^1\left[\mathrm{i}\frac{\partial}{\partial x_1}\right.+eA_1(\vec{x},t)]-\gamma^2\gamma^2\left[\mathrm{i}\frac{\partial}{\partial x_2}+eA_2(\vec{x},t)\right]\\&+\gamma^2\gamma^3\left[\mathrm{i}\frac{\partial}{\partial x_3}+eA_3(\vec{x},t)\right]-\gamma^2m_0\right)\psi^*(\vec{x},t)=\vec{0}\end{aligned} \tag{11.3.507}$$

Hence:

$$\begin{aligned}&\left(\gamma^0\gamma^2\left[\mathrm{i}\frac{\partial}{\partial t}+e\phi(\vec{x},t)\right]-\gamma^1\gamma^2\left[\mathrm{i}\frac{\partial}{\partial x_1}\right.+eA_1(\vec{x},t)]-\gamma^2\gamma^2\left[\mathrm{i}\frac{\partial}{\partial x_2}+eA_2(\vec{x},t)\right]\\&-\gamma^3\gamma^2\left[\mathrm{i}\frac{\partial}{\partial x_3}+eA_3(\vec{x},t)\right]-\gamma^2m_0\right)\psi^*(\vec{x},t)=\vec{0}\end{aligned} \tag{11.3.508}$$

Therefore:

$$\left(\gamma^0\left[\mathrm{i}\frac{\partial}{\partial t}+e\phi(\vec{x},t)\right]-\gamma^i\left[\mathrm{i}\frac{\partial}{\partial x_i}+eA_i(\vec{x},t)\right]-m_0\right)\gamma^2\psi^*(\vec{x},t)=\vec{0} \tag{11.3.509}$$

comparing this result with:

$$\left(\gamma^0\left[\mathrm{i}\frac{\partial}{\partial t}+e\phi(\vec{x},t)\right]-\gamma^i\left[\mathrm{i}\frac{\partial}{\partial x_i}+eA_i(\vec{x},t)\right]-m_0\right)\psi^c(\vec{x},t)=0 \tag{11.3.510}$$

we can readily identify:

$$\psi^c(\vec{x},t)=\gamma^2\psi^*(\vec{x},t) \tag{11.3.511}$$

Again we can use the arbitrary phase which we now take to be i, causing the combination $\mathrm{i}\gamma^2$ to be real:

$$\psi^c(\vec{x},t)=\mathrm{i}\gamma^2\psi^*(\vec{x},t) \tag{11.3.512}$$

We may stop here but there are some traditions that consist to write the C operator otherwise. Let us see how...! Rewriting this expression using the definition of the adjoint spinor (see page 5178):

$$\bar{\psi}^T\equiv\left(\psi^\dagger\gamma^0\right)^T=\gamma^{0T}\left(\psi^\dagger\right)^T=\gamma^0\psi^*\Rightarrow\psi^*=\gamma^0\bar{\psi}^T \tag{11.3.513}$$

yields the widely used expression for $\psi^c(\vec{x},t)$:

$$\boxed{\psi(\vec{x},t)\xrightarrow{C}\psi^c(\vec{x},t)=\mathrm{i}\gamma^2\psi^*(\vec{x},t)=\mathrm{i}\gamma^2\gamma^0\bar{\psi}^T(\vec{x},t)=C\bar{\psi}^T(\vec{x},t)} \tag{11.3.514}$$

Therefore we have proven (using another common notation in textbooks):

$$\mathcal{C}\mathcal{L}_{\text{Dirac}}\left(x^\mu\right)\mathcal{C}^{-1}=\bar{\mathcal{L}}_{\text{Dirac}}\left(x^\mu\right) \tag{11.3.515}$$

The time-reflection transformation takes the coordinate $x=(x_0,\vec{x})$ to $x'=(-x_0,\vec{x})$. This transformation can be written:

$$x'^\nu=a^\nu_\mu x^\mu \quad \text{with} \quad a^\nu_\mu=\begin{pmatrix}-1&0&0&0\\0&1&0&0\\0&0&1&0\\0&0&0&1\end{pmatrix} \tag{11.3.516}$$

Denoting $\psi'(x') \equiv \psi'(-x_0, \vec{x})$ the free time-reflected wave function, we attempt to construct it under the form (having in mind that time inversion intuitively should give us the antipartcle, hence we take the complex conjugate!):

$$\psi'(x') = T\psi^*(x) \quad \Rightarrow \quad \psi^*(x) = T^{-1}\psi'(x') \tag{11.3.517}$$

where T is a 4×4 constant matrix and $\psi(x)$ is the solution of the free Dirac equation with (we keep the notation used for the charge conjugation to denoted the complex conjugate to avoid any confusion with the adjoint spinor!):

$$\left(-\mathrm{i}\frac{\partial}{\partial x_\mu}\gamma^{\mu *} - m_0\right)\psi^*(x) = \vec{0} \quad \Rightarrow \quad \left(-\mathrm{i}\frac{\partial}{\partial x'_\nu}a_\mu^\nu\gamma^{\mu *} - m_0\right)T^{-1}\psi(x') = \vec{0} \tag{11.3.518}$$

Multiplying to the left by T we get:

$$\left(-\mathrm{i}\frac{\partial}{\partial x'_\nu}a_\mu^\nu T\gamma^{\mu *}T^{-1} - m_0\right)\psi'(x') = \vec{0} \tag{11.3.519}$$

And the reader must not forget that what we want is to fall back on the standard free Dirac equation:

$$\left(\mathrm{i}\frac{\partial}{\partial x'_\nu}\gamma^\nu - m_0\right)\psi'(x') = \vec{0} \tag{11.3.520}$$

And for that, it means we are looking for a T such that:

$$a_\mu^\nu T\gamma^{\mu *}T^{-1} = -\gamma^\nu \tag{11.3.521}$$

Recalling that $\gamma^{\mu *} = \gamma^\mu$ for $\mu = 0,1,3$ and $\gamma^{2*} = -\gamma^2$, the above conditions reduce to $T\gamma^i = \gamma^i T$ for $i = 0,2$ and $T\gamma^j = -\gamma^j T$, $j = 1,3$.

✍**Example:**

Consider the case γ^0. Therefore as $\gamma^{0*} = \gamma^0$:

$$a_\mu^\nu T\gamma^{\mu *}T^{-1} = -\gamma^\nu \Rightarrow a_0^\nu T\gamma^{0*}T^{-1} = -\gamma^\nu \Rightarrow a_0^\nu T\gamma^0 T^{-1} = -\gamma^\nu$$

For $\nu = 0$ we then have for example:

$$a_0^0 T\gamma^0 T^{-1} = -\gamma^0 \Rightarrow -T\gamma^0 T^{-1} = -\gamma^0 \Rightarrow T\gamma^0 T^{-1} = \gamma^0$$

Multiplying every side of the equality by T on the right, we get:

$$T\gamma^0 = \gamma^0 T$$

After some trial and errors we can found that the matrix:

$$T = \mathrm{i}\gamma^1\gamma^3 \tag{11.3.522}$$

satisfies the required conditions and we have thus:

$$\psi'(-x_0, \vec{x}) = \mathrm{i}\gamma^1\gamma^3\psi^*(x_0, \vec{x}) \tag{11.3.523}$$

This yields the widely used expression for $\psi^t(\vec{x},t)$:

$$\boxed{\psi(\vec{x},t)\xrightarrow{T}\psi^t(\vec{x},t)=\mathrm{i}\gamma^1\gamma^3\psi^*\left(x_0,\vec{x}\right)}\tag{11.3.524}$$

Therefore we have proven (using another common notation in textbooks):

$$\mathcal{T}\mathcal{L}_{\text{Dirace}}\left(t,x^i\right)\mathcal{T}^{-1}=\bar{\mathcal{L}}_{\text{Dirac}}\left(-t,x^i\right)\tag{11.3.525}$$

Remark

Combining the symmetries P and T one can construct the wave function of an electron evolving backward in space-time:

$$\begin{aligned}\psi^{PT}(-x^\mu)=PT\psi(x^\mu)&=\gamma^0\left[\mathrm{i}\gamma^1\gamma^3\psi^*(x^\mu)\right]\\&=\gamma^5\mathrm{i}\gamma^2\psi^*(x^\mu)\\&=\gamma_5\psi^c(x^\mu)\end{aligned}$$

where we introduced the wave-function of the positron. Thus the wave function of a (right-handed) positron is that of a (left-handed) electron moving backward in space-time (up to an irrelevant phase factor)!

Caution! It's not because a mathematical model is CPT symmetric that the reality is symmetric! A famous example is the Kaon decays. Theoretical models didn't first predict C,P + CP, T violations for the Kaons. Theoretical physicists had to change the theoretical model to be compliant with the evidence based science (i.e. experiments). The theoretical changes necessaries to take into account the Kaon decays symmetry violation observations leaded the physicists Makoto Kobayashi and Toshihide Maskawa in 11973 (both awarded by a Nobel Price in physics in 12008) to assume the existence of 4 supplementary quarks to the models assuming at their time having only 2 quarks (hence a total of 6 quarks still actually confirmed by experimental observations!).

11.4. Nuclear Physics

NUCLEAR PHYSICS is the field of physics that studies the constituents and interactions of atomic nuclei. The most commonly known applications of nuclear physics are nuclear power generators but the research has provided application in many fields, including those in nuclear medicine (tracers) and magnetic resonance imaging, nuclear weapons, nuclear batteries as betavoltaic devices (we will come back on this subject later), ion implantation in materials engineering, radiocarbon dating in geology and archaeology, food or water sterilization, etc.

> *Anyone who expects a source of power from the transformations of these atoms is talking moonshine.*
>
> Ernest Rutherford

> *There is not the slightest indication that nuclear energy will ever be obtainable - it would mean that the atom would have to be shattered at will.*
>
> Albert Einstein

These two quotes provide once again evidence that opinions, even from the best scientists, are not reliable when faced to scientific facts and time...

11.4.1 Nuclear Weapon

Without wishing to make any confusion, we consider as essential, at the time when nuclear weapon serves as a dissuasion vector and thus as element of global stability (but also threat of global destruction ...), for the general culture of the engineer to know some basic properties of the atomic fission bomb. We'll exceptionally in this small subsection without mathematics (mathematical developments of nuclear weapons and nuclear power plants will be presented during our study of neutronic further below) speak a little bit of this mass destruction weapon that often fascinates the young students.

For sure, we will study later theoretically a nuclear divergent chain reaction in a given closed constrained volume! However, the reader must not expect to gain the knowledge necessary to manufacture such a weapon since it doesn't appeal only to knowledge of physics, but also electronics, mechanics, chemistry, mathematics, etc.

About an explosion, usage has immediately propagate to compare the energy of a nuclear weapon than a well known explosive material: the Trinitrotoluene (TNT). This TNT provides

$4,200,000$ joules per kilo, but the energies of nuclear weapons are such high that it is more meaningful to evaluate them in thousands of tonnes - or kilotons of TNT (subsequently thermonuclear weapons represented a new leap in explosive energy: the practical unity of comparison is one million tonnes - megaton of TNT).

The fission of 56 grams of Uranium 235 or Plutonium 239 gives the equivalent of 1 kiloton with the fission of $1.44 \cdot 10^{23}$ atoms (this is not even an integer value of Avogadro's number !!).

The first known nuclear test explosion at Alamogordo in July 16, 11945 (holocene calendar) - was estimated at 20 kt, with good accuracy because it had been possible to set up multiple measuring devices.

Those of August 6, 11945 (holocene calendar) on Hiroshima (based on 63 kilograms of Uranium 235) and August 9 on Nagasaki (based on 5.8 kilograms of Plutonium 239) were first estimated as 20 kt (only a estimate of 900 grams is converted into pure energy during the explosion). Subsequently, and after a detailed study on the effects of the blast, their energies were respectively reduced to about 17 to 15 kt respectively. This, however, did not represented less of the equivalent of a load of TNT of a convoy of around $6,000$ trucks from the US Army.

Here is a very good diagram (sadly we have yet only a french version) both interesting and persuasive on the effects of an atomic bomb (for information a wind with a speed above $220\,[\text{km}\cdot\text{h}^{-1}]$ can lift an average human being from the ground):

Figure 11.88: Effects of fission weapon of 1 Mt as a function of the distance (source: Pour la science)

So in other words here is a summary and approximately the effects of a 1 Mt fission weapon exploding at 2,450 meters of altitude (knowing that today the Americans and the Russians have nuclear fusion weapons with firepower exceeding the 50 megatons...):

Up to 1.3 [km], everything is down, even reinforced buildings. Up to 4.8 [km], most factories and commercial buildings are destroyed; houses made of brick and wood are blow up, and debris scattered. Up to 7 [km], commercial sets of light structure and private residences are demolished. Heavier buildings are seriously damaged. Up to 9.5 [km], the walls of small vessels are reversed, private residences severely deteriorated. The breath (or pressure) is still powerful enough to kill the people who are outside (explosion of the lungs). Up to 18.6 [km], different buildings are damaged, the streets are littered with debris and glass tiles. Between 10 to 20 minutes after the explosion, the debris drawn into the depression of the stem of the mushroom, fall to the ground. Follow after 1 to 2 hours later, the debris being in the head of the mushroom.

Most of the effects shown in the diagram above are not proportional to the energy. There is therefore no need to make a simple multiplication for a weapon with multiple power that used for the above figure!

For people interested in mushroom size (...) here is a figure whose source in unknown:

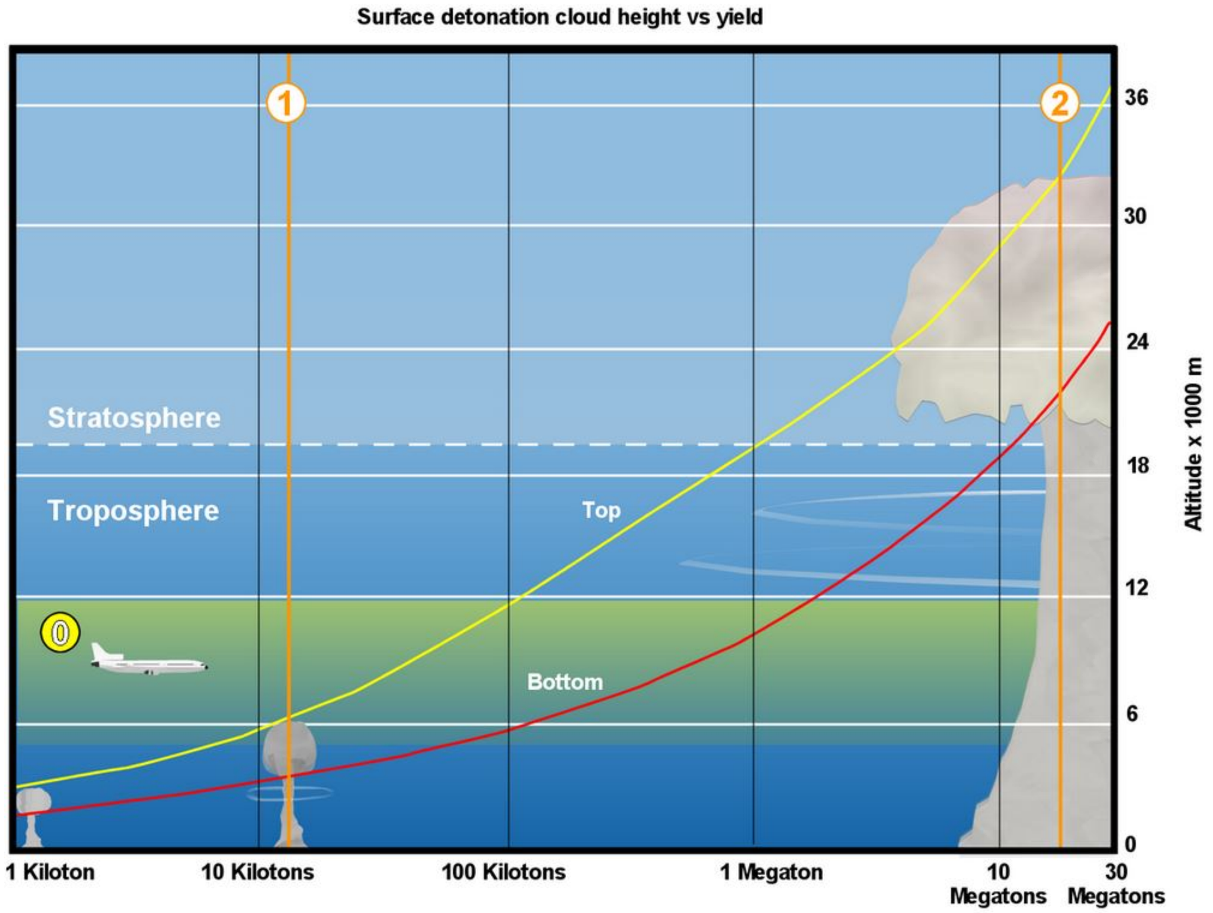

Figure 11.89: Mushroom size for Little Boy Hiroshima (1) and Castle Bravo (2)

Remark

For a nice little calculation on nuclear bombs using dimensional analysis the reader can refer to section Principles of Mechanics (see page 3081) where we give the expression of the energy of a nuclear bomb according to the estimated radius of the fireball.

Before we start the mathematical part, we emphasize and reiterate that we will limit ourselves only to theoretical developments made between 11890 and about the years 11935 according to holocene calendar (beyond the complexity of theories requires too many pages to a general textbook like this one).

11.4.2 Radioactivity

When we experimentally analyse radioactivity, we first perceive that the nucleus does not emits its elementary constituents. Then we discover new forces, that struggles and dominate in turn. Finally, new particles of matter, and even antimatter, appear. Deciphering these puzzles provided a coherent picture of the infinitely small world that radioactivity has revealed, a world where physical laws escape to the common intuition of daily practice of our macroscopic world.

From the start, the radioactivity has surprised. From the years 11900s (holocene calendar) it was known that radiation from Uranium and his descendants had three components, named "alpha" (α), "beta" (β), and "gamma" (γ) separable by the action of a magnetic field as shown symbolically in the image below:

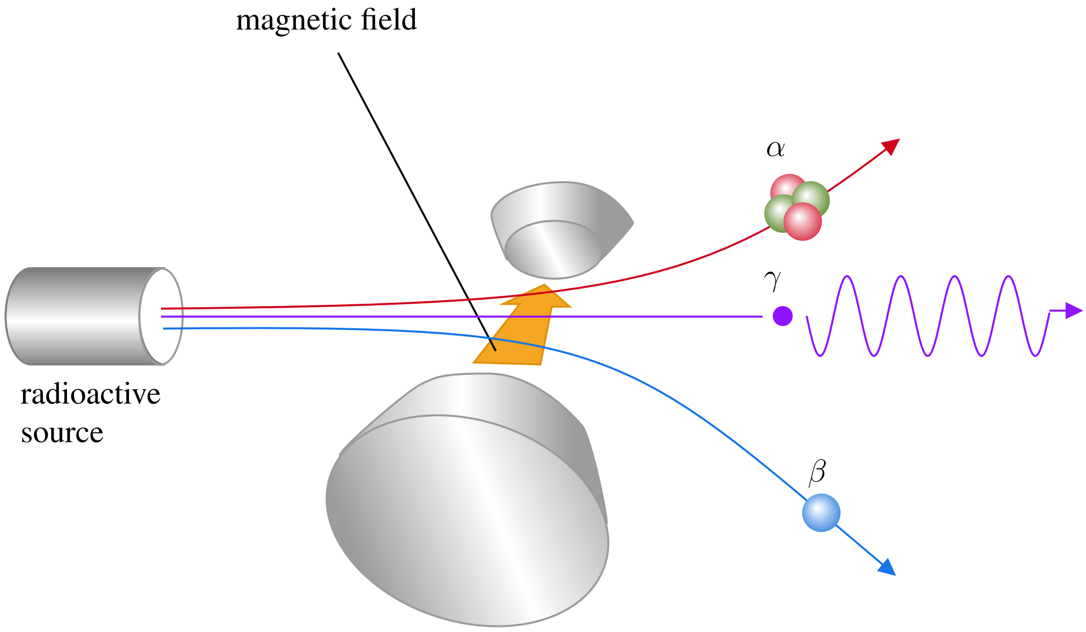

Figure 11.90: Separation of radiation using a magnetic field (source: Pour la Science)

Later, it was shown that the alpha radioactivity was the emission of a Helium nuclei (two protons and two neutrons), beta radiation the emission of electrons. From these observations, it was assumed that the nucleus was formed of these three types of particles (protons, neutrons and electrons), which is not the case: the components of nucleus seems to have been discovered by J. Chadwick only in 11932 (holocene calendar).

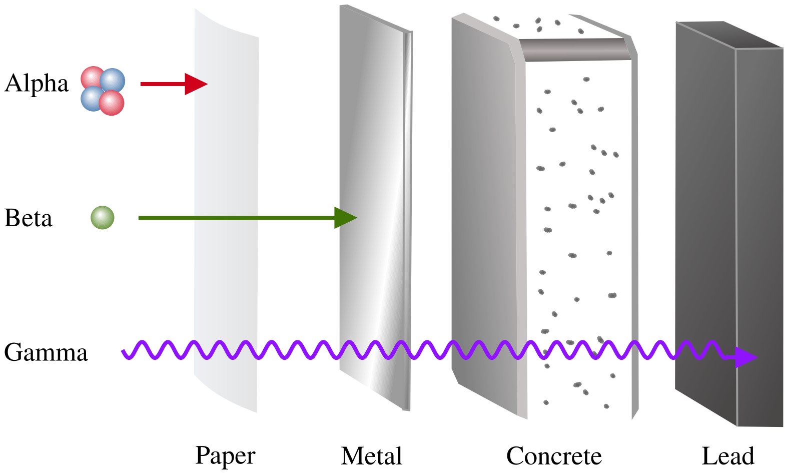

Figure 11.91: Typical radiation penetration

So why do radioactive nuclei not emit single protons or neutrons? How do nuclei eject something else than their fundamental constituents? These issues must be preceded by another, perhaps more fundamental, why some nuclei are radioactive? The response is the same for all spontaneous physical phenomena! The apple falling from the tree, for example: it is because the system can reach a more stable state by losing potential energy, the excess energy escaping in the form of kinetic energy, i.e. in the form of movement.

This reason also explains why the isotopes emit no protons or neutrons alone because often at the quantum structure of the nucleus, it is more favourable at the energy level to emit a small nucleus or to change a proton into a neutron (the quantum study of the nucleus exceeds the mathematical framework of the topics covered in this textbook actually).

Definitions (#11.4.509):

D1. Any chemical element (see chapter Chemistry page 6122) is characterized in the chemical point of view by its number of protons Z named "atomic number".

D2. The "mass number" A is by definition the number of protons Z summoned by the number of neutrons N for the given chemical element. Thus, the latter is completely characterized if we know its name or atomic number Z and its number N of neutrons or its mass number A. We usually denote any element in the form:

$$ {}_{Z}^{A}\mathrm{X}_{N} = {}_{Z}^{Z+N}\mathrm{X}_{N} \tag{11.4.1} $$

The chemical elements of the same species (same Z) may have different numbers of neutrons N, that is to say therefore different mass numbers A, then we speak of "isotopes" or "nuclides" (today this seems obvious as a definition but it took many years of research to get to this concept and we own this particularly to the works of Niels Bohr). The chemical elements which have the same A are named "isobars".

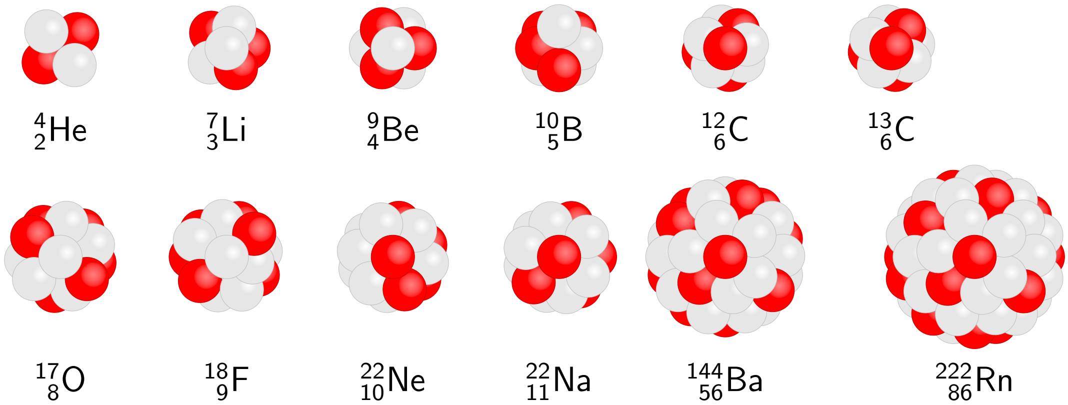

Figure 11.92: **Some nucleus (and isotopes) and their technical notation**

For a much more exhaustive list see the table of isotopes below:

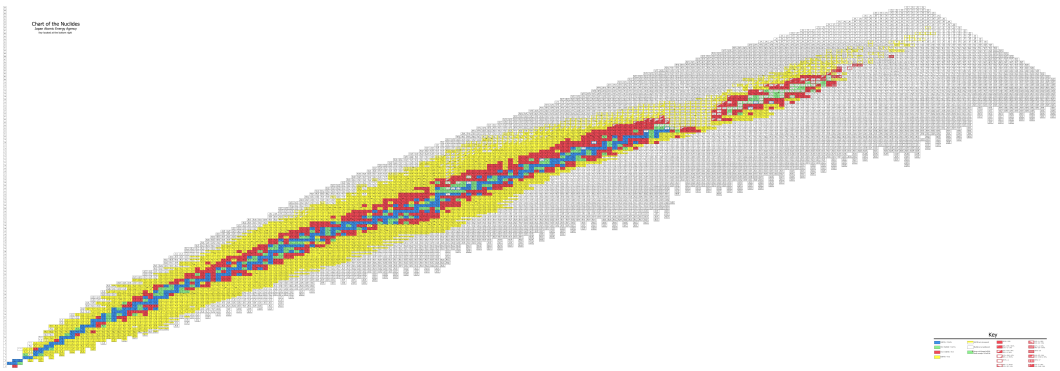

Figure 11.93: **Table of isotopes (zoom to see the details)**

Obviously, the nuclear energy (of the nucleus) associated with the same chemical element differs depending on the mass number A and we will prove that there is number A for which energy this minimal. Isotopes for which the energy is not a minimum may, for some of them and spontaneously, release the excess energy by doing a form of disintegration.

For example, according to a common misconception there is not only one type of Iron, but multiples:

Isotope	**Abondance** (molar percentage)
^{54}Fe	35%
^{56}Fe	36%
^{57}Fe	10%
^{58}Fe	4%
^{60}Fe	traces

Table 11.14: **Different isotopes of Iron**

D3. The property of certain atoms to spontaneously change the structure of their nuclei to reach a lower energy level, more fundamental, is named "radioactivity". We then talk about "radio-isotopes" for the atoms involved.

The chemical properties of an atom depend (see section Corpuscular Quantum Physics page 4675) on the number and arrangement of electrons in the electronic cloud (corresponding to the number of proton Z for non-ionized atoms). Thus all isotopes of the same element have the same chemical properties (it is this chemical characteristic which is the basis for nuclear medicine). These are sort of "brothers" atoms. However, the small difference in mass of the nucleus makes that their physical properties differ somewhat like the different type of water properties used to date air in ice cores:

Type of water	**Notation**	**Freezing point**	**Boiling point**
Water (dihydrogen monoxide)	H_2O	0.00 °C	100.00 °C
Heavy ^{18}O Water	$H_2{}^{18}O$	0.28 °C	100.14 °C
Semi-Heavy Water (deuterium oxide)	HDO	2.04 °C	100.70 °C
Heavy Water	$^2H_2O, D_2O$	3.1 °C	101.42 °C

Table 11.15: **Examples of isotopes that change the properties of a medium ("thermal isotope")**

Remark

Scientists have identified 118 eleemnts and approximately $1,500$ isotopes, among which 300 are natural (the others are artificially generated in nuclear reactors or accelerators). There are isotopes that are stable and some that are unstable (i.e. radio-isotopes). In Nature the proportion of isotopes of a same element in a material (even living one) varies depending on many factors.

D4. The "isotones" are the isotopes of various chemical elements (different Z) with the same number of neutrons N.

Rather than speak of "chemicals elements" when we actually are implicitly referring to the nucleus, the term "nuclide" is preferred.

The smallness of atoms is an obvious problem of mass measurement. That is why it was preferred by physicists and chemists to develop an atomic mass system which is a system of numbers proportional to the real mass of the atoms.

Since there are infinitely many possible systems, one was chosen judiciously as a reference and is the number 12 for the carbon-12 isotope (for more details see the section of Analytical Chemistry):

$$^{12}\text{C} = 12.00000\;[\text{amu}] \tag{11.4.2}$$

where "amu" is the abbreviation of "atomic mass units".

This choice has for interesting consequence to give to the proton and neutron an atomic weight near to the unit.

We can therefore connect the I.S.Q. system (see section Principia page 3075) with the system of atomic mass units (amu).

D5. A group of chemical compounds only differing in their isotopic composition (for example normal water and heavy water) is named an "isotopologue".

The fact that chemical compounds can be made of isotopes is experimentally observed as changing a little bit the properties of chemical reactions (like speed of the chemical reaction or its enthalpy) and also of gas behaviours!

D6. The "atomic mass unit" is defined as the mass of the $1/12$ of the atom of carbon ^{12}C, we have (the mass of the electrons is neglected as very small compared to that of nucleons):

$$1\,[\text{uma}]=\frac{1}{12\,[\text{nucleons}\cdot\text{at.}^{-1}]}\frac{12\,[\text{g}\cdot\text{mole}^{-1}]}{N_{\text{A}}}=\frac{1}{6.0221367\cdot 10^{23}}=1.6605402\cdot 10^{-24}\,[\text{g}] \tag{11.4.3}$$

Therefore the uma mass of the proton is equal to:

$$m_{\text{uma,p}}=\frac{1.6726231\cdot 10^{-24}\,[\text{g}]}{1.660.5402\cdot 10^{-24}\,[\text{g}]}\cong 1.007276468\,[\text{uma}] \tag{11.4.4}$$

for the admitted value in practice the reader must referred to the literature of the ad hoc international norms (because it varies depending on the new versions of international norms).

However the reader must be careful, though the molar mass of a different isotope than ^{12}C by adding the masses of the nucleons (protons and neutrons) that make up its nucleus because we must take into account the mass defect (a concept that we will see further below).

The mass can also be expressed in energy units because there is a mass-energy equivalence as we have proved it in the section of Special Relativity (see page 5679) from the relation $E=mc^2$. The energy units used in nuclear physics is often the "electron volt".

D7. An "electron-volt" denoted [eV] is the energy acquired by an elementary charge subject to a potential difference of 1 [V].

Thus, according to the relation between energy and the electrostatic potential $E=qU$ (see section Electrostatics page 4005), we have:

$$\boxed{1\,[\text{eV}]=1.60217733\cdot 10^{-19}\,[\text{J}]} \tag{11.4.5}$$

We get from this since the speed of light in vacuum is almost equal to $c=299,792,458\,[\text{m}\cdot\text{s}^{-1}]$:

$$1\,[\text{g}]=8.987551\cdot 10^{13}\,[\text{J}]=5.60959\cdot 10^{32}\,[\text{eV}]\Rightarrow 1\,[\text{uma}]=931.49432\,[\text{MeV}] \tag{11.4.6}$$

By mass–energy equivalence, the electron-volt is also a unit of mass. It is common in particle physics, where units of mass and energy are often interchanged, to express mass in units of eV$/c^2$. It is common to simply express mass in terms of "eV" as a unit of mass, effectively using a system of natural units with c set to 1 (see section Principia page 3124). The mass equivalent of 1 eV$/c^2$ is:

$$1\,[\text{eV}\cdot c^{-2}]=\frac{(1.60217646\cdot 10^{-19}\,[\text{C}])\cdot 1\,[\text{V}]}{(2.99792458\cdot 10^{8}\,[\text{m}\cdot\text{s}^{-1}])^2}\cong 1.783\times 10^{-36}\,[\text{kg}] \tag{11.4.7}$$

Again, for the admitted value in practice the reader has to refer to the literature of the ad hoc international norms (because it varies depending on the new versions of these norms).

Remark

Practising astrophysicists and plasma physicists routinely refer to temperatures in units of [eV] or [keV], even thought this is wrong, because temperature is not dimensionally equivalent to energy. Nevertheless, they still do it, with the Boltzmann constant being implicitly included in the conversion. Here are formulas for temperature in Kelvin to [keV] conversion:

$$E([\text{eV}])=\frac{kT}{e} \tag{11.4.8}$$

because 1 [eV] is by definition the energy required to move a charge e through a potential difference of 1 [V] and is equal to $1.6\cdot 10^{-19}$ [J]. Therefore:

$$T([\text{eV}])=\frac{k}{e}T=8.625\cdot 10^{-5}\cdot T \tag{11.4.9}$$

The use of stable isotopes is widely used for health checks, the quality or origin of foods and compliance with their labels - because the natural proportions are not the same from one geographical point to another and with or without pesticides- as well as doping controls (to check if elements in the blood are not of industrial origin), in criminology (origin of corpses).

11.4.2.1 Disintegration

Some nucleus therefore have the property of spontaneously change their internal structure to achieve a basic level of energy. This transformation is accompanied by the emission of particles and / or electromagnetic radiation. The residual core can be radioactive too and process to other transformations afterwards or be stable.

The radioactive decay of an isotope is a random phenomenon and we can never tell when a nucleus will disintegrate (probability no memory effect).

Remark

To prove this assertion, the reader may refer to the section of Quantitative Management in the subsection of Queuing Theory, in particular modelling arrivals (see page 8145). Indeed, the development is identical in all point but only the object of study changes (that are no longer phone calls but disintegration). Thus, we proved that under certain assumptions the phenomenon follows a Poisson law and we will prove a little bit afterwards that it has no memory (see page 8149)!

We can only give the probability of disintegration (decay) per unit time. This probability is given by the "disintegration constant" and has for unit the inverse of time: $\lambda\,[\mathrm{s}^{-1}]$. This constant can be calculated as we have already proved it during our the study of the tunnel effect in the section of Wave Quantum Physics (see page 4840).

The radioactive constant varies for all known isotopes:

$$1.57\cdot 10^{-18}\,[\mathrm{s}^{-1}]\leq\lambda\leq 3\cdot 10^{6}\,[\mathrm{s}^{-1}] \qquad (11.4.10)$$

Given now $N(t)$ the initial stock of atoms of a radioactive isotope at time t. The number of atoms disintegrating during the infinitesimal time $\mathrm{d}t$ is equal to:

$$\lambda N(t)\mathrm{d}t \qquad (11.4.11)$$

leading to a decrease in the stock obviously equal to:

$$-\lambda N(t)\mathrm{d}t \qquad (11.4.12)$$

The decay differential equation (see section Differential and Integral Calculus page 1609) is thus written:

$$\mathrm{d}N=-\lambda N\mathrm{d}t \qquad (11.4.13)$$

or:

$$\frac{\mathrm{d}N}{\mathrm{d}t}+\lambda N=0 \qquad (11.4.14)$$

which has the simple solution (see section Differential and Integral Calculus page 1609):

$$\boxed{N(t)=N_0e^{-\lambda(t-t_0)}} \qquad (11.4.15)$$

with $N_0=N(t_0)$ being the initial stock of nucleus at time t_0. So notice that as the decay is an inverse exponential, there is no such thing a "total life" for isotopes!

Remark

$N(t)$ does not represent the number of atoms remaining at time t but the most likely number of radioactive atoms remaining at time t !!

In the practice, the measurement of the decay constant is done thanks the decrease of the activity (see below) of the individual isotope.

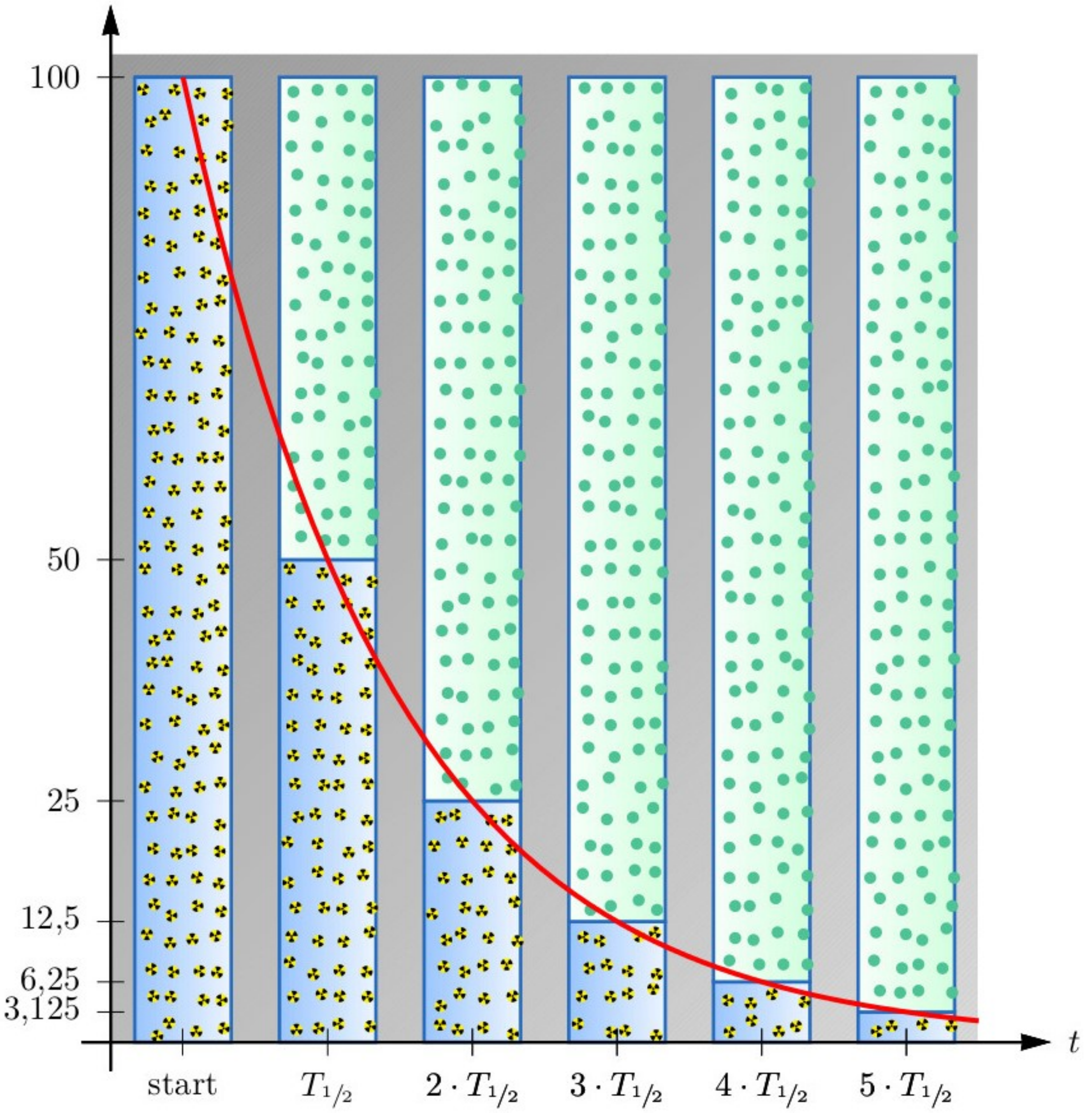

Figure 11.94: **Illustrated radioactivity half-life decay (author: Svend Tveskæg)**

11.4.2.1.1 Half-life and Mean life isotope

Definition (#11.4.510): The "half-life period" or just "half-life" $T_{1/2}$ of an isotope is the average time that it takes for 50% of the radioactive nuclei stock of a given isotope to disintegrate:

$$\frac{N(t=T_{1/2})}{N_0}=\frac{1}{2}=e^{-\lambda T_{1/2}} \Rightarrow T_{1/2}=\frac{\ln(2)}{\lambda} \tag{11.4.16}$$

Thus we have a very important relation between the half-life period and the decay constant:

$$\boxed{T_{1/2}=\frac{\ln(2)}{\lambda}} \tag{11.4.17}$$

The probability for decay can be expressed as a distribution function:

$$f_{\text{decay}}(t)=C^{te}e^{-\lambda t} \tag{11.4.18}$$

To normalize this distribution function:

$$\int\limits_0^{+\infty} f_{\text{decay}}(t)\mathrm{d}t=\int\limits_0^{+\infty} C^{te}e^{-\lambda t}\mathrm{d}t=-\frac{1}{\lambda}C^{te}e^{-\lambda t}\Big|_0^{+\infty}=\frac{C^{te}}{\lambda}=1 \tag{11.4.19}$$

Hence:

$$f_{\text{decay}}(t)=\lambda e^{-\lambda t} \tag{11.4.20}$$

The probability that a given particle will decay within time t is given by the integral of the decay distribution function from 0 to t. This is not the quantity which we wish to calculate if we want the average time the particle will exist without decaying. The probability that a particle is not decayed is one minus the probability that it will decay. The probability that a particle will remain at time t is then:

$$P_u(t)=1-\int\limits_0^{t}\lambda e^{-\lambda t'}\mathrm{d}t'=1+e^{-\lambda t'}\Big|_0^{t}=e^{-\lambda t} \tag{11.4.21}$$

Definition (#11.4.511): Given an assembly of elements, the number of which decreases ultimately to zero, the "mean lifetime" τ, is the expected value of the amount of time before an object is removed from the assembly. Specifically, if the individual lifetime of an element of the assembly is the time elapsed between some reference time and the removal of that element from the assembly, the mean lifetime is the arithmetic mean of the individual lifetimes.

Starting from density probability of decay:

$$f_{\text{decay}}(t)=\lambda e^{-\lambda t} \tag{11.4.22}$$

Exponential decay is therefore scalar multiple of the statistical exponential distribution (i.e. the individual lifetime of each object is exponentially distributed), which has a well-known expected value (see section Statistics page 751):

$$\tau=\langle t\rangle=\int\limits_0^{+\infty}\lambda t e^{-\lambda t}\mathrm{d}t=\frac{1}{\lambda} \tag{11.4.23}$$

So the mean lifetime for particle decay is given by:

$$\boxed{\tau=\frac{1}{\lambda}=\frac{T_{1/2}}{\ln(2)}\cong\frac{T_{1/2}}{0.693}} \tag{11.4.24}$$

A quantity may decay via two or more different processes simultaneously. In general, these processes (often named "decay modes", "decay channels", "decay routes" etc.) have different probabilities of occurring, and thus occur at different rates with different half-lives, in parallel. The total decay rate of the quantity N is given by the sum of the decay routes; thus, in the case of two processes:

$$-\frac{\mathrm{d}N(t)}{\mathrm{d}t}=N\lambda_1+N\lambda_2=(\lambda_1+\lambda_2)\,N \tag{11.4.25}$$

Therefore:

$$N(t)=N_0e^{-(\lambda_1+\lambda_2)t}=N_0e^{-(\lambda_c)t} \tag{11.4.26}$$

where the sum of $\lambda_1+\lambda_2$ is treated as a new total decay constant λ_c. Using the same reasoning as before we get the total half-time (also named "partial half-life"):

$$T_{1/2}=\frac{\ln(2)}{\lambda_c}=\frac{\ln(2)}{\lambda_1+\lambda_2} \tag{11.4.27}$$

As:

$$\tau=\frac{1}{\lambda}=\frac{T_{1/2}}{\ln(2)} \tag{11.4.28}$$

The latter can be rewritten:

$$T_{1/2}=\frac{\ln(2)}{\dfrac{\ln(2)}{T_{1/2}^1}+\dfrac{\ln(2)}{T_{1/2}^2}}=\frac{1}{\dfrac{1}{T_{1/2}^1}+\dfrac{1}{T_{1/2}^2}} \tag{11.4.29}$$

As:

$$\frac{1}{\tau_c}=\lambda_c=\lambda_1+\lambda_2=\frac{1}{\tau_1}+\frac{1}{\tau_2} \tag{11.4.30}$$

We also have the following "partial mean life":

$$\tau_c=\frac{\tau_1\tau_2}{\tau_1+\tau_2} \tag{11.4.31}$$

Remark

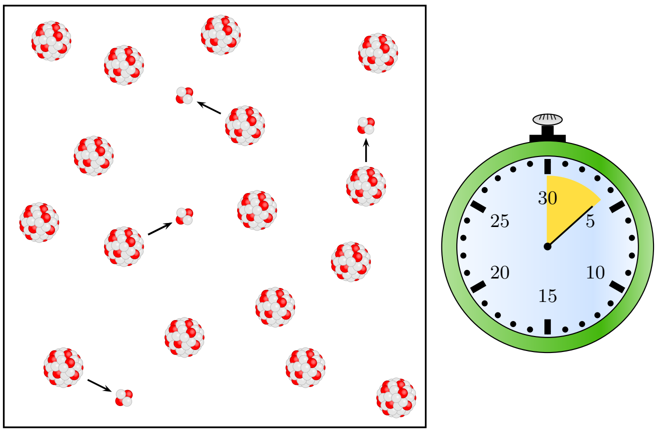
In 11913 (holocene calendar), Pierre Curie and M. Kamerlingh Onnes measured the rate of decay of radium at room temperature and after being cooled in liquid hydrogen. Their conclusion was that the decay rate was entirely independent of temperature. Since then, numerous investigations have shown that alpha and beta decays are not influenced by external conditions such as temperature, air pressure but only by the surrounding material in some very extreme situations (like near absolute zero). By contrast, decays that proceed by electron capture are known to be susceptible to their environment and so have been placed in a different category.

11.4.2.2 Activity

Definition (#11.4.512): The "activity" of a radioactive source is the number of disintegrations per time unit.

Remark

Its unit of measurement is the "Becquerel" denoted [A]=[Bq]. One Becquerel thus corresponding to one disintegration per second.



$\Delta n = 4$ disintegration ins $\Delta t = 4$ [s]

$$A = \frac{\Delta n}{\Delta t} = 1 \text{ [Bq]}$$

The old unit of measurement of radioactivity was the "Curie" denoted [Ci]. The Curie was defined initially as the activity of about one gram of radium, natural element that we find in the soil with uranium. This unit is much larger than the previous one because, by definition 1 [Ci] is equal to 37 billion disintegrations per second:

$$1 \text{ [Ci]} = 3.7 \cdot 10^{10} \text{ [Bq]} \tag{11.4.32}$$

The activity is obtained by the time derivative of the stock atoms of a given sample:

$$A(t) = -\frac{\mathrm{d}N(t)}{\mathrm{d}t} = \lambda N_0 e^{-\lambda(t-t_0)} = \lambda N(t) \tag{11.4.33}$$

The relation, named "equation of activity":

$$A = \lambda N \tag{11.4.34}$$

thus shows that the activity of a given number of N atoms of a radioactive isotope is proportional to that number and inversely proportional to the half-life of the isotope (by the relation seen above between the radioactive constant and the half-life period).

✍**Example:**

One gram of $^{225}\mathrm{Ra}$ contains (the reader must regularly refer to the common international standards for the values of the constants used!):

$$\frac{1\,[\text{g}]\cdot 6.0221267\cdot 10^{23}\,[\text{at}\cdot\text{mole}^{-1}]}{226.0256\,[\text{g}\cdot\text{mole}^{-1}]}\cong 2.664\cdot 10^{21}\,[\text{atoms}] \tag{11.4.35}$$

Therefore the activity of this gram is, knowing experimentally that $T_{1/2}=1,600\,[\text{years}]$, equal to:

$$A=\lambda N=\frac{\ln(2)}{T_{1/2}}N=\frac{\ln(2)}{1600\cdot 365.256\cdot 24\cdot 60\cdot 60}\cdot 2.664\cdot 10^{21}=3.66\cdot 10^{10}\,[\text{Bq}] \tag{11.4.36}$$

By the same reasoning (that we can detailed on reader request as always in this textbook), we show that the activity over time follows the same exponential law of the number of nuclides:

$$\boxed{A(t)=A_0e^{\lambda(t-t_0)}} \tag{11.4.37}$$

with:

$$A_0=A(t_0)=\lambda N_0 \tag{11.4.38}$$

Experimentally to determine the half-life period of an isotope we proceed as following:

1. We choose a pure as possible sample of an isotope which we wish to determine the half-life period.
2. At the time t_0 we measure thanks to a detector for a fixed time interval time Δt the number of disintegrations. We then have the number of decays during a time interval at the start of experiment (the unit of measurement is then decays and not the number of disintegrations per second).
3. Then, for each consecutive Δt (time interval is fixed) we measure the number of disintegrations during this time interval. This gives us a series of measures the number of decays observed for $\Delta t_1,\Delta t_2,\Delta t_3,\ldots$
4. To the set of all decay measurements, we remove the laboratory background noise (as the whole environment is radioactive).

As:

$$A(t)\Delta t=A(t_0)\Delta te^{-\lambda(t-t_0)} \tag{11.4.39}$$

By taking the neperian logarithm we get:

$$\ln(A(t)\Delta t)=\ln(A(t_0)\Delta t)-\lambda(t-t_0)=-\lambda(t-t_0)+\ln(A(t_0)\Delta t) \tag{11.4.40}$$

Thus:

$$\ln(A(t)\Delta t)=-\lambda t'+\ln(A(t_0)\Delta t) \tag{11.4.41}$$

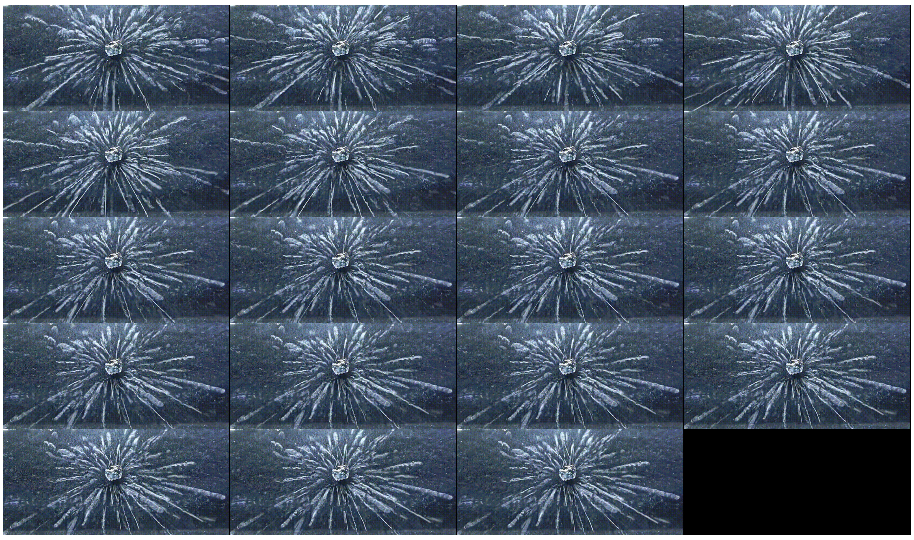
So this is the equation of a straight line of slope $-\lambda$ and intercept $\ln(A(t_0)\Delta t)$. Thus, the decay constant is immediately measured and we quickly deduced the period of half-life using the relation proved earlier above:

$$T_{1/2}=\frac{\ln(2)}{\lambda} \tag{11.4.42}$$

In the gallery below taken from https://www.youtube.com/watch?v=ZiscokCGOhs&t=250s we can see a sealed glass container that contains liquid alcohol at the top. Emanating alcohol vapors fill the whole volume of the container until they reach the bottom of the chamber maintained to a very cold temperature (-40 [°C]). Most of the vapour condenses on the glass surface creating a mist, but a small fraction of it stays in vapour form above the cold condenser. This creates a layer of unstable sursaturated vapour which can condense at any moment. When a charged particle crosses this vapor, it can knock electrons off the molecules forming ions. It causes the unstable alcohol vapor to condense around ions left behind by the travelling ionizing particle : the path of the particle in the matter is then revealed by a track composed of thousands droplets of alcohol.

Any charged particle is visible in a cloud chamber. The most common ones are alphas, electrons, positons, protons, nuclear charged fragment, muons (...). Theses particles come from natural cosmic and telluric background radiations or from close radioactive sources. They will all leave tracks of different shapes in the chamber, based on their charge, mass and speed. Electrons are the lightest particles and will be easily deflected by magnetic fields. Alphas and protons are much heavier and slower and will thus ionize more, causing denser track of droplets. Interactions of neutral particles like gamma rays or neutrons can be seen thanks to the charged particles they create in matter.

The gallery below is a subset of a 50 min video with an Uranium mineral. The small thickness of liquid alcohol on the mineral is enough to absorb a part of the energy of the alpha particles (their ranges in air for 5 [MeV] is 3-4 [cm].



11.4.2.2.1 Radiometric dating

"Radiometric dating", also named "radioactive dating" or "radioisotope dating" is a technique which is used to date materials such as rocks or carbon, in which trace radioactive impurities were selectively incorporated when they were formed. The method compares the abundance of a naturally occurring radioactive isotope within the material to the abundance of its decay products, which form at a known constant rate of decay. The use of radiometric dating was first published in 11907 (holocene calendar) by Bertram Boltwood and is now the principal source of information about the absolute age of rocks and other geological features, including the age of fossilized life forms or the age of the Earth itself, and can also be used to date a wide range of natural and man-made materials.

11.4.2.2.1.1 Carbon-14 dating (radiocarbon dating)

"Radiocarbon dating" (also referred to as "carbon dating" or "carbon-14 dating") is a method for determining the age of an object containing organic material by using the properties of radiocarbon $^{14}\mathrm{C}$, a radioactive isotope of carbon.

The method was developed by Willard Libby in the late 11940s (holocene calendar) and soon became a standard tool for archaeologists. Libby received the Nobel Prize for his work in 11960 (holocene calendar). The radiocarbon dating method is based on the fact that radiocarbon is constantly being generated in the atmosphere by the interaction of cosmic rays with atmospheric nitrogen. The resulting radiocarbon combines with atmospheric oxygen to form radioactive carbon dioxide, which is incorporated into plants by photosynthesis; animals then acquire $^{14}\mathrm{C}$ by eating the plants. When the animal or plant dies, it stops exchanging carbon with its environment, and from that point onwards the amount of $^{14}\mathrm{C}$ it contains begins to decrease as the $^{14}\mathrm{C}$ undergoes radioactive decay. Measuring the amount of $^{14}\mathrm{C}$ in a sample from a dead plant or animal such as piece of wood or a fragment of bone provides information that can be used to calculate when the animal or plant died. The older a sample is, the less $^{14}\mathrm{C}$ there is to be detected, and because the half-life of $^{14}\mathrm{C}$ (the period of time after which half of a given sample will have decayed) is about $5,730$ years, the oldest dates that can be reliably measured by radiocarbon dating are around $50,000$ years ago, although special preparation methods occasionally permit dating of older samples.

The idea behind radiocarbon dating is straightforward, but years of work were required to develop the technique to the point where accurate dates could be obtained. Research has been ongoing since the 11960s (holocene calendar) to determine what the proportion of $^{14}\mathrm{C}$ in the atmosphere has been over the past fifty thousand years. The resulting data, in the form of a calibration curve, is now used to convert a given measurement of radiocarbon in a sample into an estimate of the sample's calendar age. Other corrections must be made to account for the proportion of $^{14}\mathrm{C}$ in different types of organisms (fractionation), and the varying levels of $^{14}\mathrm{C}$ throughout the biosphere (reservoir effects). Additional complications come from the burning of fossil fuels such as coal and oil, and from the above-ground nuclear tests done in the 11950s (holocene calendar) and 11960s. Because the time it takes to convert biological materials to fossil fuels is substantially longer than the time it takes for its $^{14}\mathrm{C}$ to decay below detectable levels, they contain almost no $^{14}\mathrm{C}$, and as a result there was a noticeable drop in the proportion of $^{14}\mathrm{C}$ in the atmosphere beginning in the late 119th century (holocene calendar). Conversely, nuclear testing increased the amount of $^{14}\mathrm{C}$ in the atmosphere, which attained a maximum in

11963 (holocene calendar) of almost twice what it had been before the testing began.

Natural carbon has two stable isotopes: the ${}^{12}\mathrm{C}$ (98.892%) and ${}^{13}\mathrm{C}$ (1.108%). So there is no ${}^{14}\mathrm{C}$ in the natural carbon. The latter is produced in the upper atmosphere through the action of cosmic neutrons on the ${}^{13}\mathrm{C}$. We speak then of "neutron capture" (see further below) or "activation ${}^{13}\mathrm{C}(n,\gamma){}^{14}\mathrm{C}$" following:

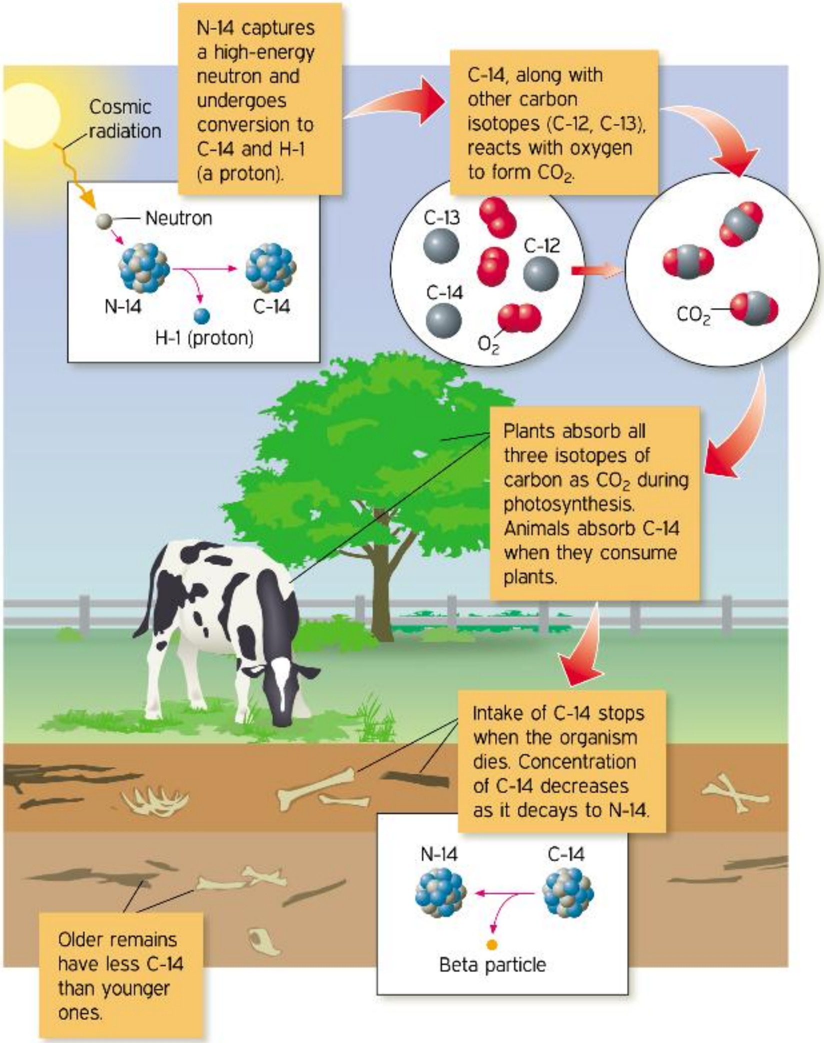
$$n+{}^{14}{}_{7}\mathrm{N}\rightarrow{}^{14}{}_{6}\mathrm{C}+p \tag{11.4.43}$$

where n represents a neutron and p represents a proton.

Thus, continuously ${}^{14}\mathrm{C}$ is produced in the upper atmosphere and decays naturally with a period of $5,730$ years. We easily imagine that the concentration in ${}^{14}\mathrm{C}$ is balanced when the production rate is equal to the disappearing rate due to radioactive decay process (otherwise they will no longer be any ${}^{14}\mathrm{C}$ everywhere today) following:

$${}^{14}{}_{6}\mathrm{C}\rightarrow{}^{14}{}_{7}\mathrm{N}+e^{-}+\bar{\nu}_e \tag{11.4.44}$$

By emitting a beta particle (an electron, e^{-}) and an electron antineutrino (ν_e), one of the neutrons in the ${}^{14}\mathrm{C}$ nucleus changes to a proton and the ${}^{14}\mathrm{C}$ nucleus reverts to the stable (non-radioactive) isotope ${}^{14}\mathrm{N}$.



N-14 captures a high-energy neutron and undergoes conversion to C-14 and H-1 (a proton).
Cosmic radiation
Neutron
N-14
C-14
H-1 (proton)
C-14, along with other carbon isotopes (C-12, C-13), reacts with oxygen to form CO₂.
C-13
C-12
C-14
O₂
CO₂
Plants absorb all three isotopes of carbon as CO₂ during photosynthesis. Animals absorb C-14 when they consume plants.
Intake of C-14 stops when the organism dies. Concentration of C-14 decreases as it decays to N-14.
N-14
C-14
Beta particle
Older remains have less C-14 than younger ones.

Figure 11.95: Idea behind Carbon dating (source: ?)

About 2.5 atoms of carbon ^{14}C are formed every second by square centimetre on the Earth's surface (this value is however dependent on many factors but with negligible variations over the very long term - you can find entire textbooks on this subject), the positive contribution to the number of atoms of ^{14}C is about:

$$\dot{N}_+ = 2.54\pi R^2 \cong 1.2\cdot 10^{19}\,[\text{atoms}\cdot\text{s}^{-1}] \qquad (11.4.45)$$

R being the Earth's radius.

Or in mass flow it represents:

$$\dot{m}_+ \cong 1.2\cdot 10^{19}\frac{14\,[\text{g}\cdot\text{mole}^{-1}]}{6.0221367\cdot 10^{23}\,[\text{atoms}\cdot\text{mole}^{-1}]} \cong 2.98\cdot 10^{-4}\,[\text{g}\cdot\text{s}^{-1}] \qquad (11.4.46)$$

The disintegration rate is supposed equal to the rate of radioactive production, that is to say:

$$-\dot{N}_+ = \dot{N}_- = -1.28\cdot 10^{19}\,[\text{atoms}\cdot\text{s}^{-1}] \qquad (11.4.47)$$

As the global quantity:

$$\frac{\mathrm{d}(\dot{N}_+ + \dot{N}_-)}{\mathrm{d}t} = \frac{\mathrm{d}N}{\mathrm{d}t} \cong 0 \qquad (11.4.48)$$

As the disintegration rate is equal to:

$$A = \dot{N}_- = -\lambda N = \frac{-\ln(2)}{5700\cdot 365.256\cdot 24\cdot 60\cdot 60}\cdot N = -1.28\cdot 10^{19}\,[\text{atoms}\cdot\text{s}^{-1}] \qquad (11.4.49)$$

We conclude that there are $N \cong 3.32\cdot 10^{30}$ atoms of ^{14}C. The reader can calculate by multiplying by the mass value of the ^{14}C atom ($2.34\cdot 10^{-26}$ [kg]) that it makes quite a significant mass in the atmosphere.

As we already said it, this radioisotope is found in the chemical form CO_2 and penetrates through photosynthesis and metabolism in plants and animals. On the death of the plant or animal, the quantity of ^{14}C freezes and starts to decrease through radioactive decay over the ages:

$$^{14}\text{C} + {}^{12}\text{C} = N = c^{te} \qquad (11.4.50)$$

Radiocarbon dating is therefore a simple comparison between the concentration in ^{14}C of living matter and dead matter of two same objects/living entity. In fact, we determine the specific activities:

$$(A_{^{14}\text{C}})_{\text{Death entity}} \cong (A_{^{14}\text{C}})_{\text{Living entity}}\, e^{-\lambda(t-t_0)} \qquad (11.4.51)$$

where for objects "living entity" can be translate in "nowadays comparable element".

That is to say the "radiocarbon age" is given by:

$$t \cong -\frac{1}{\lambda}\ln\left(\frac{(A_{^{14}\text{C}})_{\text{Death entity}}}{(A_{^{14}\text{C}})_{\text{Living entity}}}\right) = -\frac{T_{1/2}}{\ln(2)}\ln\left(\frac{(A_{^{14}\text{C}})_{\text{Death entity}}}{(A_{^{14}\text{C}})_{\text{Living entity}}}\right) \qquad (11.4.52)$$

with for ^{14}C:

$$\frac{T_{1/2}}{\ln(2)} \cong 8267 \tag{11.4.53}$$

Therefore the latter relation is often written:

$$t \cong -8267 \ln\left(\frac{(A_{^{14}\text{C}})_{\text{Death entity}}}{(A_{^{14}\text{C}})_{\text{Living entity}}}\right) = 8267 \ln\left(\frac{(A_{^{14}\text{C}})_{\text{Living entity}}}{(A_{^{14}\text{C}})_{\text{Death entity}}}\right) \tag{11.4.54}$$

and even more shortly:

$$\boxed{t \cong 8267 \ln\left(\frac{A_0}{A}\right) = 8267 \ln\left(\frac{\lambda N_0}{\lambda N}\right) = 8267 \ln\left(\frac{N_0}{N}\right) = 8267 \ln\left(F_m\right)} \tag{11.4.55}$$

where F_m is the mass fraction notation.

Remark

Measurement of radiocarbon was originally done by beta-counting devices, which counted the amount of beta radiation emitted by decaying ^{14}C atoms in a sample. More recently, accelerator mass spectrometry has become the method of choice; it counts all the ^{14}C atoms in the sample and not just the few that happen to decay during the measurements; it can therefore be used with much smaller samples (as small as individual plant seeds), and gives results much more quickly.

The reader must keep in mind that three hypothesis (assumptions) have been implicitly done for the calculations above:

H1. The amounts of parent and daughter isotopes at the beginning, when the rock formed, must be known (the initial conditions) or their uncertainty impact on the resulting calculations results.

H2. All daughter atoms measured today must only have been derived by in situ radioactive decay of parent atoms (a closed system) in the opposite case the external sources must be taken into account in the uncertainty value of the resulting calculations results.

H3. The radioisotope decay rates are constant and if not the variations must be taken into account in the uncertainty value of the resulting calculations results.

Remark

The oldest dated rocks on Earth, as an aggregate of minerals that have not been subsequently broken down by erosion or melted, are more than 4 billion years old, formed during the Hadean Eon of Earth's geological history. Such rocks are exposed on the Earth's surface in very few places (some meteorites, such as the ALH84001 Mars meteorite found in the Allan Hills of Antarctica, are older but they were not formed on Earth). Some of the oldest surface rock can be found in the Canadian Shield, Australia, Africa and in a few other old regions around the world. The ages of these felsic rocks are generally between 2.5 and 3.8 billion years. The approximate ages have a margin of error of millions of years. In 11999 (holocene calendar), the oldest known rock on Earth was dated to 4.031 ± 0.003 billion years, and is part of the Acasta Gneiss of the Slave craton in northwestern Canada.

There are a lot of complementary (for double, triple checks) dating methods:

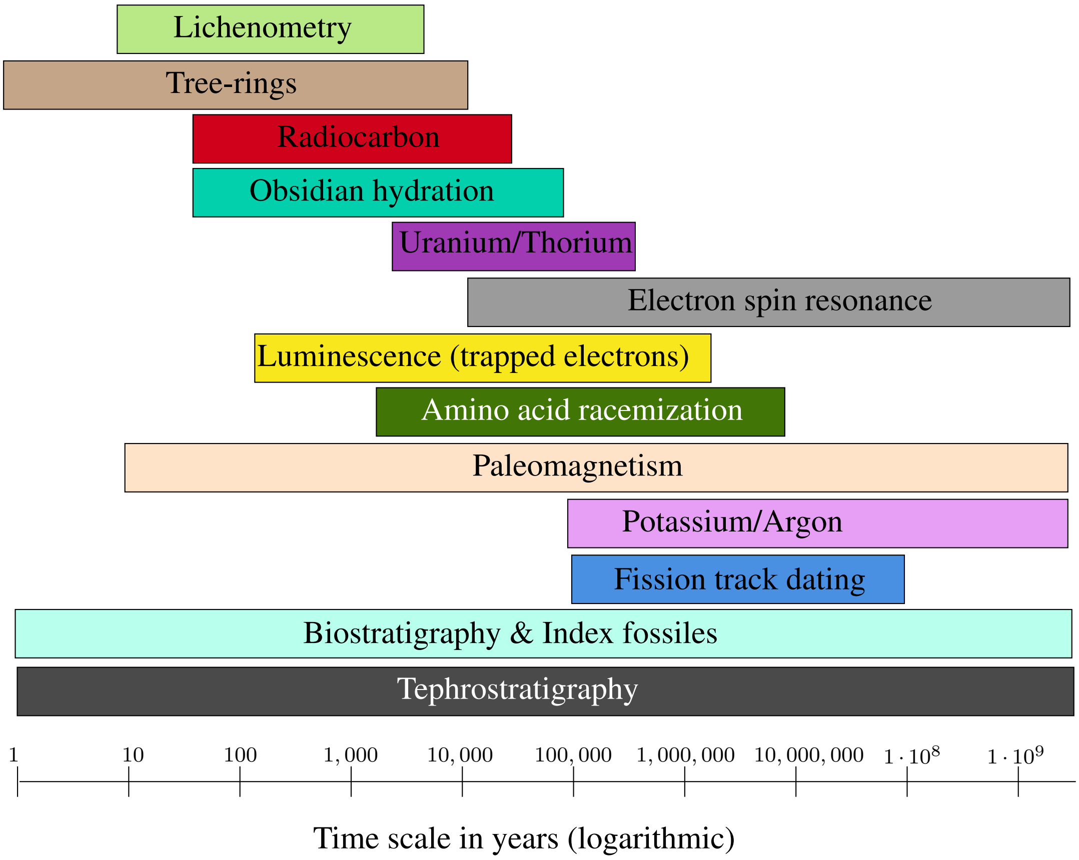


Figure 11.96: **Most common types of radiometric dating methods**

Some of them are also used because the accuracy of the others are not high enough with our 121st century (holocene calendar) instruments when the sample is too old.

Caution!!!! A common urban legend is that the older is a sample, the less accurate is its radioactive dating. In reality this an inaccurate statement formulated as previously. It should be instead formulated as following: the older is a given sample characterized by all its properties, the less accurate is its dating based on a single dating method (scientists switch to different dating method based on the age of a sample). For example Lucy bones were dated with an age of 3.18 million years old with a margin error of $\pm 30,000$ years (hence a margin error of 0.94%), and the oldest stones on Earth (see below for the details) were dated 4.295 billions years with a margin of 0.015 billions years, hence a margin error of 0.348% (less than the error margin of Lucy!!!).

Electron spin resonance (ESR), is also named "electron paramagnetic resonance" (EPR), may be grouped together with thermoluminescence (TL) and optically stimulated luminescence (OSL) as trapped charge dating methods (for a very good paper on ESR, see [218]).

A common technical accuracy limit for Carbon dating in this beginning of the 121st century (holocene calendar) is still $40,000$ years. Indeed, as the half life of Carbon-14 is about $5,700$ years, therefore with $40,000$ years there is under 1% of the original Carbon-14 left (0.79% to be exact), and it becomes too hard to measure it accurately. Stuff supposed to be very old like diamonds - a few hundred of millions of years old or greater - that are made only of carbon there is no trace of Carbon-14 left (see [529]).

Remark

As we will see in the section of Cosmology, looking far in space is equivalent at looking in the past (because light takes time to travel from one place to another, we see objects not as they are now but as they were at the time when they released the light that has travelled across the universe to us). Therefore modern telescopes are like time machines as we can go back as 13 billion years in the past by spectral observation. Thanks to spectroscopy we can check hydrogen spectral series that directly depends on the fine-structure constant (see page 4655) - as for the relation of activity decay that we have derived during our study of the tunnel effect (see page 4840) that depends only in constant parameters involved in the fine-structure constant - and see if the latter has changed these last 13 billion years. Experimental evidence as presented in [574] find a spatial variation of the order of $\sim 10^{-5}$ is preferred over a no-variation model at the 3.9σ level:

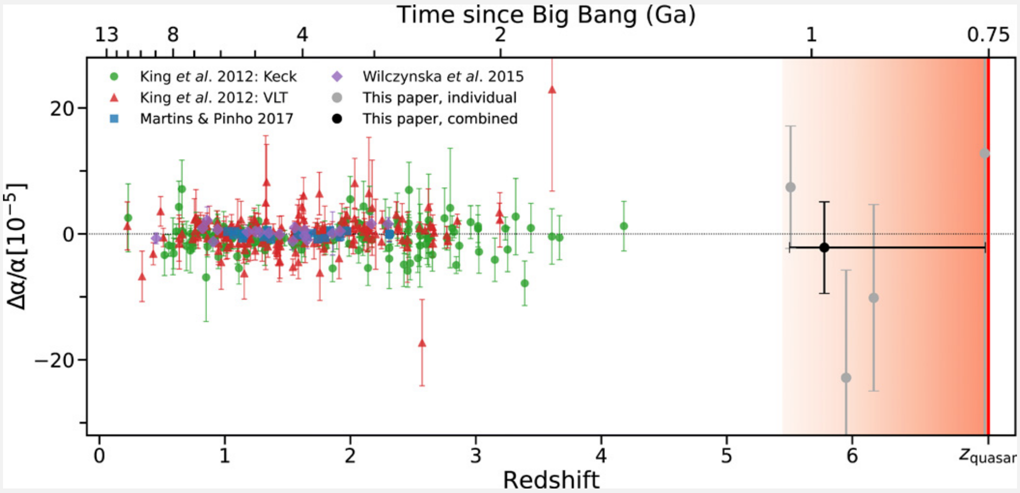

Figure 11.97: **Direct measurements of $\Delta\alpha/\alpha$, taken from quasar absorption measurements**

This variation of $\sim 10^{-5}$ of the fine-structure constant would lead in a relative variation in the radioactivity decay of the order of $\sim 10^{-4}$. That means on a datation of something of 1 billion year old, the error is approximately of $100,000$ years.

11.4.2.2.1.2 Rubidium-87 dating (meteorites dating/isochron dating)

Radioactive decay has become one of the most useful methods for determining the age of formation of rocks. However, in the very principal of radiometric dating there are several vital assumptions that have to be made in order for the age to be considered valid. These assumptions include for recall:

- The process must be irreversible[34]
- The laws and constants of physics didn't change during the considerated range time
- The initial amount of the daughter isotope is known
- Neither parent or daughter product has migrated into, or out of, the closed rock system[35]
- Decay has occurred at a constant rate over time.

But what if one or some combination of these assumptions is incorrect? Then the computed age based on the accumulation of daughter products will be obviously incorrect. In order to use the valuable information provided by radiometric dating, a new method had to be created that would determine a quite accurate date and validate the assumptions of radiometric dating. For this purpose, "isochron dating" was developed, a process that solves quite well the initial amount of the daughter isotope issue.

The clock most suitable for meteorites is the decay of Rubidium ($^{87}\mathrm{Rb}$) into Strontium ($^{87}\mathrm{Sr}$): which has a half-life of about 49 billion years. The manner in which the age is determined is based on calculating ratios of these isotopes, as the following calculation will show:

We know if there is some $^{87}\mathrm{Rb}$ present in the meteorite, that there will also be the decay product $^{87}\mathrm{Sr}$. However there will also be some unknown amount of $^{87}\mathrm{Sr}$ that was in the meteorite when it formed. We can state mathematically, that the amount of $^{87}\mathrm{Sr}$ present now, must have come from the amount that was there originally, plus any decay product from $^{87}\mathrm{Rb}$:

$$^{87}\mathrm{Sr}_{\text{now}}={}^{87}\mathrm{Sr}_{\text{original}}+\left({}^{87}\mathrm{Rb}_{\text{original}}-{}^{87}\mathrm{Rb}_{\text{now}}\right) \tag{11.4.56}$$

The term in parenthesis, the amount of $^{87}\mathrm{Rb}$ that decayed into $^{87}\mathrm{Sr}$ can be related by the radioactive decay law:

$$^{87}\mathrm{Rb}_{\text{original}}={}^{87}\mathrm{Rb}_{\text{now}}e^{\lambda t} \tag{11.4.57}$$

where as usual γ is the rate of radioactive decay, and t is the elapsed time.

By substituting that in the original equation we get:

$$^{87}\mathrm{Sr}_{\text{now}}={}^{87}\mathrm{Sr}_{\text{original}}+{}^{87}\mathrm{Rb}_{\text{now}}\left(e^{\gamma t}-1\right) \tag{11.4.58}$$

---

[34] Isotope dating satisfies this requirement, as daughter products do not decay back to the original parent element

[35] That "diffusion issue" is solved by taking multiple samples in a studied object - near the surface, in the middle and in-between multiples times - an incorporating the results in the classical statistical confidence interval that is always provided with isotopic dating! And repeating the process of multiple object found in the same area.

Along with $^{87}\mathrm{Sr}$, $^{86}\mathrm{Sr}$ also occurs in meteorites, but it is not a decay product and its amount does not change over time: so we can divide this constant in the above equation without changing the equality:

$$\frac{^{87}\mathrm{Sr}_{\text{now}}}{^{86}\mathrm{Sr}}=\frac{^{87}\mathrm{Sr}_{\text{original}}}{^{86}\mathrm{Sr}}+\frac{^{87}\mathrm{Rb}_{\text{now}}}{^{86}\mathrm{Sr}}\left(e^{\lambda t}-1\right) \tag{11.4.59}$$

Technically in the geochronology field is denoted:

$$\boxed{\frac{D}{D_i}=\frac{D_0}{D_i}+\frac{P}{D_i}\left(e^{\lambda t}-1\right)} \tag{11.4.60}$$

Note that this is the equation of a line in the form:

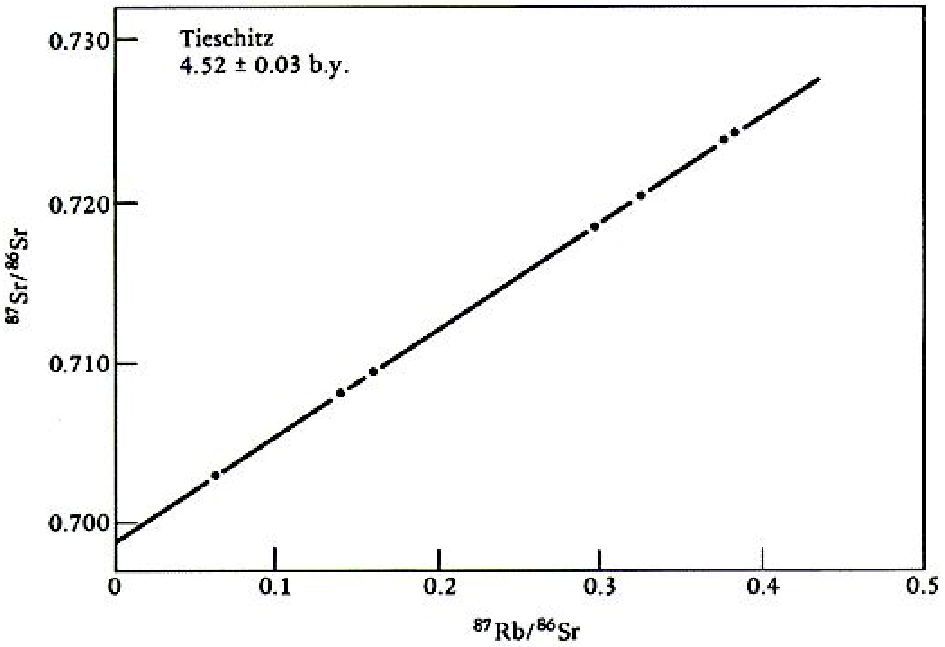
$$y=ax+b \tag{11.4.61}$$

where, a, the slope, is $(e^{\gamma t}-1)$ and b, the y intercept, is the original strontium isotope ratio.

And then we get straightforward:

$$t_a=\frac{1}{\lambda}\ln(a+1) \tag{11.4.62}$$

Two of these quantities can be measured: $\frac{^{87}\mathrm{Sr}_{\text{now}}}{^{86}\mathrm{Sr}}$ and $\frac{^{87}\mathrm{Rb}_{\text{now}}}{^{86}\mathrm{Sr}}$. By taking samples from various parts of a meteorite and plotting these results: the data will fall on a straight line whose slope characterizes the age of the meteorite. Theses lines are named "isochrons", an example for the meteorite Tieschitz (fall: 11878 - according to holocene calendar - Czechoslovakia) is shown in the following figure (from McSween):



Precise measurement of radioactive isotopes provides a way to determine the age of a meteorite. In the method illustrated here, a radioactive isotope of rubidium (^{87}Rb) decays to a stable isotope of strontium (^{87}Sr), which mixes with already existing strontium isotopes (^{87}Sr and ^{86}Sr). The individual data points in this diagram represent minerals separated from the Tieschitz (Czechoslovakia) chondrite. The age of the meteorite (4.52 billion years) is calculated from the slope of the diagonal line, which steepens with increasing time.

So the trick to the isochron diagram is the normalization of both parent and daughter isotope to a third isotope. This third isotope is the non-decay product isotope of the same element as the daughter element. In the initial state, the graph of daughter isotope to the third isotope versus parent isotope to the third isotope should result in a straight, horizontal line.

The process of evaluating the daughter product as a ratio against another isotope of the same element is a quite valid method because, when a mineral or rock forms from a homogeneous state, the elements that are assimilated into crystalline formation are very restricted. The key to the formation of crystals in the rock is that the process is selective between elements, but is indifferent to isotopes of the same element. Thus, the daughter product and any other isotopes of the same element will be incorporated into the minerals of a rock with the same ratio. This initial ratio allows the non-daughter product isotope to be representative of the initial amount of the daughter product. This assumes there has been no migration of daughter or parent nuclei within the matrix since its solidification. It also assumes that the daughter isotopes had sufficient time to uniformly distribute themselves throughout the material matrix; i.e., crystallization cannot be too rapid.

As time progresses and decay occurs, the number of atoms of the parent isotope decreases, and the number of atoms of the daughter isotope increases accordingly. The amount of non-decay isotope in the sample does not change. Thus, as decay occurs, the parent ratio decreases and the daughter ratio increases.

The features of the isochron method provide a way do reduce doubt and speculation about an age that is computed using these methods. Based on the assumptions of basic radioactive dating, the problem of an unknown initial amount of daughter isotope is eliminated by the definition of the isochron itself. The problem of contamination is "self-checking". If contamination has occurred within a sample, the ratios from the sample shouldn't fall on a line. Instead, the points would be in a scatter on the graph. Points that do not fall on a straight line suggest contamination, and this invalidates the results. However, by this same principle, points falling relatively close to a best fit line should provide an accurate date for the age of the rock being dated.

All the different radiometric dating methods have provided successful scientifically peer review independent evidence (with control group) that:

- Young Earth belief according to the Genesis of the Abrahamic religion is wrong.
- The Shroud of Turin (see [123]) is a fake relic like most relics of the catholic church (the fact that the shroud of Turn is a fake relic is also confirmed by historical analysis [478]).
- The oldest Hominids is dated from approximately 4.2 million years ago (fact that goes against all religions beliefs worldwide)
- etc...

Exposure of the metamorphosed rocks of the Nuvvuagittuq Greenstone Belt (NGB) from the Porpoise Cove locality, Quebec, Canada. Some of these rocks have an Uranium (U)/Lead (Pb) dating of minimum 3.77 billions years (see [90] and [425]) and a Samarium (Sm)/Neodymium (Nd) age between 4.28 and 4.31 billion years (see [425] and [426]) and may be the oldest rocks on Earth.

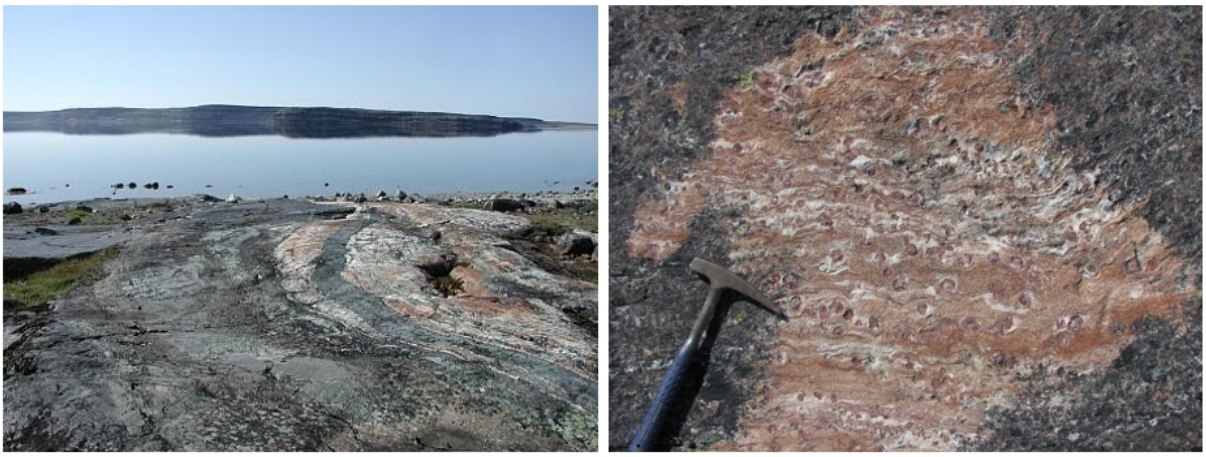


Figure 11.98: **Exposure of the metamorphosed rocks of the Nuvvuagittuq Greenstone Belt (source: left NASA, right Jonathan O'Neil)**

Researchers have determined (see [153]) that fossilized evidence of bacteria from ancient seafloor hydrothermal vent precipitates found in the Nuvvuagittuq belt in Quebec, Canada is dated with Uranumium (U)-Lead (Pb) at least 3.77 billion years old (or even as much as 4.28 billion years old). The minimum age of the fossils would make them the oldest indication of life on Earth so far.

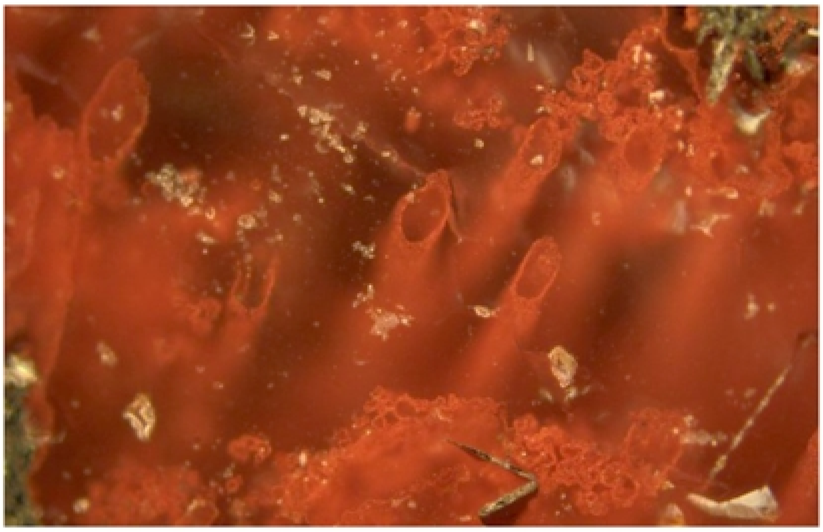

Figure 11.99: Hematite tubes from microfossils dating back to 3.770 **billion years (source: [153])**

Again and as always, Science helps to highlight the lies of all religions.

For more details and techniques about Radiometric dating, the reader can refer the to excellent following textbook [210].

11.4.2.2.1.3 Young Earth heat problem

One of the issues in the creation/evolution debate is the claim, in a few thousands of religions among the dozens of thousands of existing one, that radioactive decay is not constant. In order for the Earth to appear old[36], the creationists of these religions must assume that radioactive decay rates in the past were faster. This solves the problems of old ages in rocks, but unfortunately opens up a bigger problem. Radioactive decay gives off heat. The amount of heat generated is proportional to the rate of decay and the amount of radioactive material present at the time. In the following exercise, I show how much heat can be generated by radioactive decay if decay rates were faster in the past. Please note that the following analysis uses present-day heat production values which are observable quantities and I have also assumed (in the creationist analysis) that each of the elements has the same rate of decay. Changing the decay rates to those observed today for each of the major heat producing elements makes the mathematics a bit more tedious, but does not significantly alter the conclusions given here.

Present day of heat production from radioactive decay in the Earth is produced mainly by the isotopes ^{238}U, ^{235}U, ^{232}Th and ^{40}K and has a value of $6.18\cdot 10^{-12}\;[\text{W}\cdot\text{kg}^{-1}]$ ([546]). If the heat flow out of the Earth were due solely to radioactive decay in the mantle and crust, it would equal Heat Production · (Mass of Mantle + Crust), i.e.:

$$Q=6.18\cdot 10^{-12}\;[\text{W}\cdot\text{kg}^{-1}]\cdot 4.0\cdot 10^{24}\;[\text{kg}]\cong 2.47\cdot 10^{13}\;[\text{W}] \tag{11.4.63}$$

The heat flow out of the Earth can be calculated from Fourier's Law of heat conduction (see section Thermodynamics page 3684):

$$\Phi_q=\kappa\frac{\mathrm{d}T}{\mathrm{d}z} \tag{11.4.64}$$

where k is the thermal conductivity of the rocks in $[\text{W}\cdot\text{m}^{-1}\cdot{}^\circ\text{C}^{-1}]$, $\mathrm{d}T/\mathrm{d}z$ is the geothermal gradient (change in temp with depth) in $[^\circ\text{C}\cdot\text{m}^{-1}]$ and obviously Φ_q is in $[\text{W}\cdot\text{m}^{-2}]$.

To calculate the surface heat flow, we divide the result of:

$$Q=6.18\cdot 10^{-12}\;[\text{W}\cdot\text{kg}^{-1}]\cdot 4.0\cdot 10^{24}\;[\text{kg}]\cong 2.47\cdot 10^{13}\;[\text{W}] \tag{11.4.65}$$

by the total surface area of the earth ($\cong 5.1\cdot 10^{14}\;[\text{m}^2]$), we get:

$$\Phi_q=\frac{2.47\cdot 10^{13}\;[\text{W}]}{5.1\cdot 10^{14}\;[\text{m}^2]}\cong 0.048\;[\text{W}\cdot\text{m}^{-2}] \tag{11.4.66}$$

If we now use this to calculate the temperature-depth profile $\mathrm{d}T/\mathrm{d}z$, we need to use an average value of thermal conductivity. We use $3.00\;[\text{W}\cdot\text{m}^{-1}\cdot{}^\circ\text{C}^{-1}]$ as an average thermal conductivity of the rocks. This yields:

$$\frac{\mathrm{d}T}{\mathrm{d}z}\cong\frac{0.048\;[\text{W}\cdot\text{m}^3]}{3\;[\text{W}\cdot\text{m}^{-1}\cdot{}^\circ\text{C}^{-1}]}\cong 16\;[^\circ\text{C}\cdot\text{km}^{-1}] \tag{11.4.67}$$

Thus, for every 1 kilometer depth, the temperature will increase by about $16\;[^\circ\text{C}]$. Obviously as we get deeper into the crust and mantle, temperature increases are not linear because they are a function of pressure and other factors. Nevertheless, this relationship is useful to depths of $30-70$ kilometers. Therefore, at a depth of 10 kilometers, the temperature would be about $160\,[^\circ\text{C}]$. Basaltic rock melts at about $1200\,[^\circ\text{C}]$. There are some simplifications made in the above calculations since much of the heat production $(\sim 67\%)$ is confined to the crust, but the illustration below is useful regardless of this simplification.

---

[36] Bigots think that the only evidence of an old Earth is radioactivity but scientist have multiple evidence that the Earth is much older than 6,000 years old: radioactivity, stratigraphy, archaeology, palaeontology, thermodynamics, astrophysics, geology, astronomy, dendrochronology, linguistic, crystallography

Let's look at these same relationships with a much younger Earth and a faster rate of decay. In our example, we will use a quite standard creationist age (in the christian faith) for the Earth of $6,000$ years. In order to carry out the analysis, we must still assume some sort of decay constant. There are a number of ways this could be done, but the simplest is to assign an average half-life. We will use 500 years as the average half life for the radioactive elements listed above. In reality, we are being overly generous to the young Earth crowd. If rates were variable, they would probably have been much faster than this and the resultant earth conditions would be more extreme. The interested reader can easily play with the variables on a spreadsheet and see how they affect the conclusions reached below.

Remark

It is possible, though more tedious to calculate the heat release using a decelerating decay rate. It does not change the basic conclusion reached in the following developments. In order to do this, one simply replaces λ with a function $e^{-\text{rate}}$.

In order to figure out the rate of heat production in the past, we must first calculate a decay constant λ. This is calculated from (see section Nuclear Physics page 5030):

$$T_{1/2}=\frac{\ln(2)}{\lambda} \qquad (11.4.68)$$

or:

$$\lambda=\frac{\ln(2)}{T_{1/2}} \qquad (11.4.69)$$

using 500 years for $T_{1/2}$, we get $\lambda=1.38\cdot 10^{-3}\,[\text{s}^{-1}]$.

The rate of heat production at any time in the past is given by the following formula (see section Nuclear Physics page 5029):

$$H_{\text{past}}=H_{\text{present}}\cdot e^{\lambda(t-t_0)} \qquad (11.4.70)$$

we use $H_{\text{present}}=6.18\cdot 10^{-12}\,[\text{W}\cdot\text{kg}^{-1}]$ and $t-t_0=6,000$ years and λ as calculated above and we get:

$$H_{\text{past}}=2.43\cdot 10^{-8}\,[\text{W}\cdot\text{kg}^{-1}] \qquad (11.4.71)$$

We can now use this value to calculate the amount of heat flow out of the Earth due solely to this ancient ($6,000$ year old...) heat production and calculate a thermal profile as we did above using first:

$$H_{\text{past}}\cdot(\text{Mass of Mantle}+\text{crust})=\text{total heat production}$$

Hence:

$$H_{\text{past}}=2.43\cdot 10^{-8}\,[\text{W}\cdot\text{kg}^{-1}]\cdot 4.0\cdot 10^{24}\,[\text{kg}]\cong 9.75\cdot 10^{16}\,[\text{W}] \qquad (11.4.72)$$

We now divide this value by the surface area of the Earth to get the heat flow Q at $6,000$ years ago:

$$\Phi_q=\dfrac{9.75\cdot 10^{16}\,[\text{W}]}{5.1\cdot 10^{14}\,[\text{m}^2]}\cong 191\,[\text{W}\cdot\text{m}^{-2}] \tag{11.4.73}$$

Using the same value for thermal conductivity $3.00\,[\text{W}\cdot\text{m}^{-1}\cdot{}^\circ\text{C}]$, we can calculate the $\mathrm{d}T/\mathrm{d}z$ profile as earlier above in:

$$\dfrac{\mathrm{d}T}{\mathrm{d}z}=\dfrac{191\,[\text{W}\cdot\text{m}^{-2}]}{3.00\,[\text{W}\cdot\text{m}^{-1}\cdot{}^\circ\text{C}^{-1}]}\cong 65,000\,[{}^\circ\text{C}\cdot\text{km}^{-1}] \tag{11.4.74}$$

At $6,000$ years ago, it is pretty obvious that the entire Earth would be molten and Adam and Eve's goose was cooked. We are not implying that this is a purely conductive regime. What we are showing is that the thermal regime on a $6,000$ year old Earth with rampant radioactive decay is extreme. If you want to turn off the engine and let the Earth cool from this extreme you also run into time spans much greater than $6,000$ years because it will take a while to cool down from those extreme temperatures. It's difficult to estimate how long it would take for the Earth to reach present-day temperatures... It is clear that rapid decay results in a tremendous release of heat. We suppose some could always argue that the Earth has been cooling since this initial heating and that there is no further significant heat released by radioactive decay. In that case, the cooling of the Earth reduces to the Kelvin problem and gives an age of 20-60 million years (and 2000 thousand years ago the geothermal gradient would have been around $\sim 400\,[{}^\circ\text{C}\cdot\text{km}^{-1}]$).

11.4.2.2.2 Radioactive Decay chain

Definition (#11.4.513): A "decay chain" refers to the radioactive decay of different discrete radioactive decay products as a chained series of transformations. They are also known as "radioactive cascades". Most radioisotopes do not decay directly to a stable state, but rather undergo a series of decays until eventually a stable isotope is reached.

Caution!!!! Not only nucleus of atoms decays. But also most particles and even some fundamental particles (yes! but they are not made of the stuff they decay of as experience show us with the τ fundamental particle that has at least 30 different decay chains). However some particles don't decay (as far as we know) like: the photon, the electron (anti-electron), the lightest neutrino (and its anti-particle[a] and (presumed) the graviton.

---

[a] Half-integer spin particles have well-defined antiparticles, integer spin particles exhibit this fascinating self-duality.

Decay stages are referred to by their relationship to previous or subsequent stages. A "parent isotope " is one that undergoes decay to form a "daughter isotope". One example of this is uranium (atomic number 92) decaying into thorium (atomic number 90). The daughter isotope may be stable or it may decay to form a daughter isotope of its own. The daughter of a daughter isotope is sometimes named a "granddaughter isotope".

In general we denote a radioactive cascade by:

$$\mathrm{X}_1^* \rightarrow \mathrm{X}_2^* \rightarrow \mathrm{X}_3^* \rightarrow \ldots \mathrm{X}_n \tag{11.4.75}$$

where the small symbol * denotes a given radioactive isotope, X_n being the final stable isotope of the radioactive of the mother element X_1^* (the elements between all being unstable nuclides).

11.4.2.3 Two level radioactive cascade

Let us consider the two nuclide situation (we will not focus on higher order level excepted on request of many readers).

Let us suppose that at the beginning of time, the first descendant exists only negligible quantity such that we have for initial conditions (IC) at $t=0$:

$$\begin{aligned} N_1(t=0)&=N_{1_0}\\ N_2(t=0)&=0 \end{aligned} \tag{11.4.76}$$

The variation of the parent nuclide (1) is given by a negative contribution: the disintegration of (1).

We have:

$$\mathrm{d}N_1=-\lambda_1 N_1 \mathrm{d}t \tag{11.4.77}$$

having for solution taking into account the initial conditions:

$$N_1(t)=N_{1_0}e^{-\lambda_1 t} \tag{11.4.78}$$

The variation of the descendant member (2), that is to say the daughter of (1), is given by a positive contribution (the atoms of (1) disintegrated) and one negative, the disintegration of (2). Then:

$$\mathrm{d}N_2=+\lambda_1 N_1\mathrm{d}t-\lambda_2 N_2 \mathrm{d}t \Rightarrow \frac{\mathrm{d}N_2}{\mathrm{d}t}+\lambda_2 N_2=+\lambda_1 N_1=\lambda_1 N_{1_0}e^{-\lambda_1 t} \tag{11.4.79}$$

So we have to solve this differential equation (see section Differential and Integral Calculus page 1609.

We have for homogeneous solution (characteristic equation):

$$\frac{\mathrm{d}N_2}{\mathrm{d}t}+\lambda_2 N_2=0 \tag{11.4.80}$$

We derive from the homogeneous equation the special (homogeneous) solution:

$$N_2^h(t)=N_{2_0}^h e^{-\lambda_2 t} \tag{11.4.81}$$

with the letter h to signify that this is the "homogeneous" solution.

Let us now determine the particular solution of:

$$\frac{\mathrm{d}N_2}{\mathrm{d}t}+\lambda_2 N_2=\lambda_1 N_{1_0}e^{-\lambda_1 t} \tag{11.4.82}$$

The idea to solve this is to put:

$$N_2^p(t)=N_{2_0}^p e^{-\lambda_p t} \tag{11.4.83}$$

with the letter p for "particular" (implicitly: "special solution"). Substituting we find:

$$-\lambda_p\left(N_{2_0}^p e^{-\lambda_p t}\right)+\lambda_2\left(N_{2_0}^p e^{-\lambda_p t}\right)=(\lambda_2-\lambda_p)N_{2_0}^p e^{-\lambda_p t}=\lambda_1\left(N_{1_0}e^{-\lambda_1 t}\right) \tag{11.4.84}$$

Therefore we must have:

$$\Rightarrow \lambda_p=\lambda_1 \tag{11.4.85}$$

because otherwise if we had $\lambda_p=\lambda_2$ we would have a zero equality which is absurd. Therefore getting rid of the exponential we get:

$$-\lambda_1 N_{2_0}^p+\lambda_2 N_{2_0}^p=\lambda_1 N_{1_0} \tag{11.4.86}$$

from which we derive that:

$$N_{2_0}^p=\frac{\lambda_1 N_{1_0}}{\lambda_2-\lambda_1} \tag{11.4.87}$$

Finally the general solution is the sum of the homogeneous solution and the particular one, therefore:

$$N_2(t)=N_{2_0}^h e^{-\lambda_2 t}+\frac{\lambda_1 N_{1_0}}{\lambda_2-\lambda_1}e^{-\lambda_1 t} \tag{11.4.88}$$

Let us apply the initial conditions:

$$t=0 \qquad N_2(t=0)=0\Rightarrow N_{2_0}^h=\frac{-\lambda_1 N_{1_0}}{\lambda_2-\lambda_1} \tag{11.4.89}$$

Finally we have:

$$\boxed{N_2(t)=\frac{\lambda_1 N_{1_0}}{\lambda_2-\lambda_1}\left(e^{\lambda_1 t}-e^{-\lambda_2 t}\right)} \tag{11.4.90}$$

In geology and archaeology the latter is often rearrange and denoted:

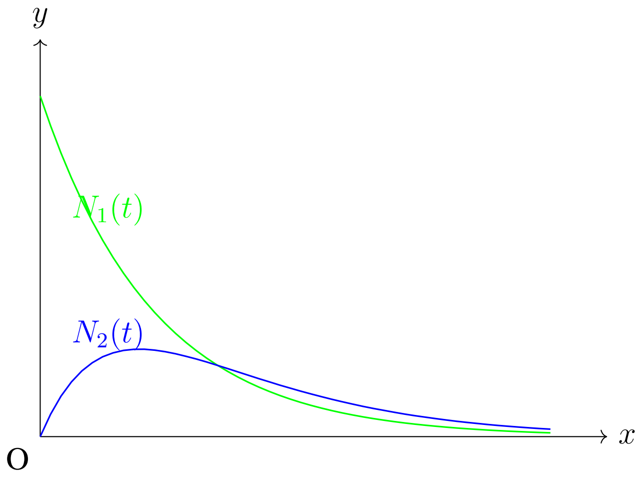
$$t=\frac{\ln\left(1-\dfrac{N_2(t)}{N_{1_0}}\dfrac{\lambda_2-\lambda_1}{\lambda_1}\right)}{\lambda_2-\lambda_1} \tag{11.4.91}$$

as all the parameters in the right hand side of the equality can be determined in a laboratory nowadays with less than tenth of thousand of percent, we can then determine age of rocks (and of many other stuffs).

If we plot:

$$\begin{aligned}N_1(t)&=N_{1_0}e^{-\lambda_1 t}\\N_2(t)&=\frac{\lambda_1 N_{1_0}}{\lambda_2-\lambda_1}\left(e^{\lambda_1 t}-e^{-\lambda_2 t}\right)\end{aligned} \tag{11.4.92}$$

we get:



$N_2(t)$ being zero for $t=0$ and for $t=+\infty$, it must pass, as the for activity $A_2(t)$, through a maximum. Given t^* the time when the maximum is observed, we have:

$$\begin{aligned}&\left.\dfrac{\mathrm{d}A_2}{\mathrm{d}t}\right|_{t=t^*}=\left.\dfrac{\mathrm{d}(\lambda_2 N_2)}{\mathrm{d}t}\right|_{t=t^*}=0=\lambda_2\dfrac{\lambda_1 N_{1_0}}{\lambda_2-\lambda_1}\left(-\lambda_1 e^{-\lambda_1 t^*}+\lambda_2 e^{-\lambda_2 t^*}\right)\\&\Rightarrow\left(-\lambda_1 e^{-\lambda_1 t^*}+\lambda_2 e^{-\lambda_2 t^*}\right)=0\end{aligned}\tag{11.4.93}$$

from where:

$$t^*=\dfrac{\ln\left(\dfrac{\lambda_1}{\lambda_2}\right)}{\lambda_1-\lambda_2}\tag{11.4.94}$$

The knowledge of t^* is important especially in nuclear medicine where we want to administer the product 1 for radio-diagnostic purposes and minimize adverse effects of the daughter(s) element(s) of 1. We then choose elements such that the time t^* is greater than the biological elimination time (body's natural elimination pathways) of its daughter(s) elements(s). We will return on this subject in a few paragraphs after studying three typical scenarios of radioactive filiation:

11.4.2.3.1 Secular equilibrium

This type of relation between mother and daughter activities occurs when the mother nucleus half-life is much greater than that of the daughter nucleus half-life. In other words, the radioactive decay of the mother nucleus is negligible and the activity of the descendent tends toward that of the parent.

We then have in this particular case:

$$\lambda_1\ll\lambda_2\tag{11.4.95}$$

So we have for the activity using the previously proved relation:

$$\begin{aligned}\lambda_2 N_2(t)=A_2(t)&=\dfrac{\lambda_2\lambda_1 N_{1_0}}{\lambda_2-\lambda_1}\left(e^{-\lambda_1 t}-e^{-\lambda_2 t}\right)=\dfrac{\lambda_2}{\lambda_2-\lambda_1}\left(e^{-\lambda_1 t}-e^{-\lambda_2 t}\right)\\&\underset{\lambda_1\ll\lambda_2}{=}A_{1_0}\left(e^{-\lambda_1 t}-e^{-\lambda_2 t}\right)\end{aligned}\tag{11.4.96}$$

Therefore:

$$A_2(t) = A_{1_0}\left(e^{-\lambda_1 t} - e^{-\lambda_2 t}\right) \tag{11.4.97}$$

We also see that in the case where $\lambda_1 \ll \lambda_2$ and $t \to +\infty$, we have:

$$\boxed{A_2(t) = A_{1_0}\left(e^{-\lambda_1 t} - e^{-\lambda_2 t}\right) \cong A_{1_0} e^{-\lambda_1 t} = A_1(t)} \tag{11.4.98}$$

in other words, the mother and daughter activities, become equivalent after a large enough time. For example, after a period of a half-life of the daughter isotope, we already have the daughter activity that is 50% that of the parent activity:

$$A_2(T_{1/2}) \cong A_{1_0} e^{-\lambda_1 T_{1/2}} = \frac{1}{2} A_{1_0} \tag{11.4.99}$$

If we have the case where the following approximation is acceptable:

$$\lambda_1 \cong 0 \tag{11.4.100}$$

we will have:

$$A_2(t) \cong A_{1_0}\left(1 - e^{-\lambda_2 t}\right) \tag{11.4.101}$$

11.4.2.3.2 Transient equilibrium

This type of relation between mother and daughter activity occurs when the half-life of the mother nucleus is greater than that of the daughter nucleus (but not much much greater in contrast to the secular equilibrium). In other words, the decay radioactivity of the mother nucleus and the activity of the descendants are equal to a constant factor (in other words, their radioactive decay curves are parallel after a sufficiently long time).

We then in this particular case:

$$\lambda_1 < \lambda_2 \tag{11.4.102}$$

So we have for the activity using the previously prove relation:

$$\lambda_2 N_2(t) = A_2(t) = \frac{\lambda_2 \lambda_1 N_{1_0}}{\lambda_2 - \lambda_1}\left(e^{-\lambda_1 t} - e^{-\lambda_2 t}\right) = \frac{\lambda_2 A_{1_0}}{\lambda_2 - \lambda_1}\left(e^{-\lambda_1 t} - e^{-\lambda_2 t}\right) \tag{11.4.103}$$

After a long enough time, we get:

$$\boxed{A_2(t) \cong \frac{\lambda_2 A_{1_0}}{\lambda_2 - \lambda_1} e^{-\lambda_1} t = \frac{\lambda_2}{\lambda_2 - \lambda_1} A_1(t)} \tag{11.4.104}$$

where we see that the factor:

$$\frac{\lambda_2}{\lambda_2 - \lambda_1} \tag{11.4.105}$$

is greater than unity. So after a sufficiently long time, not only the activity of the daughter isotope is parallel to that of the mother but in addition it is superior to that latter.

11.4.2.3.3 Non-equilibrium

Here the half life time of the daughter element is greater than that of the parent element. In other words we have the hypothesis:

$$\lambda_1 > \lambda_2 \tag{11.4.106}$$

This implies for recall that the probability of decay of the parent element 1 is greater than that of the daughter element 2 which is logical here.

The activity of the daughter isotope in the sample then increases according to the relation proved just above:

$$A_2(t) = \frac{\lambda_2 A_{1_0}}{\lambda_2 - \lambda_1}\left(e^{-\lambda_1 t} - e^{-\lambda_2 t}\right) \tag{11.4.107}$$

Finally, after a sufficiently long time, only the activity of the daughter element will remain, since the activity of the parent element disappears at a higher rate following:

$$\boxed{A_2(t) \cong \frac{\lambda_2 A_{1_0}}{\lambda_2 - \lambda_1}\left(-e^{-\lambda_2 t}\right) = \frac{\lambda_2}{\lambda_1 - \lambda_2} e^{-\lambda_2 t}} \tag{11.4.108}$$

After a time $t_{\max}$, the activity of the daughter element reach a maximum value for:

$$\begin{aligned}\frac{\mathrm{d}A_2(t)}{\mathrm{d}t}=0\cong\frac{\mathrm{d}}{\mathrm{d}t}\left(\frac{\lambda_2 A_{1_0}}{\lambda_2-\lambda_1}\left(e^{-\lambda_1 t}-e^{-\lambda_2 t}\right)\right)&=\frac{\lambda_2 A_{1_0}}{\lambda_2-\lambda_1}\frac{\mathrm{d}}{\mathrm{d}t}\left(e^{-\lambda_1 t}-e^{-\lambda_2 t}\right)\\&=\frac{\lambda_2 A_{1_0}}{\lambda_2-\lambda_1}\left(\lambda_2 e^{-\lambda_2 t}-\lambda_1 e^{-\lambda_1 t}\right)\end{aligned}\tag{11.4.109}$$

Therefore:

$$\frac{\lambda_2 A_{1_0}}{\lambda_2-\lambda_1}\left(\lambda_2 e^{-\lambda_2 t}-\lambda_1 e^{-\lambda_1 t}\right)=0\tag{11.4.110}$$

This simplifies to:

$$\lambda_1 e^{-\lambda_1 t}=\lambda_2 e^{-2\lambda_2 t}\tag{11.4.111}$$

It then comes immediately the result already proved in the example earlier above:

$$t_{\max}=\frac{1}{\lambda_2-\lambda_1}\ln\left(\frac{\lambda_2}{\lambda_1}\right)\tag{11.4.112}$$

Finally, let us consider the extreme case of the situation of non-equilibrium consisting to consider the case where:

$$\lambda_2=0\tag{11.4.113}$$

In other words the daughter element is not radioactive. We then fall back on the classic case:

$$A_2(t)=\frac{\lambda_2 A_{1_0}}{\lambda_2-\lambda_1}\left(e^{-\lambda_1 t}-e^{-\lambda_2 t}\right)=0\tag{11.4.114}$$

11.4.2.4 Radioactive phenomena

When we "weigh" a nucleus, we experimentally observe a very important fact !: its mass is less than the sum of the masses of its constituents. This difference is named the "mass defect" and is relatively well determined with simplistic theoretical models.

The mass defect is given by construction by:

$$\Delta m=Zm_p+(A-Z)m_n-m_{\text{nucleus}}\tag{11.4.115}$$

with m_{nucleus} being the mass of the nucleus in its fundamental state, m_p the proton mass and m_n the neutron mass.

The mass of a set of linked nucleons is less than the sum of the masses of individual nucleons (far enough of each other to not interact). We get from Special Relativity (see section of the same name page 5679):

$$\Delta m=\frac{1}{c^2}E_{\text{bound}}^{\text{nucleons}}\tag{11.4.116}$$

where $E_{\text{bound}}^{\text{nucleons}}$ is the binding energy of the nucleons that compose the nucleus (>0).

Δm is therefore positive for all the elements (emission of energy and therefore of mass to the outer system). If this were not the case, the nucleons have no reason to come together naturally to form stable nuclei (or more stable ...).

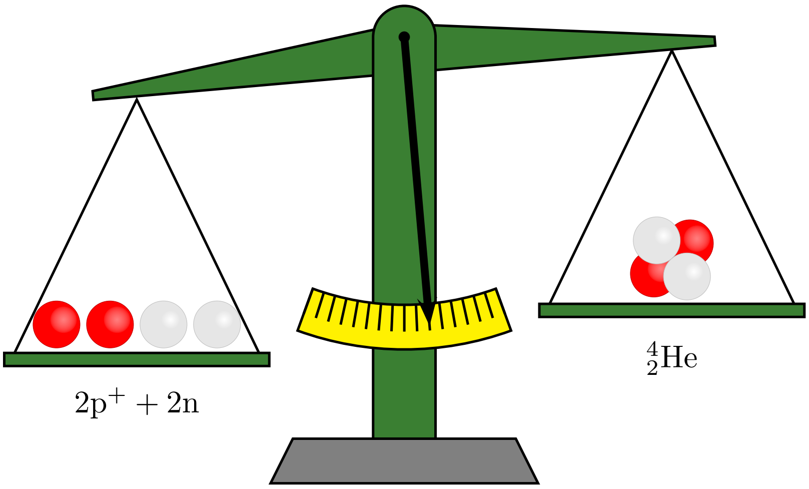


Figure 11.101: Mass defect concept illustrated for Helium

Given $\bar{B}=f(A,Z)$ the average energy by nucleon of a given atom. We have then:

$$\boxed{\bar{B}=\frac{\left[Zm_p+Nm_n-m_{\text{nucleus}}(A,Z)\right]c^2}{A}} \tag{11.4.117}$$

which is by convention a positive value!

Notice that the mass of the nucleus is linked to the mass of the atom by:

$$\boxed{m_{\text{atom}}(Z,A)=m_{\text{nucleus}}(Z,A)+Zm_e} \tag{11.4.118}$$

Similarly, the nucleus mass added to the weight of its isolated electrons is higher than that of the nucleus surrounded by its linked electrons. Let us notice that the electronic binding energy can often neglected relatively to that of the nucleus and it is a rule we will adopt throughout this section.

The energy released during the nuclear fusion, that is to say during the constitution of the atom from its constituents, also named "binding energy" (name that often makes interpretations problems to young students) because it is that energy must be given if we want at the opposite, separate the elements. We must never forget that behind the term "binding energy", so there is the energy variation between individual elements and combined elements of an atomic element.

The general practical expression of the average energy per nucleon of a given atom expressed in atomic mass units is:

$$\bar{B}=\frac{Z\cdot 1.00727647+N\cdot 1.008664904-m_{\text{nucleus}}(A,Z)}{A}\cdot 931.49431\;[\text{MeV}] \tag{11.4.119}$$

A numerical application for Helium (α particle) gives ($Z=N=2,\; A=4$) we get $\bar{B}\cong 7.07$ [MeV/nucleon].

The principles of nuclear energy production from fission or fusion result of the shape of the average energy per nucleon according to A.

We have in reality the following curve linking the average energy per nucleon (that is to say, the average energy variation between the nucleon alone and accompanied...) and the number of nucleons named "Aston curve":

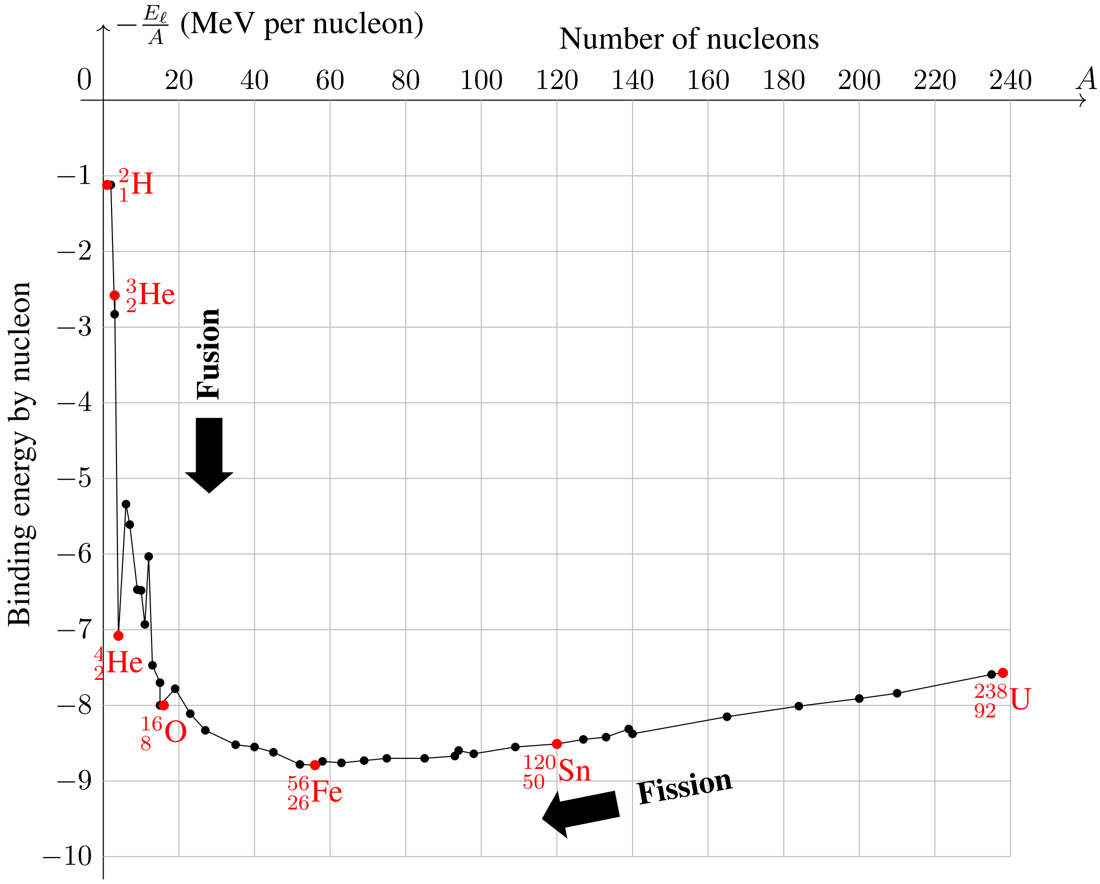

Figure 11.102: Aston curve

where we see that from the Iron the average the energy seems to decrease again (element which is therefore the considered by many undergraduate students as the most "glued" one and therefore the most stable in energy terms because having the highest average bonding energy). This decrease being due to the fact that from about 70 nucleons it seems that appear an electrostatic force inside the nucleus that begins to take over another force that rules in the very small nuclei (this force will be named later the "strong force" or "strong interaction").

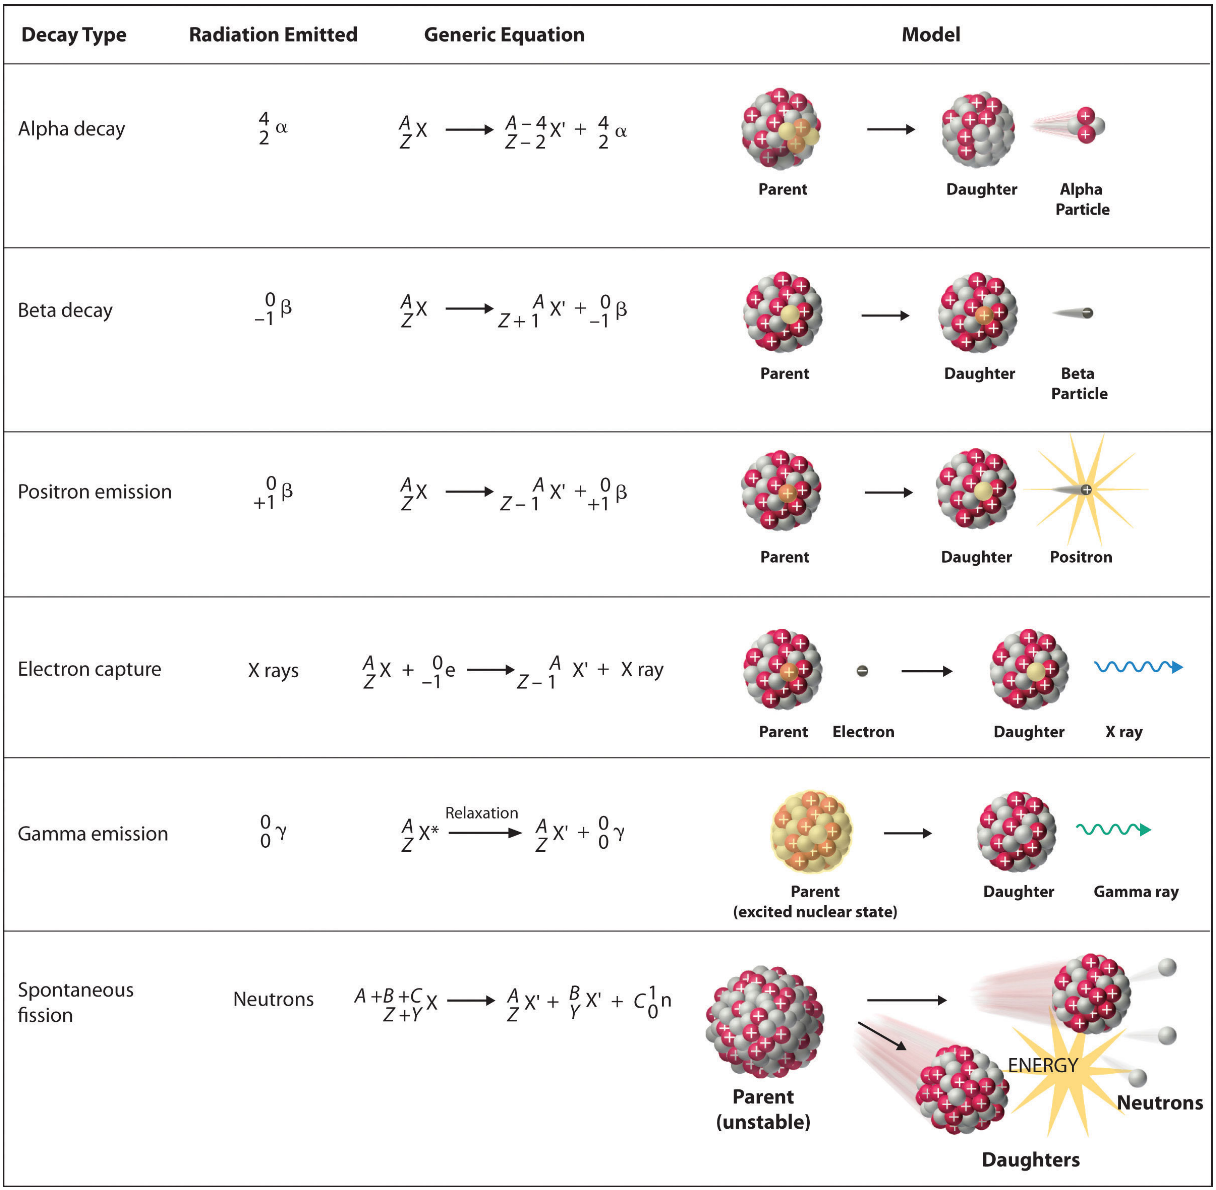
The Aston curve explains why atomic fusion in Stars stops at iron: it's just that the fusion of elements heavier than iron is endothermic rather than exothermic!

Remark

In reality the most stable isotope is Nickel 62 on a binding per energy basis. Iron 58 is second and Iron 56 is third as measured in [180]. Nickel 62 has the highest binding energy per nucleon of any known nuclide (8.7945 [MeV]). It is often stated that ^{56}Fe is the "most stable nucleus", but only because ^{56}Fe has the lowest mass per nucleon (not binding energy per nucleon) of all nuclides. The lower mass per nucleon of ^{56}Fe is possible because ^{56}Fe has $26/56 \approx 46.43\%$ protons, while ^{62}Ni has only $28/62 \approx 45.16\%$ protons; and the larger fraction of lighter protons in ^{56}Fe lowers its mean mass-per-nucleon ratio in a way that has no effect on its binding energy.

By the way, what is really important to notice in the chart above is that there is a inflection point and it is this one that makes it possible to obtain energy both with the nuclear fusion and with nuclear fission! We also see that the variation is much greater on the left than on the right, hence the fact that nuclear fusion releases much more energy.

Of all radioactivity phenomena, we can distinguish 17 of them (alpha decay, beta plus or beta minus decay, positron emission, electron capture, gamma emission, spontaneous fission, double proton emission, neutron emission, double neutron emission, cluster decay, double beta decay, double electron capture, double positron decay, isometric transition, internal conversion), some of them are named "secondary" because they are only the possible side effects of the first 6. Some of these phenomena are caused by man, others are natural and others are purely probabilistic:



Decay Type	Radiation Emitted	Generic Equation	Model
Alpha decay	$^{4}_{2}\alpha$	$^{A}_{Z}X \longrightarrow {}^{A-4}_{Z-2}X' + {}^{4}_{2}\alpha$	Parent → Daughter, Alpha Particle
Beta decay	$^{0}_{-1}\beta$	$^{A}_{Z}X \longrightarrow {}^{A}_{Z+1}X' + {}^{0}_{-1}\beta$	Parent → Daughter, Beta Particle
Positron emission	$^{0}_{+1}\beta$	$^{A}_{Z}X \longrightarrow {}^{A}_{Z-1}X' + {}^{0}_{+1}\beta$	Parent → Daughter, Positron
Electron capture	X rays	$^{A}_{Z}X + {}^{0}_{-1}e \longrightarrow {}^{A}_{Z-1}X' + \text{X ray}$	Parent, Electron → Daughter, X ray
Gamma emission	$^{0}_{0}\gamma$	$^{A}_{Z}X^{*} \xrightarrow{\text{Relaxation}} {}^{A}_{Z}X' + {}^{0}_{0}\gamma$	Parent (excited nuclear state) → Daughter, Gamma ray
Spontaneous fission	Neutrons	$^{A+B+C}_{Z+Y}X \longrightarrow {}^{A}_{Z}X' + {}^{B}_{Y}X' + C\,{}^{1}_{0}n$	Parent (unstable) → Daughters, ENERGY, Neutrons

Figure 11.103: **This table summarizes the type, nuclear equation, representation, and any changes in the mass or atomic numbers for various types of decay (source: `http://chemwiki.ucdavis.edu`)**

A much more exhaustive list of decay modes is given in NUBASE2020 (see [316]):

Mode	Name	Action	Nucleus changes
α	alpha emission	An alpha particle $(A=4, Z=2)$ emitted from nucleus	$(A-4, Z-2)$
p	proton emission	A proton ejected from nucleus	$(A-1, Z-1)$
$2p$	2-proton emission	Two protons ejected from nucleus simultaneously	$(A-2, Z-2)$
n	neutron emission	A neutron ejected from nucleus	$(A-1, Z)$
$2n$	2-neutron emission	Two neutrons ejected from nucleus simultaneously	$(A-2, Z)$

ε	electron capture	A nucleus captures an orbiting electron and emits a neutrino; the daughter nucleus is left in an excited unstable state	$(A,Z-1)$
e^+	positron emission	A nuclear proton converts to a neutron by emitting a positron and an electron neutrino	$(A,Z-1)$
β^+ $\varepsilon+\mathrm{e}^+$	positron emission	In NUBASE2020, β^+refers to the combined rate of electron capture (ε) and positron emission (e^+): $\beta^+=\varepsilon+e^+$	$(A,Z-1)$
β^-	β^-decay	A nucleus emits an electron and an electron antineutrino	$(A,Z+1)$
$\beta^-\beta^-$ $2\beta^-$	double β^-decay	A nucleus emits two electrons and two antineutrinos	$(A,Z+2)$
$\beta^+\beta^+$ $2\beta^+$	double β^+decay	A nucleus emits two positrons and two neutrinos	$(A,Z-2)$
β^-n	β^--delayed neutron emission	A nucleus decays by β^-emission to an excited state, which then emits a neutron	$(A-1,Z+1)$
β^-2n	β^--delayed 2-neutron emission	A nucleus decays by β^-emission to an excited state, which then emits two neutrons	$(A-2,Z+1)$
β^-3n	β^--delayed 3-neutron emission	A nucleus decays by β^-emission to an excited state, which then emits three neutrons	$(A-3,Z+1)$
β^+p	β^+-delayed proton emission	A nucleus decays by β^+emission to an excited state, which then emits a proton	$(A-1,Z-2)$
β^+2p	β^+-delayed 2-proton emission	A nucleus decays by β^+emission to an excited state, which then emits two protons	$(A-2,Z-3)$
β^+3p	β^+-delayed 3-proton emission	A nucleus decays by β^+emission to an excited state, which then emits three protons	$(A-3,Z-4)$
$\beta^-\alpha$	β^--delayed alpha emission	A nucleus decays by β^-emission to an excited state, which then emits an α particle	$(A-4,Z-1)$
$\beta^+\alpha$	β^+-delayed alpha emission	A nucleus decays by β^+emission to an excited state, which then emits an a particle	$(A-4,Z-3)$
β^-d	β^--delayed deuteron emission	A nucleus decays by β^-emission to an excited state, which then emits a deuteron	$(A-2,Z)$

$\beta^{-}t$	β^{-}-delayed triton emission	A nucleus decays by β^{-}emission to an excited state, which then emits a triton	$(A-3, Z)$
CD	cluster decay	A nucleus emits a specific type of smaller nucleus (A_1, Z_1) which is larger than an alpha particle (e.g. $^{14}\mathrm{C}, {}^{24}\mathrm{Ne}$)	$(A-A_1, Z-Z_1)$ & (A_1, Z_1)
IT	internal (isomeric) transition	A nucleus in a metastable state drops to a lower energy state by emitting a photon or ejecting an electron	(A, Z)
SF	spontaneous fission	A nucleus disintegrates into two or more smaller nuclei and other particles, all of which may vary with each decay	variable
β^{+}SF	β^{+}-delayed fission	A nucleus decays by β^{+}emission to an excited state, which then undergoes spontaneous fission	$\beta+$ & variable
β^{-}SF	β^{-}-delayed fission	A nucleus decays by β^{-}emission to an excited state, which then undergoes spontaneous fission	β^{-}& variable

Below is a diagram representing at the top the "valley of stability" of atoms and isotopes and down the same valley but highlighting the type of disintegration:

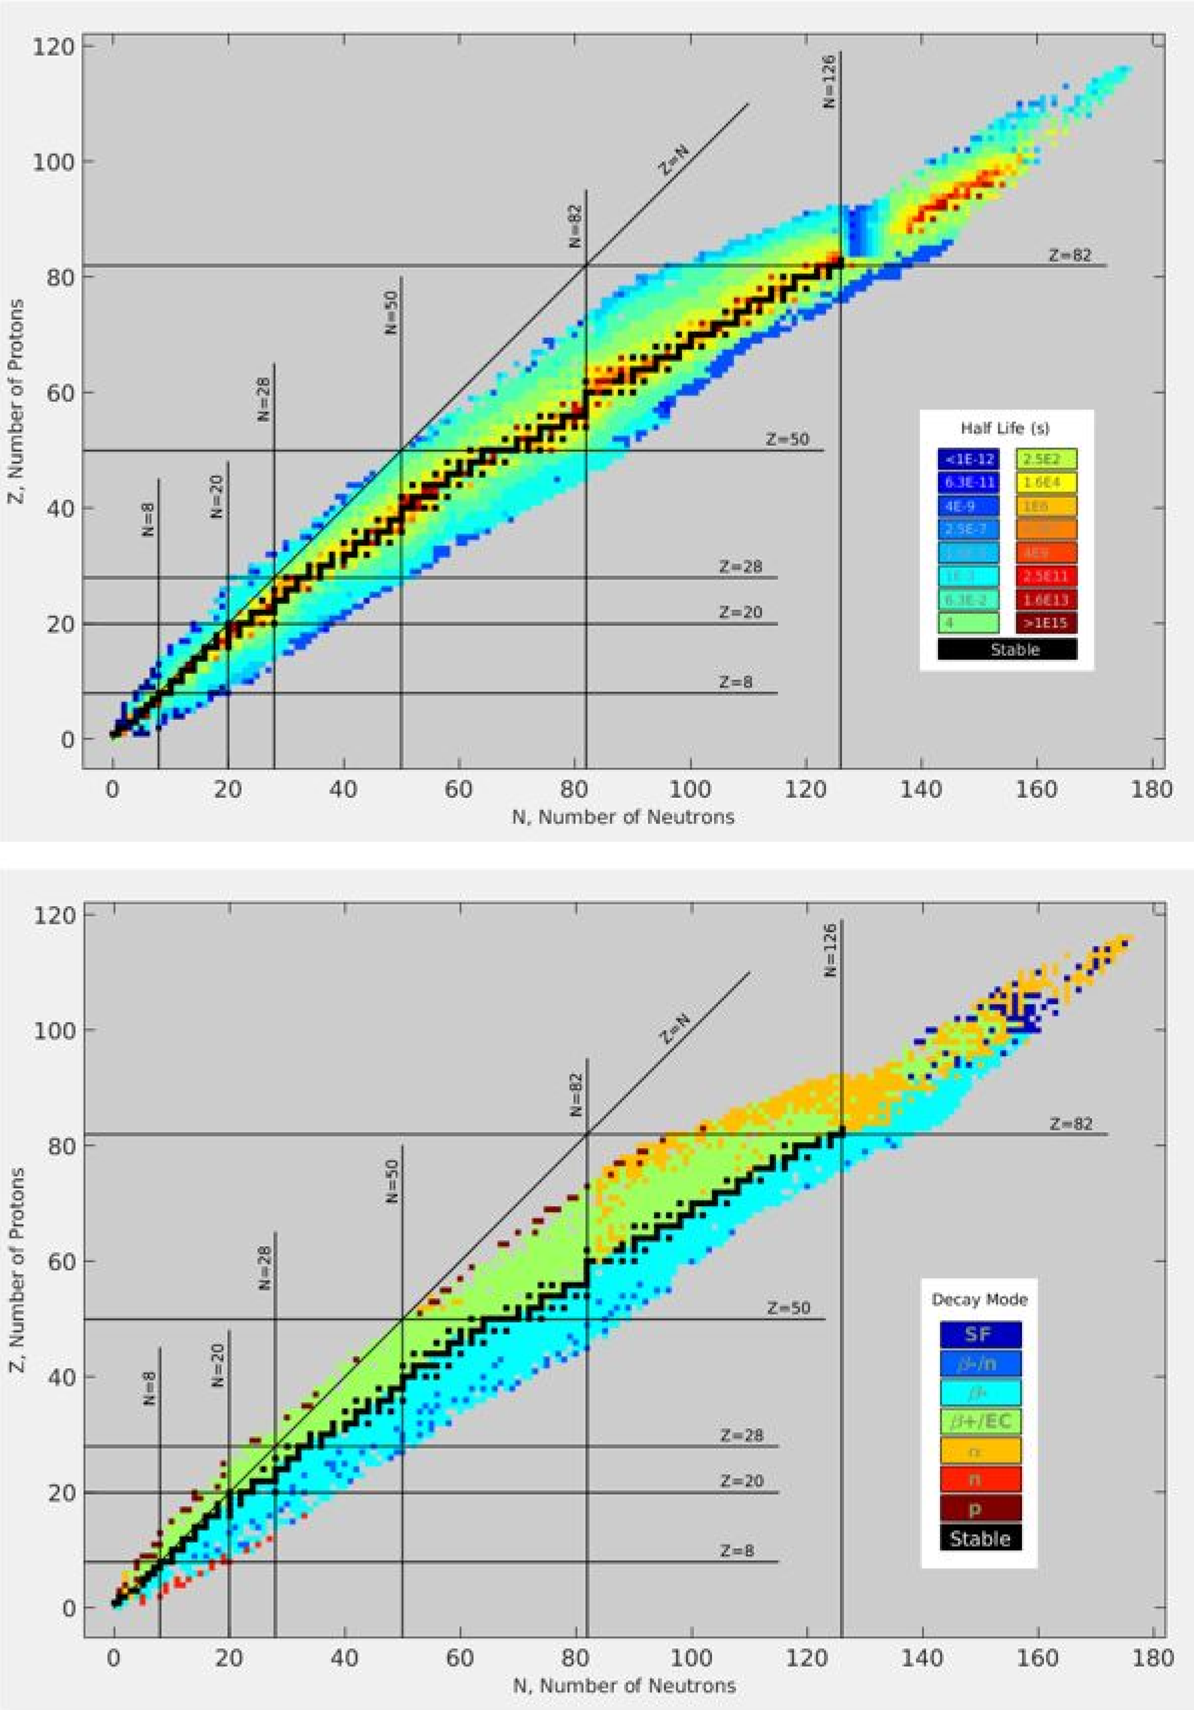


Figure 11.104: Nuclear stability valley (source: Wikipedia)

As the reader can notice it, we have experimental evidence that many elements with equal number of protons and neutrons ($Z=N$) are radioactive.

Let us see then the types of disintegration or modifications of the structure of the atom / nucleus which are possible in this details:

11.4.2.4.1 Nuclear Fusion (1)

If we assemble two light nuclei ${}^{A_x}_{Z_X}\text{X}$ and ${}^{A_Y}_{Z_Y}\text{Y}$ (with $A_x \leq A_y$) to form a "heavy" atom ${}^{A_Z}_{Z_Z}\text{Z}$, then in accordance with the left part of the Aston curve seen above, we increase the mass defect since the average energy per nucleon increases. Indeed:

- The energy of X is equal to:

$$A_X \cdot \bar{B}(A_X, Z_X) = A_X \bar{B}_X \tag{11.4.120}$$

- The energy of Y is equal to:

$$A_Y \cdot \bar{B}(A_Y, Z_Y) = A_Y \bar{B}_Y \tag{11.4.121}$$

- Then energy of Z is equal to:

$$A_Z \cdot \bar{B}(A_Z, Z_Z) = A_Z \bar{B}_Z \tag{11.4.122}$$

As:

$$\bar{B}_X \leq \bar{B}_Y \leq \bar{B}_Z \tag{11.4.123}$$

then:

$$\boxed{\Delta E = A_Z \bar{B}_Z - (A_X \bar{B}_X + A_Y \bar{B}_Y)} \tag{11.4.124}$$

is strictly positive.

Nuclear fusion is almost exclusively caused by man (on Earth at least... because the stars do it alone with the help of gravity). The probability of observing a natural nuclear fusion under normal conditions of temperature and pressure is so low that it is unnecessary to speak of it at least to this day...

The three most common method for achieving fusion are so far:

- Thermonuclear fusion (heated gas under the form of a plasma in analogy with what happens in Stars)
- Inertial confinement fusion (compression of a fuel target with LASER)
- Inertial electrostatic confinement (use of electric field to heat ions to fusion conditions)

For more information about plasma the reader can reefer to the corresponding section in this textbook.

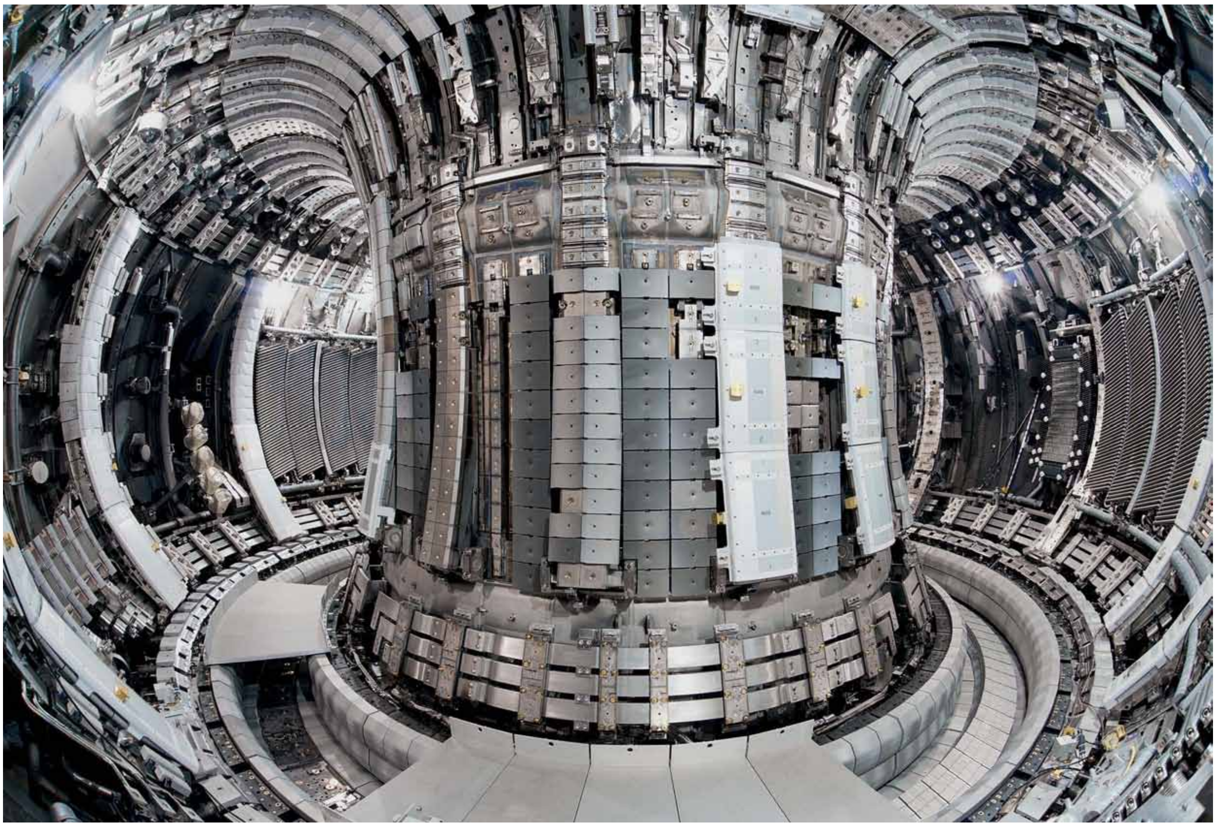

Figure 11.105: Joint European Torus (JET) tokamak fusion detector (source: EUROfusion)

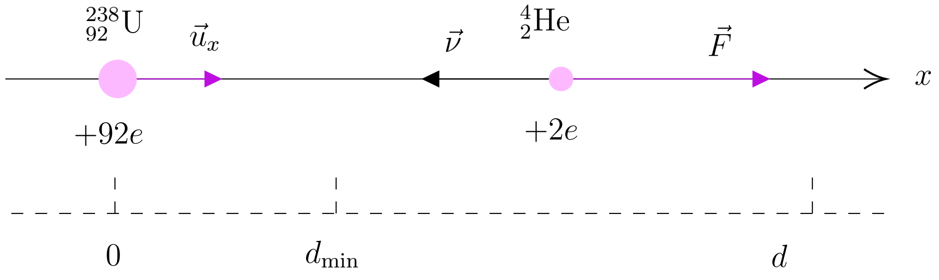
Let us consider now a typical important calculation in the field of nuclear fusion: A helium nucleus ${}^{4}_{2}\mathrm{H}^{2+}_{2}$ is sent with an incident kinetic energy of $E^i_c = 30$ [MeV] towards an uranium nucleus ${}^{238}_{92}\mathrm{U}$ at rest. What is the minimum approach distance between the two cores knowing that the initial distance between the two particles is equal to $d = 10$ [cm].

The two nuclei being positively charged, their electrostatic repulsion along an axis x passing through the two nuclei, is all the stronger as the two nuclei approach each other (see figure below). The minimum approach distance between the two nuclei (d_{min}) is the one for which the speed of the helium nucleus cancels out to change direction. By using the kinetic energy theorem applied between the initial moment when the distance separating the nuclei is d and the moment when this distance is minimal we obtain:



$$\Delta E_c = W_{(F)} \Rightarrow 0 - E_c^i = \int\limits_{d}^{d_{\min}} \vec{F} \circ \mathrm{d}x\vec{u}_x \tag{11.4.125}$$

But the electric force is given by:

$$\vec{F} = \frac{92q_e \cdot 2q_e}{4\pi\varepsilon_0 \cdot x^2}\vec{u}_x \tag{11.4.126}$$

and by the integral:

$$\int\limits_{d}^{d_{\min}} \vec{F} \circ \mathrm{d}x\vec{u}_x = \int\limits_{d}^{d_{\min}} F \cdot \mathrm{d}x = \frac{184q_e^2}{4\pi\varepsilon_0}\left[\frac{-1}{x}\right]_d^{d_{\min}} = \frac{184q_e^2}{4\pi\varepsilon_0}\left(\frac{1}{d} - \frac{1}{d_{\min}}\right) = -E_c^i \tag{11.4.127}$$

The minimum approach distance is therefore:

$$\frac{1}{d_{\min}} = \frac{1}{d} + \frac{4\pi\varepsilon_0 E_c^i}{184q_e^2} \tag{11.4.128}$$

The kinetic energy is given in [Mev] (with as a reminder $1[\text{Mev}] = q_e \cdot 10^6$ [J]). We can therefore write:

$$\frac{4\pi\varepsilon_0 E_c^i}{184q_e^2} = \frac{1}{9.10^9}\frac{30 \cdot 10^6 q_e}{184 \cdot q_e^2} = \frac{10^{17}}{184 \cdot 4.8} = \frac{1}{0.88 \cdot 10^{-14}}\,[\text{m}^{-1}] \tag{11.4.129}$$

By comparing:

$$\frac{1}{d} = \frac{1}{0.1} = 10\,[\text{m}^{-1}] \tag{11.4.130}$$

we see that $1/d$ is negligible before the other term. We then have:

$$\frac{1}{d_{\min}} \cong \frac{1}{0.88 \cdot 10^{-14}} \Rightarrow d_{\min} \cong 0.88 \cdot 10^{-14}\,[\text{m}] = 8.8\,[\text{fermis}] \tag{11.4.131}$$

The most primitive fusion reaction provides the primary source of energy generation on the sun. It is given by:

$${}_1^1\text{H} + {}_1^1\text{H} \rightarrow {}_1\text{H}^2 + e^+ + v_e \quad (Q = 1.44\,[\text{MeV}]) \tag{11.4.132}$$

Here ${}_1^1\text{H}$ is a proton and ${}_1^2\text{H}$ is a deuteron, e^+ is a positron, and v_e is an electron-neutrino. Because of the repulsive force on the protons caused by their positive charge, the reaction rate for this process is very small at low temperatures. Furthermore, the release of a positron and a neutrino shows that this reaction is a weak interaction, causing a reduction in reaction probability over interactions with a reaction using the strong force.

For this reaction to take place, one might think that the particle energies mus be high enough for them to physically touch, treating the particles as billiard ball like objects. A simple calculation shows that this requires very high energies. The potential energy generated by moving the two protons together, each having a radius of about 1.2 [fm] is given by:

$$E_{\textbf{Coul.}} = \frac{q_e^2}{4\pi\varepsilon_0\,(r_p + r_p)} = \frac{1.44\,[\text{MeV} \cdot \text{fm}^{-1}]}{2.4\,[\text{fm}]} = 600\,[\text{keV}] \tag{11.4.133}$$

Since the Sun's core temperature (in plasma physics, always written in energy units, i.e. multiplied by Boltzmann's constant kT and then suppressing the k) is 1.335 [keV] (about 15.5 million Kelvin) we can see that the average energy per particle $(3/2)T$ is much less than this potential energy quoted above.

Let's see another approach of the problem! In order to fuse two nuclei it is first necessary to surmount the potential barrier (or Coulomb barrier) set by the electrostatic repulsion. The height of the Coulomb barrier between two nuclei can be estimated using the equation:

$$E_{\textbf{Coul.}}=\frac{Z_1Z_2q_e^2}{4\pi\varepsilon r} \tag{11.4.134}$$

where Z_1 and Z_2 are the number of protons in each of the two nuclei. Setting $r=10^{-15}\,[\text{m}]$, $Z_1=Z_2=1$, the charge on the electron $q_e\cong 1.60\cdot 10^{-19}\,[\text{C}]$ and the permittivity of free space $\varepsilon_0=8.85\cdot 10^{-12}\,[\text{C}^2\cdot\text{N}^{-1}\cdot\text{m}^{-2}]$, we get a potential energy of $2.3\cdot 10^{-13}\,[\text{J}]$ or $1.4\,[\text{MeV}]$ for the height of the Coulomb barrier, i.e.:

$$E_{\textbf{Coul.}}=\frac{Z_1Z_2q_e^2}{4\pi\varepsilon r}=\frac{1.44Z_1Z_2}{r}\cong 2.3\cdot 10^{-13}\,[\text{J}] \tag{11.4.135}$$

Now, let's compare the average kinetic energy of a Hydrogen nucleus in the center of a Star like the Sun. For $T_c\approx 1.5\cdot 10^7\,[\text{K}]$ we have:

$$E_{\text{th}}=kT_c\cong 1.29\cdot 10^3\,[\text{eV}]=1.29\,[\text{keV}] \tag{11.4.136}$$

The relative velocity v of pairs of particles follow a Maxwell speed distribution (see section Statistical Mechanics page 3554) :

$$\mathrm{d}P(E)=\frac{2}{\sqrt{\pi}}\frac{E^{1/2}}{(kT)^{3/2}}e^{-E/kT}\mathrm{d}E \tag{11.4.137}$$

Therefore (we do a numerical integration as no closed form is known):

$$P=\int\limits_{2.3\cdot 10^{-13}}^{+\infty}\frac{2}{\sqrt{\pi}}\frac{E^{1/2}}{(kT)^{3/2}}e^{-E/kT}\mathrm{d}E\cong 10^{-70} \tag{11.4.138}$$

Therefore the probability of a pair of particles having enough kinetic energy to overcome the Coulomb barrier is $P\cong 10^{-70}$. The total number of nuclei in the Sun (actually a G2V-type star, aka yellow dwarf) is approximately given by its mass divided by the mass of a hydrogen atom, i.e. $1.99\cdot 10^{30}/1.67\cdot 10^{-27}\cong 10^{57}$. Even with $\sim 10^{57}$ nucleons, there is almost no chance of fusion! In order to overcome the Coulomb barrier, therefore, the temperature would have to be of the order of 10^{10} [K]. This is nearly four orders of magnitude higher than the minimum mean temperature of the Sun! Hence we need to consider quantum mechanical tunnelling through Coulomb barrier!

However, quantum mechanics tells us that the protons are not discrete particles but rather must be regarded as having a wave function and have a probability distribution in space that includes places where they would not physically be allowed to exist under the laws of Classical Mechanics. Let us see a first rough approach:

For tunneling, p-p separation should be comparable to de Broglie (dB) wavelength:

$$\lambda_{\text{dB}}=\frac{h}{p}=\frac{h}{\sqrt{2m_pE}} \tag{11.4.139}$$

As a second condition for tunneling, the kinetic energy of the proton must be comparable to the electrostatic potential U at that separation:

$$U_{\text{Coulomb}}=\frac{q_e^2}{4\pi\varepsilon_0}\frac{1}{\lambda_{\text{dB}}}=\frac{e^2}{4\pi\varepsilon_0}\frac{(2m_pE)^{1/2}}{h}\cong E \qquad (11.4.140)$$

Solving for E gives the minimum kinetic energy for tunneling in this rough approach:

$$E\cong\left(\frac{q_e^2}{4\pi\varepsilon_0}\right)^2\frac{2m_p}{h^2}\cong 3\,[\text{keV}] \qquad (11.4.141)$$

Which is comparable to the average kinetic energy in the Sun's core of $2\,[\text{keV}]$.

A much more rigorous calculation of this process was done by Gamow and this adds a "tunnelling factor" to the cross section, given by:

11.4.2.4.2 Nuclear Fission (2)

Similarly (for the theoretical treatment of fission based on quantum physics see the Wave Quantum Physics section at page 4840), if we break with adequate tools (often with neutrons because to approach the nucleus and overcome its electrostatic repulsion it is the appropriate way... and this is the method used by nuclear power plant and nuclear bombs) an heavy atom ${}^{A_X}_{Z_X}\text{X}$ in two light atoms ${}^{A_Y}_{Z_Y}\text{Y}$ and ${}^{A_Z}_{Z_Z}\text{Z}$ (with $A_Y\leq A_Z$) we also increase the mass defect and the energy gained is therefore equal to:

$$\boxed{\Delta E=(A_Y\bar{B}_Y-A_Z\bar{B}_Z)-A_X\bar{B}_X} \qquad (11.4.142)$$

That it is in the case of fission or fusion, the energy released is then divided into the kinetic energy of the fission products, the neutrons emitted and finally the various radiations.

The first reported nuclear fission occurred in 11939 (holocene calendar) when three German scientists, Lise Meitner, Otto Hahn, and Fritz Strassman, bombarded Uranium 235 atoms with slow-moving neutrons that split the Uranium 238 nuclei into smaller fragments that consisted of several neutrons and elements near the middle of the periodic table. Since then, fission has been observed in many other isotopes, including most actinide isotopes that have an odd number of neutrons. A typical nuclear fission reaction (one of the three of ${}^{235}_{92}\text{U}$) is shown below:

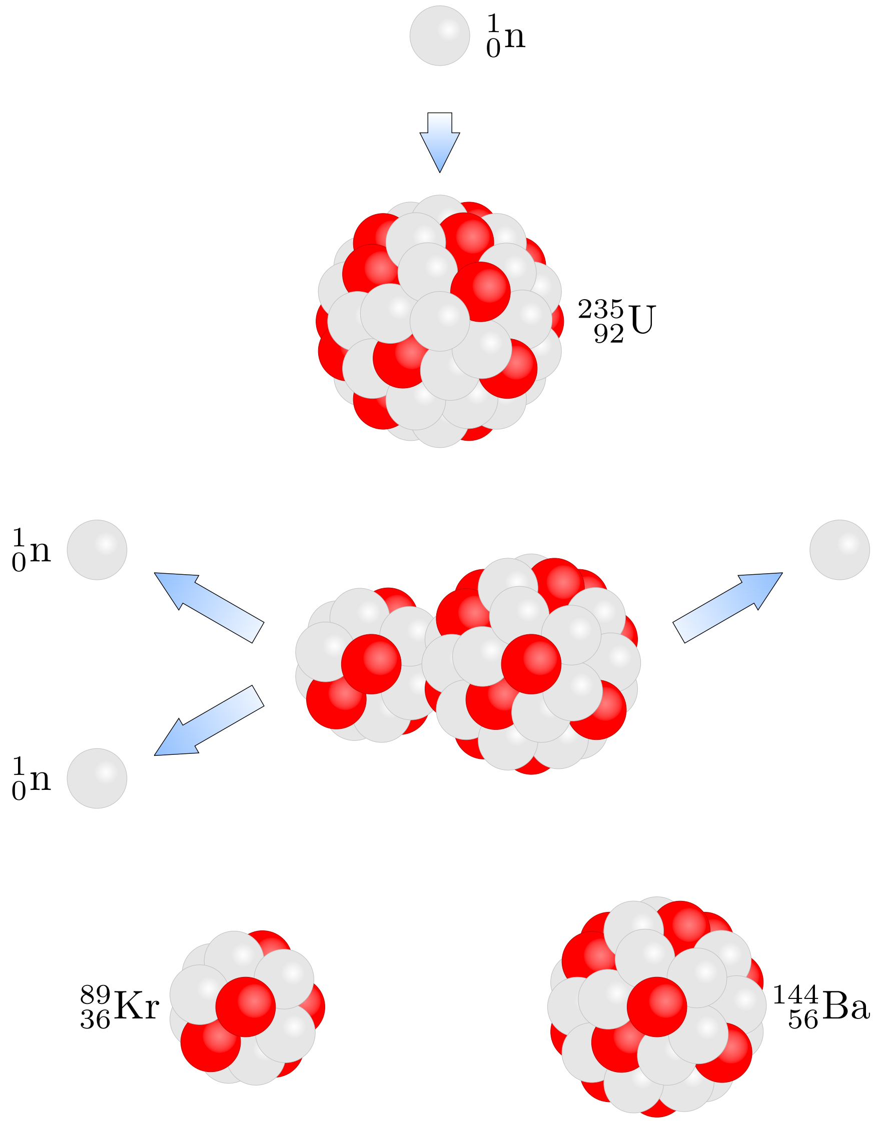


Figure 11.106: **Nuclear fission by a slow neutron of Uranium 235 with its fission products**

Remark

An atom is said to be "fissible" (or sometimes "fissionable") when fast neutrons are needed to produce fission and "fissile" when it is enough to have slow neutrons for fission (which is more rare).

Or another $^{235}_{92}$U fission reaction as seen when a chain reaction occurs:

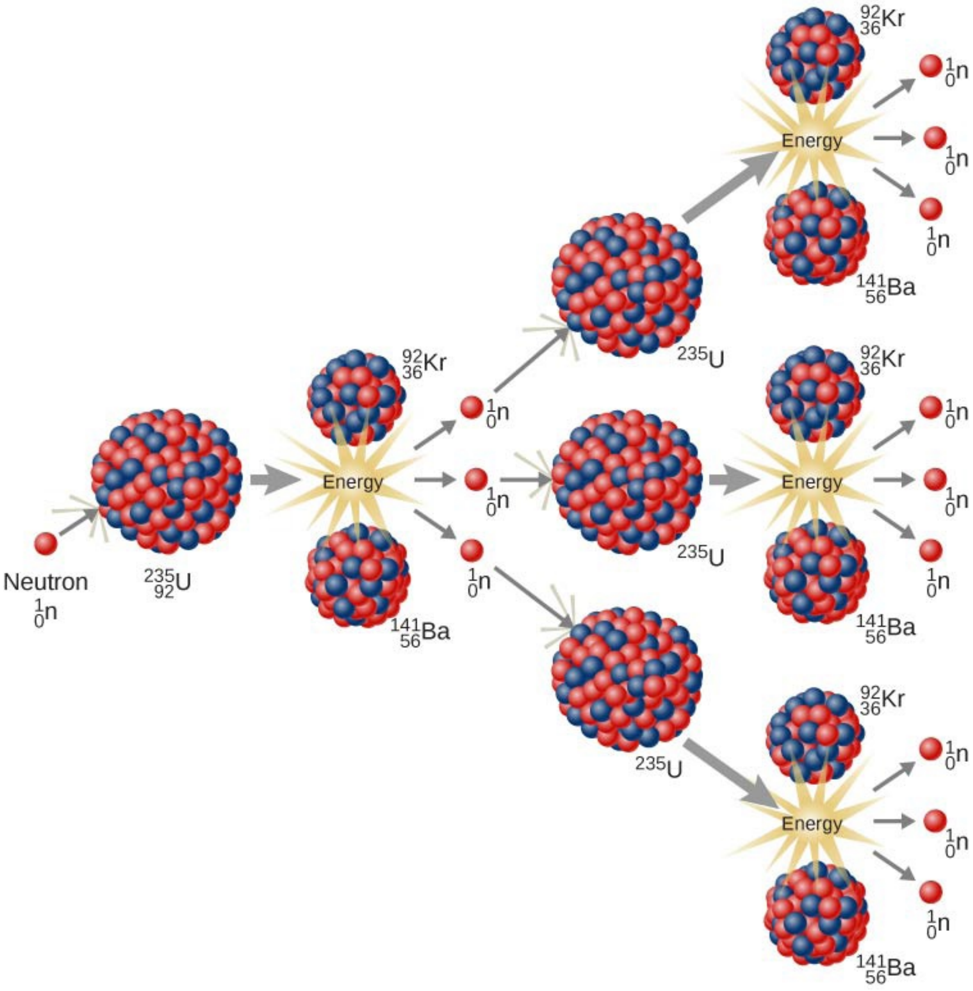

Figure 11.107: **One of Uranium 235 fission chain reaction (source: OpenStax)**

Explicitly:

$$^{235}_{92}\mathrm{U}+{}^1_0n\rightarrow 3^1_0n+{}^{92}_{36}\mathrm{Kr}+{}^{141}_{56}\mathrm{Ba}+170\,[\mathrm{MeV}] \tag{11.4.143}$$

Nuclear energy is by far one of the most concentrated form of energy, since 1 kilogram of natural Uranium supplies a heat quantity of $100,000$ [kWh] in a current power plant, while 1 kilogram of coal supplies by burning only 8 [kWh]. For this reason, only a relatively small amount of nuclear fuel is used for electricity production: a nuclear power plant with an electrical capacity of $1,000$ [MW] consumes 27 tons of enriched Uranium annually, one quarter of its load, whereas a thermal power plant of the same power consumes $1,500,000$ tons of oil by year... For comparison in the Sun, 1 kilogram of hydrogen produced, by nuclear reactions transforming it into helium, 180 million kWh!!!! But beware, industrially we know how to extract only a small part of the nuclear energy stored in the material. Of the 27 tons of enriched Uranium consumed in one year by a power plant, only a small amount of nucleus was really consumed (hence the economic need to reprocess the Uranium after use).

We quickly realize that the calorific value of fission is gigantic compared to that of fossil energies. An estimate gives a ratio of energy released per atom of $50,000$ million !!! On the other hand, the risk ratio in terms of exploitation and management of waste and impact on the environment is of the same order but in the opposite direction. That mankind finds either another way of producing electricity, or changes its habits of consumption.

For information in Switzerland, there are only 5 at this nuclear power plants (at the beginning of the 121st century according to the holocene calendar) for a population of almost 7 million individuals in year 12000 (holocene calendar):

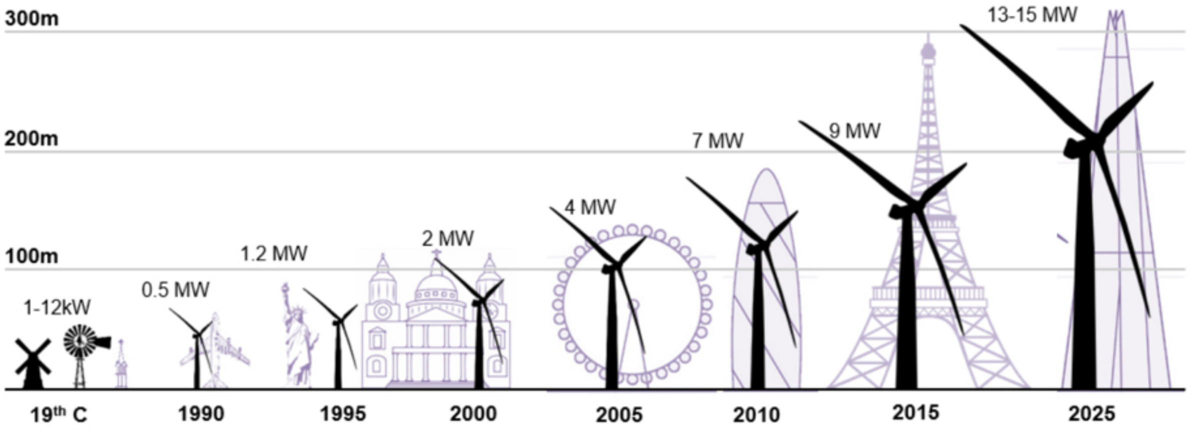
Gösgen	1978	970 MW, Pressurized water
Leibstadt	1984	1165 MW Boiling water

Figure 11.108: **Nuclear power plants in Switzerland at the end of the 120th century (source: Swiss confederation)**

It may be interesting for the reader to compare the power capacity of the swiss nuclear plants to the 121st century (holocene calendar) state of the art windmills:



Sources: Various; Bloomberg New Energy Finance

This little introduction being made, let us return to the purely mathematical part!

In the case of spontaneous (or natural) fission we have the emission of two fission products and of w neutrons. What we denote by:

$$ {}_{Z}^{A}\mathrm{X} \rightarrow {}_{\nu}^{M}\mathrm{Y} + {}_{Z-\nu}^{A-M-w}\mathrm{Z} + w\,{}_{0}^{1}n \qquad (11.4.144)$$

✍**Example:**

The isotope of Carbon 15 by spontaneous fission gives an isotope of Nitrogen with the emission of an electron and an antineutrino:

$$ {}^{15}_{8}\mathrm{C} \rightarrow {}^{15}_{7}\mathrm{N} + \beta^{-} + \bar{\nu} \tag{11.4.145} $$

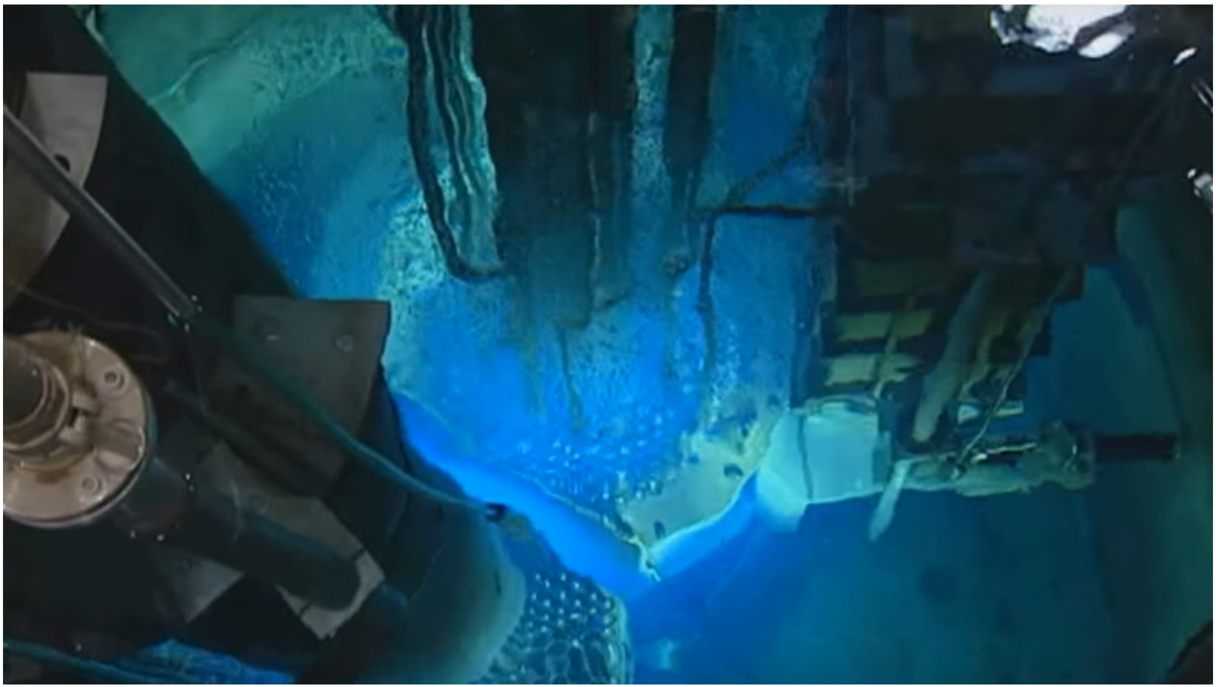


Figure 11.109: **Sandia National Laboratories' Annular Core Research Reactor (we can see the bubbles of the evaporated water on the picture)**

At the day we write these lines there are more than 130 fission reactor concepts (the most promising one and most safety one seems to be the MSR - Molten Salt Reactor - however governments like to stay with water pressured reactors for historical, economical and educational reasons that are debatable... Inertia is sadly hard to change). The reader can see below only a few of them in two different figures (we were not able to find who are the artists):

Figure 11.110: Types of nuclear reactors (author: ?)

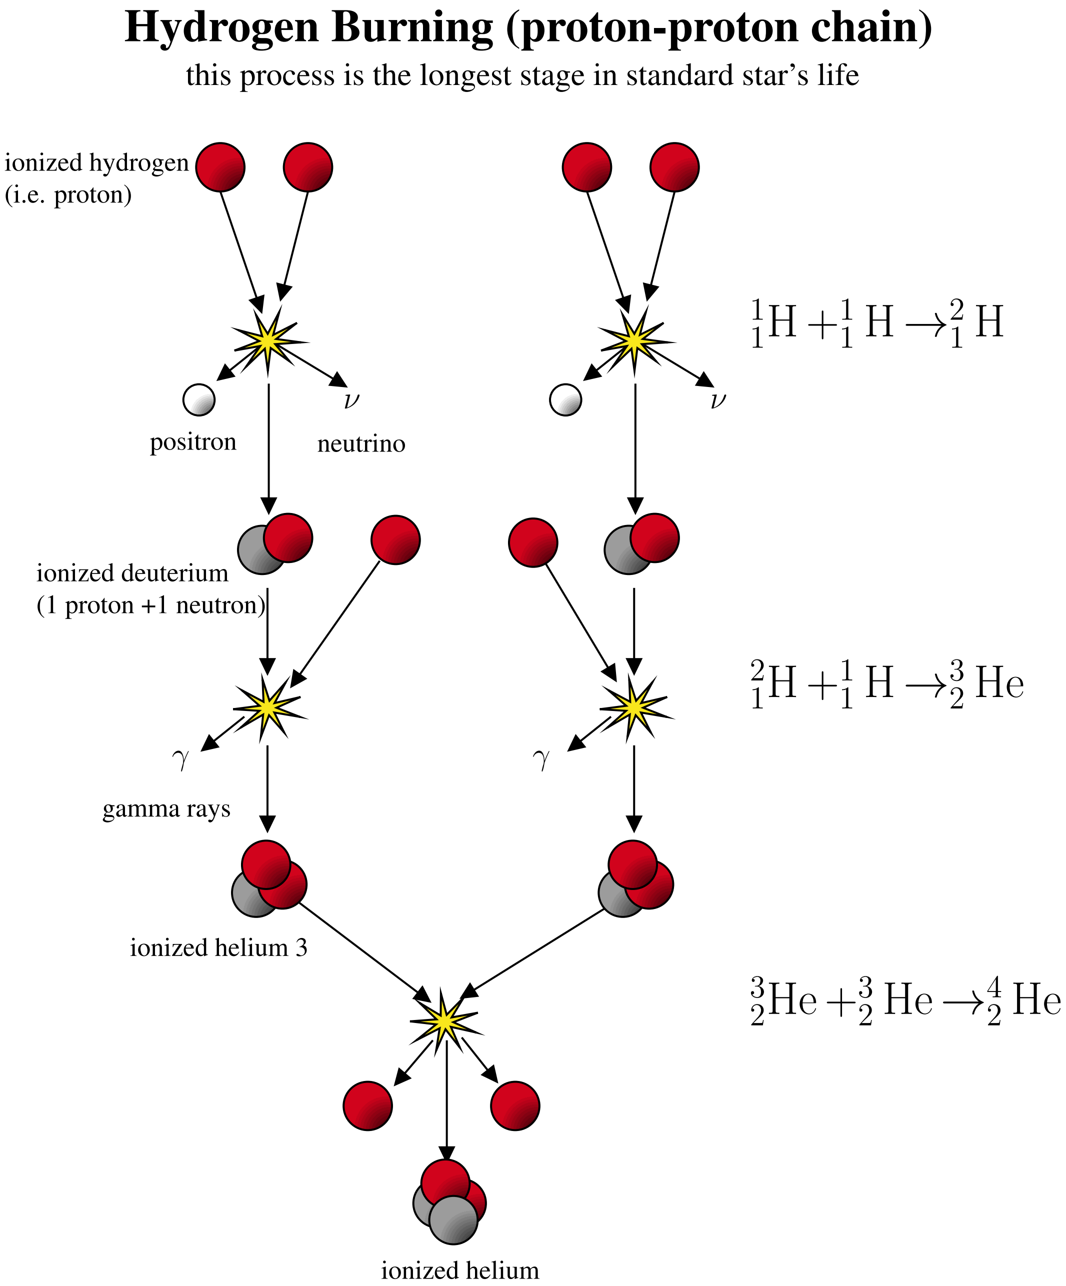
Now it's quite important to notice something!:

The fission of one atom of ${}^{239}\mathrm{Pu}$ generates $207.1\,[\mathrm{MeV}] = 3.318 \cdot 10^{-11}\,[\mathrm{J}]$, according to the following reaction:

$${}_{94}\mathrm{Pu}^{239} + {}_{0}\mathrm{n}^{1} \longrightarrow {}_{94}\mathrm{Pu}^{240} \longrightarrow {}_{40}\mathrm{Zr}^{103} + {}_{54}\mathrm{Xe}^{134} + 3{}_{0}\mathrm{n}^{1} + 207.1\,\mathrm{MeV} \tag{11.4.146}$$

i.e. $19.98\,[\text{TJ}\cdot\text{mol}^{-1}] = 83.61\,[\text{TJ}\cdot\text{kg}^{-1}]$ or about $23\,[\text{GW}\cdot\text{h}\cdot\text{kg}^{-1}]$ of gamma rays.

Now let us consider the following hydrogen fusion chain:



Hydrogen Burning (proton-proton chain)
this process is the longest stage in standard star's life
ionized hydrogen
(i.e. proton)
$^1_1\text{H} + ^1_1\text{H} \rightarrow ^2_1\text{H}$
ν
ν
positron
neutrino
ionized deuterium
(1 proton +1 neutron)
$^2_1\text{H} + ^1_1\text{H} \rightarrow ^3_2\text{He}$
γ
γ
gamma rays
ionized helium 3
$^3_2\text{He} + ^3_2\text{He} \rightarrow ^4_2\text{He}$
ionized helium

Figure 11.111: **Hydrogen fusion (proton-proton chain)**

In the above chain we see that four hydrogen nuclei are involved having a total mass of $6.693\cdot10^{-27}\,[\text{kg}]$. They fuse into a helium nucleus of mass $6.645\cdot10^{-27}\,[\text{kg}]$. Therefore the mass lost is $0.048\cdot10^{-27}\,[\text{kg}]$. Thus, only the fraction $0.048/6.693 = 0.00717$ of the original hydrogen mass was converted to radiation and kinetic energy. In other words, when we start with $1\,[\text{kg}]$ of hydrogen, a mass of $0.00717\,[\text{kg}]$ will be converted to energy radiation and kinetic energy during the fusion. This gives an energy output per kilogram:

$$E = mc^2 = 0.00717\cdot c^2 \cong 6.45\cdot10^{14}\,[\text{J}] \qquad (11.4.147)$$

Hence $6.45\cdot 10^2\,[\text{TJ}\cdot\text{kg}^{-1}]$. So for the same mass, Hydrogen fusion in approximation release 10 times more energy than plutonium fission! We can understand why the army is interested in nuclear H bomb (even if the fusion of hydrogen had to be initiated with a plutonium/uranium like implosion) and why the industry is interest to develop fusion nuclear power plants rather than fission one (even if the technical obstacles are huge to master fusion and still not usable in an industrial way in the early 121st century).

11.4.2.4.3 Alpha Disintegration (3)

Definition (#11.4.514): When a heavy nucleus contains too many protons and neutrons (like Uranium 238 for example), it will empty its nucleon overflow by emitting an alpha particle (Helium nucleus composed of 2 protons and 2 neutrons) and the final system which will be a new nucleus will have a smaller and possibly stable mass. This mode of disintegration is named "alpha radioactivity".

The probability of disintegration is governed by the mechanism of penetration barrier ("Tunnel effect") as we will prove it a little further after a small introduction.

The radioactive decay according to the alpha radioactivity can be schematized as (with some small variations depending on the case):

$$ {}^{A}_{Z}\mathrm{X}_{N} \rightarrow {}^{A-4}_{Z-2}\mathrm{X}_{N-2} + {}^{4}_{2}\alpha \tag{11.4.148} $$

where:

$$ {}^{4}_{2}\alpha = {}^{4}_{2}\mathrm{He}_{2}^{++} \tag{11.4.149} $$

✍**Example:**

Radon is found in significant concentrations in underground mines and sometimes in some caves (in some mining or granitic areas):

$$ {}^{222}_{86}\mathrm{Ra} \rightarrow {}^{218}_{84}\mathrm{Po} + \alpha + \gamma \tag{11.4.150} $$

where Polonium is one of the main factors of induction of so-named "radon-induced lung cancers".

The energy released during the transmutation is calculated thanks to the mass default:

$$ \mathrm{Q}_{\alpha} = (M_X - M_y - M_{\mathrm{He}})\cdot c^2 \tag{11.4.151} $$

with M_X being the mass of the initial nucleus, M_Y the mass of the final nucleus and M_{He} the mass of the Helium nucleus.

By neglecting the binding energy of electrons, we have:

$$ M_X = m_X + Zm_e \quad \text{and} \quad M_Y = m_Y + (Z-2)m_e \quad \text{and} \quad m_{\mathrm{He}} = m_{\mathrm{He}} + 2m_e \tag{11.4.152} $$

Finally:

$$ \boxed{\mathrm{Q}_{\alpha} \cong (m_X - m_y - m_{\mathrm{He}})\cdot c^2} \tag{11.4.153} $$

This expression shows that the energy of α particle is well defined for given initial and final nuclei. In fact, we actually observe a discrete energy spectrum. We conclude that these emissions lead the nucleus to intermediate energy levels corresponding to excited states of the final nucleus. We can explain these observations by a layered nuclear structure!!! The de-excitation of the final is done by emission of γ photons.

The conservation of energy requires that the energy of the α disintegration is distributed between the kinetic energy of the two residual products:

$$\mathrm{Q}_\alpha = E_c^{\text{nucleus}} + E_c^\alpha = \frac{1}{2}m_{\text{nucleus}}v_{\text{nucleus}}^2 + \frac{1}{2}m_\alpha v_\alpha^2 \tag{11.4.154}$$

The conservation of the linear momentum gives us:

$$p_{\text{nucleus}} = m_{\text{nucleus}} \cdot v_{\text{nucleus}} = p_\alpha = m_\alpha v_\alpha \tag{11.4.155}$$

and therefore:

$$v_{\text{nucleus}} = \frac{m_\alpha}{m_{\text{nucleus}}} v_\alpha \tag{11.4.156}$$

which we replace in the energy conservation equation:

$$\begin{aligned}\mathrm{Q}_\alpha &= \frac{1}{2}m_{\text{nucleus}}\left(\frac{m_\alpha}{m_{\text{nucleus}}}v_\alpha\right)^2 + \frac{1}{2}m_\alpha v_\alpha^2 = \frac{m_\alpha}{m_{\text{nucleus}}}\left(\frac{1}{2}m_\alpha v_\alpha^2\right)^2 + \frac{1}{2}m_\alpha \nu_\alpha^2\\ &= \frac{1}{2}m_\alpha v_\alpha^2\left(1+\frac{m_\alpha}{m_{\text{nucleus}}}\right) = E_c^\alpha\left(1+\frac{m_\alpha}{m_{\text{nucleus}}}\right)\end{aligned} \tag{11.4.157}$$

and we derive that the energy of the α particle is equal to:

$$E_c^\alpha = \frac{\mathrm{Q}_\alpha}{\left(1+\dfrac{m_\alpha}{m_{\text{nucleus}}}\right)} = \frac{\mathrm{Q}_\alpha}{\left(\dfrac{m_{\text{nucleus}}+m_\alpha}{m_{\text{nucleus}}}\right)} \cong \frac{\mathrm{A}}{\mathrm{A}+4}\mathrm{Q}_\alpha \tag{11.4.158}$$

since the masses of the nucleus and the α particle are approximately proportional to their mass number, thus A and 4 respectively.

Let us see now the details of the mechanism of α disintegration with an academic approach, simplified to the extreme and therefore approximative (but sufficient nevertheless). For this approach, we will use the developments on the tunnel effect that we have carried out in the section of Wave Quantum Physics.

For nuclei having a nucleon number becoming too large, the Coulomb repulsion between protons takes significant values in comparison to the strong interaction which ensures the cohesion of the nucleus. We then observe a phenomenon of saturation, which gives rise to the α disintegration which is a special case of a spontaneous fission.

George Gamow proposed a theoretical explanation for this phenomenon in 11928 (holocene calendar). He assumes that the particle α pre-exists in the nucleus and bumps on the potential walls. It then has a non-zero probability of crossing the potential barrier of the nucleus by tunnelling.

If by thought we disconnect Coulomb interactions, such an α particle is linked to the rest of the nucleus by a nuclear potential of short range equation and depth corresponding to a potential energy that we will determine.

Schematically in the case of Uranium 238 the situation is considered as follows:

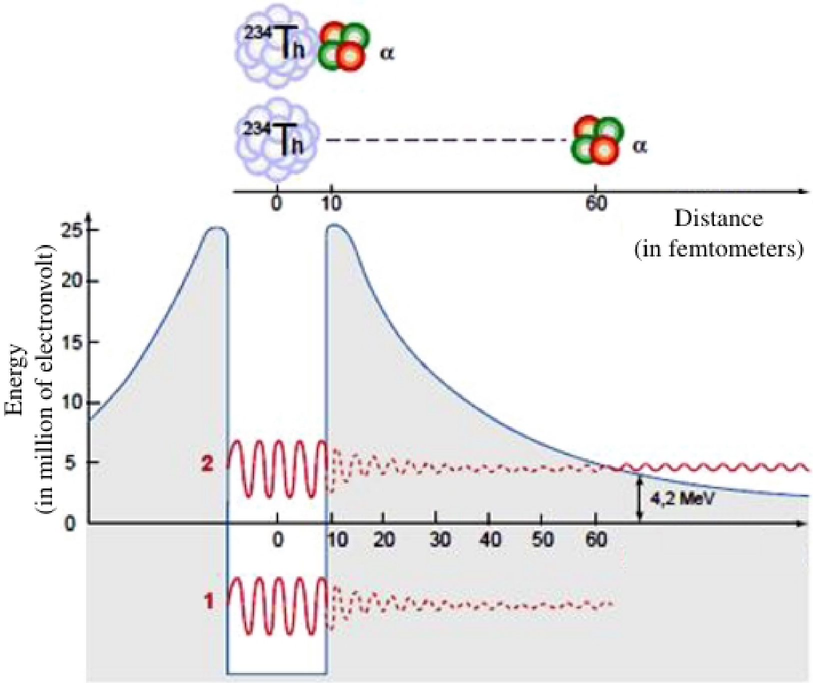


Figure 11.112: **Gamow's idea of Tunnelling effect (source: Pour la Science)**

In Classical Physics we would represent the α emission as the leak of the nucleus from the nucleus. This representation is not valid because it implies that the α particle is undergoing the electrostatic repulsion of the residual core of Thorium 234 would only be removed with an energy of about 25 [MeV]. However, the low experimentally observed value (of only 4.2 [MeV]) is found only with the tool of Quantum Physics.

Let's move on to the mathematical part:

Let us connect the Coulomb repulsion between the α particle of electric charge $+2e$ (two protons and two neutrons) and the rest of the nucleus, then of charge $+(Z-2)e$ outside the nuclear potential well.

We then get the expression of the potential energy (see section Electrostatics page 4005):

$$E_p=\frac{1}{4\pi\varepsilon_0}\frac{(\mathrm{Z}-2)q_e\cdot 2q_e}{r}=\frac{1}{4\pi\varepsilon_0}\frac{2(\mathrm{Z}-2)q_e^2}{r} \tag{11.4.159}$$

Where r is the distance between the center of the nucleus and the α particle. The potential energy therefore decreases with distance since the force is repulsive.

Now, let's have a qualitative approach to the phenomenon. We put that the probability T of tunnelling as being proportional, according to our results in the section of Wave Quantum Physics (see page 4840), to:

$$T \propto e^{-2kL} = \exp\left(-2L\frac{\sqrt{2m(E_p - E_{\text{tot}})}}{\hbar}\right) \tag{11.4.160}$$

knowing that it is, following the approximations we made during the proof, of a lower limit.

If we model the potential barrier of the core by a non-rectangular profile as presented below:

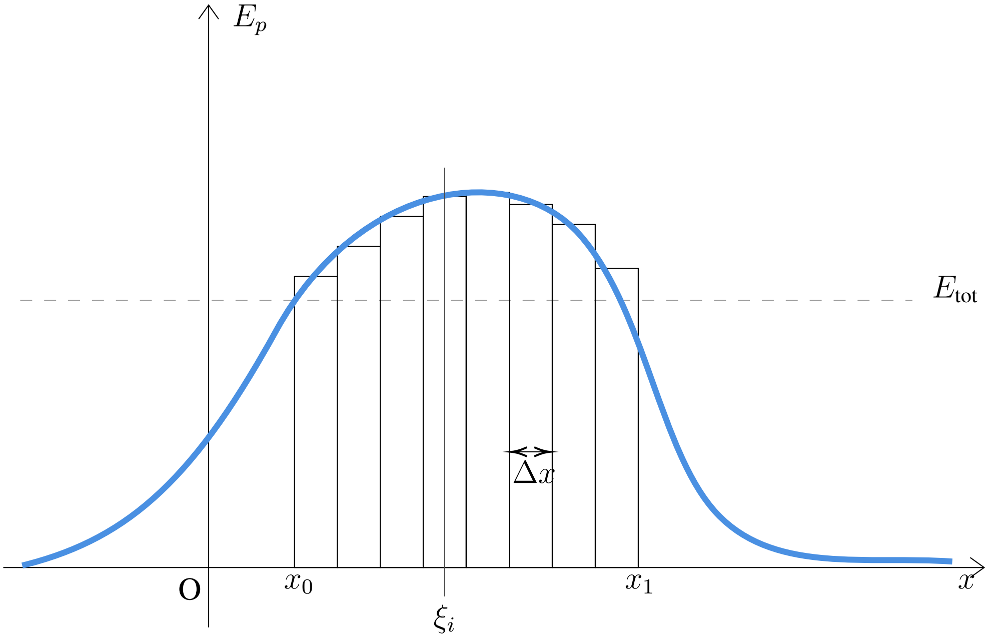

Figure 11.113: **Non-rectangular barrier profile of the nucleus**

where we replace the real profile of the curve by a series of barriers of thickness Δx and where the potential equals E_p at the point ξ_i

The probability of passing a barrier will therefore be proportional to:

$$T_i \propto \exp\left(-\frac{2}{\hbar}\Delta x\sqrt{2m\Big(E_p(\xi_i) - E_{\text{tot}}\Big)}\right) \tag{11.4.161}$$

and we know (see section Probabilities page 480) that the probability of passing one of the barriers is an independent event (mutually exclusive). We can therefore multiply the probabilities such that:

$$T \propto \exp\left(\sum_i -\frac{2}{\hbar}\Delta x\sqrt{2m\Big(E_p(\xi_i) - E_{\text{tot}}\Big)}\right) \tag{11.4.162}$$

And passing to the limit it comes:

$$T \propto \exp\left(-\frac{2}{\hbar}\int_{x_0}^{x_1}\sqrt{2m\Big(E_p(x) - E_{\text{tot}}\Big)}\,\mathrm{d}x\right) \tag{11.4.163}$$

and if x is assimilated to a radius of a spherical symmetry configuration:

$$T \propto \exp\left(-\frac{2}{\hbar}\int\sqrt{2m\left(E_p(r)-E_{\text{tot}}\right)}\mathrm{d}r\right) \tag{11.4.164}$$

Often denoted:

$$T \propto \exp(-2G) \tag{11.4.165}$$

where G is known as the "Gamow factor".

In the case of an α nucleus, the potential barrier ranges from r_1 where it begins to r_2 value where the potential barrier is considered as negligible.

But, the potential energy of the α at any remote point r from the outside of the border of the nucleus of the radioactive atom will be equal, as we have seen a earlier before, to:

$$E_p(r)=\frac{1}{4\pi\varepsilon_0}\frac{2(\mathrm{Z}-2)q_e^2}{r} \tag{11.4.166}$$

We thus have for $r_1 \leq r \leq r_2$:

$$E_p(r)-E_{\text{tot}}=\frac{1}{4\pi\varepsilon_0}\frac{2(\mathrm{Z}-2)q_e^2}{r}-E_{\text{tot}} \tag{11.4.167}$$

To determine E_{tot} of the emitted α nucleus, it is necessary to know that its total energy is supposed preserved in this simplified model. It is therefore the same as before it passes through the nuclear potential barrier when $r_1 \leq r$, during, and after r_2.

Moreover, in this model, kinetic energy is also assumed constant when $r \leq r_2$. In other words, since the α nucleus pre-exists in the nucleus of the radioactive atom, it already has the final velocity that it will have at the point of crossing the barrier of the nuclear potential ...

So under all these very simplifying assumptions... if we know how to determine the total energy of the α nucleus in r_2 (for example), at the output of the barrier, we have its total energy during the whole crossing phenomenon of the barrier.

Conversely, its total energy required to exit in r_2 of the potential barrier by tunnel effect starting from the nucleus of the radioactive atom (and then going away at infinity and gaining kinetic energy and losing all its potential Coulomb energy) is the same assuming that the total energy obtained by calculating the work of the force which from an infinite distance of the nucleus of the radioactive atom would make the α nucleus return inside the nucleus of the radioactive atom at the aforementioned velocity to the minimum exit point r_2 (minimum exit radius taken as constant because very distant in orders of magnitude with respect to the nucleus of the radioactive atom).

This then corresponds to the potential energy difference between a point at infinity and an r_2. And since the potential energy is zero at infinity for a repulsive system, there remains only the term:

$$E_{\text{tot}}=\frac{1}{4\pi\varepsilon_0}\frac{2(\mathrm{Z}-2)q_e^2}{r_2} \tag{11.4.168}$$

and finally:

$$E_p(r)-E_{\text{tot}}=\frac{1}{4\pi\varepsilon_0}\frac{2(\mathrm{Z}-2)q_e^2}{r}-\frac{1}{4\pi\varepsilon_0}\frac{2(\mathrm{Z}-2)q_e^2}{r_2}=\frac{2(\mathrm{Z}-2)q_e^2}{4\pi\varepsilon_0}\left(\frac{1}{r_2}-\frac{1}{r_2}\right) \tag{11.4.169}$$

still valid only for $r_1 \leq r \leq r_2$ (it is as if during the crossing of the barrier, the αnucleus restored kinetic energy to the vacuum as it approach of the point r_2, that said, in Quantum Physics one we cannot use the Classical Mechanics interpretation...).

Now, very often in laboratories, r_2 is expressed as a constant sufficiently far from the nucleus of the radioactive atom. It is then relatively natural (even if it is do-it-yourself physicist way of doing maths...) to take r as an integration variable such as:

$$T\propto\exp\left(-\frac{2}{\hbar}\int\limits_{r_1}^{r_2}\sqrt{\frac{2m2(\mathrm{Z}-2)q_e^2}{4\pi\varepsilon_0}\left(\frac{1}{r}-\frac{1}{r_2}\right)}\mathrm{d}r\right)=\exp\left(-2\frac{1}{\hbar}\sqrt{\frac{m4(\mathrm{Z}-2)q_e^2}{4\pi\varepsilon_0}}\int\limits_{r_1}^{r_2}\sqrt{\left(\frac{1}{r}-\frac{1}{r_2}\right)}\mathrm{d}r\right) \tag{11.4.170}$$

and it is traditional to put:

$$\gamma=\frac{1}{\hbar}\sqrt{\frac{m4(\mathrm{Z}-2)q_e^2r_2}{4\pi\varepsilon_0}} \tag{11.4.171}$$

which brings us to:

$$T\propto\exp\left(-\frac{2\gamma}{\sqrt{r_2}}\int\limits_{r_1}^{r_2}\sqrt{\left(\frac{1}{r}-\frac{1}{r_2}\right)}\mathrm{d}r\right) \tag{11.4.172}$$

Let us now do the following change of variables (the derivative of the $\cos^2(u)$ is detailed in the section of Differential and Integral Calculus at page 1475):

$$\cos^2(u)=\frac{r}{r_2}\Rightarrow\frac{\mathrm{d}r}{\mathrm{d}u}=r_2\frac{\mathrm{d}\cos^2(u)}{\mathrm{d}u}=-r_2 2\cos(u)\sin(u) \tag{11.4.173}$$

hence:

$$\mathrm{d}r=-r_2 2\cos(u)\sin(u)\mathrm{d}u \tag{11.4.174}$$

and by putting:

$$\cos^2(u_0)=\frac{r_1}{r_2} \tag{11.4.175}$$

The integral:

$$\int\limits_{r_1}^{r_2}\sqrt{\left(\frac{1}{r}-\frac{1}{r_2}\right)}\mathrm{d}r \tag{11.4.176}$$

becomes:

$$\begin{aligned}\int\limits_{r_1}^{r_2}\sqrt{\left(\frac{1}{r}-\frac{1}{r_2}\right)}\mathrm{d}r&=\int\limits_{r_1}^{r_2}\sqrt{\frac{1}{r}\left(1-\frac{r}{r_2}\right)}\mathrm{d}r=\int\limits_{r_1}^{r_2}\sqrt{\frac{1}{r}\left(1-\cos^2(u)\right)}\mathrm{d}r=\int\limits_{r_1}^{r_2}\sqrt{\frac{1}{r}\sin^2(u)}\mathrm{d}r\\&=\int\limits_{r_1}^{r_2}\frac{1}{\sqrt{r}}\sin(u)\mathrm{d}r=\int\limits_{r_1}^{r_2}\frac{1}{\sqrt{r_2\cos^2(u)}}\sin(u)\mathrm{d}r=\frac{1}{\sqrt{r_2}}\int\limits_{r_1}^{r_2}\frac{\sin(u)}{\cos(u)}\mathrm{d}r\\&=\frac{1}{\sqrt{r_2}}\int\limits_{r_1}^{r_2}\frac{\sin(u)}{\cos(u)}(-r_2 2\cos(u)\sin(u)\mathrm{d}u)\\&=-\frac{2r_2}{\sqrt{r_2}}\int\limits_{r_1}^{r_2}\sin^2(u)\mathrm{d}u=-2\sqrt{r_2}\int\limits_{r_1}^{r_2}\sin^2(u)\mathrm{d}u\end{aligned}\tag{11.4.177}$$

Concerning the terminals we have for recall:

$$\cos^2(u)=\frac{r}{r_2}\qquad\cos^2(u_0)=\frac{r_1}{r_2}\tag{11.4.178}$$

So if r is equal to r_1 we write the bound as u_0 and if r equals r_2 then:

$$\cos^2(u)=\frac{r_2}{r_2}=1\Rightarrow u=0\tag{11.4.179}$$

Therefore:

$$\int\limits_{r_1}^{r_2}\sqrt{\left(\frac{1}{r}-\frac{1}{r_2}\right)}\mathrm{d}r=-2\sqrt{r_2}\int\limits_{u_0}^{0}\sin^2(u)\mathrm{d}u=2\sqrt{r_2}\int\limits_{0}^{u_0}\sin^2(u)\mathrm{d}u\tag{11.4.180}$$

We have seen in the section of Differential and Integral Calculus:

$$I_n=\int\sin^n(x)\mathrm{d}x=\frac{1}{n}\left(-\cos(x)\sin^{n-1}(x)+(n-1)I_{n-2}\right)\tag{11.4.181}$$

Therefore:

$$\begin{aligned}I_2&=\int\sin^2(x)\mathrm{d}x=\frac{1}{2}(-\cos(x)\sin(x)+I_0)\\I_0&=\int\sin^0(x)\mathrm{d}x=\int\mathrm{d}x=x\end{aligned}\tag{11.4.182}$$

Then:

$$I_2=\int\sin^2(x)\mathrm{d}x=\frac{1}{2}(-\cos(x)\sin(x)+I_0)=\frac{1}{2}(-\cos(x)\sin(x)+x)\tag{11.4.183}$$

What makes:

$$\begin{aligned}2\sqrt{r_2}\int\limits_{0}^{u_0}\sin^2(u)\mathrm{d}u=2\sqrt{r_2}\frac{1}{2}(-\cos(x)\sin(x)+x)\Big|_{u_0}^{0}&=\sqrt{r_2}\frac{1}{2}(-\cos(x)\sin(x)+x))\Big|_{u_0}^{0}\\&=\sqrt{r_2}\left[(-\cos(u_0)\sin(u_0)+u_0)-(\cos(0)\sin(0)+0)\right]\\&=\sqrt{r_2}\left[(-\cos(u_0)\sin(u_0)+u_0)\right]\end{aligned}\tag{11.4.184}$$

But, we also have (see section Trigonometry page 2519):

$$\sin(2u_0)=2\sin(u_0)\cos(u_0) \tag{11.4.185}$$

Therefore:

$$2\sqrt{r_2}\int\limits_0^{u_0}\sin^2(u)\mathrm{d}u=\sqrt{r_2}\left(-\frac{\sin(2u_0)}{2}+u_0\right)=\sqrt{r_2}\left(\frac{(2u_0-\sin(2u_0))}{2}\right) \tag{11.4.186}$$

Let us recall again that:

$$\cos^2(u_0)=\frac{r_1}{r_2}\Rightarrow u_0=\arccos\left(\sqrt{\frac{r_1}{r_2}}\right) \tag{11.4.187}$$

But, $r_2\gg r_1$, therefore, $r_1/r_2\cong 0$.

If we develop in Maclaurin series (see section Sequences and Series page 1703) to the first order:

$$\begin{gathered}u_0\cong\arccos(0)+\frac{1}{1!}\frac{\mathrm{d}\arccos\left(\sqrt{\frac{r_1}{r_2}}\right)_{r_1=0}}{\mathrm{d}r_1}r_1=\frac{\pi}{2}-\frac{1}{\sqrt{\frac{r_1}{r_2}}r_2\sqrt{1-\frac{r_1}{r_2}}}r_1\cong\frac{\pi}{2}-\frac{1}{\sqrt{\frac{r_1}{r_2}}}\frac{r_1}{r_2}\\=\frac{\pi}{2}-\sqrt{\frac{r_2}{r_1}\frac{r_1}{r_2}}\cdot\sqrt{\frac{r_2}{r_1}}\sqrt{\frac{r_1}{r_2}}=\frac{\pi}{2}-\sqrt{\frac{r_1}{r_2}}\end{gathered} \tag{11.4.188}$$

Therefore:

$$u_0\cong\frac{\pi}{2}-\sqrt{\frac{r_1}{r_2}} \tag{11.4.189}$$

We then have:

$$\begin{aligned}\sqrt{r_2}\left(\frac{(2u_0-\sin(2u_0))}{2}\right)&\cong\sqrt{r_2}\frac{\left(2\left(\frac{\pi}{2}-\sqrt{\frac{r_1}{r_2}}\right)-\sin\left(2\left(\frac{\pi}{2}-\sqrt{\frac{r_1}{r_2}}\right)\right)\right)}{2}\\&=\sqrt{r_2}\frac{\left(\pi-2\sqrt{\frac{r_1}{r_2}}-\sin\left(\pi-2\sqrt{\frac{r_1}{r_2}}\right)\right)}{2}=\sqrt{r_2}\left(\frac{\pi}{2}-\sqrt{\frac{r_1}{r_2}}-\frac{1}{2}\sin\left(\pi-2\sqrt{\frac{r_1}{r_2}}\right)\right)\\&=\sqrt{r_2}\left[\frac{\pi}{2}-\sqrt{\frac{r_1}{r_2}}-\frac{1}{2}\left(\sin(\pi)\cos\left(-2\sqrt{\frac{r_1}{r_2}}\right)+\cos(\pi)\sin\left(-2\sqrt{\frac{r_1}{r_2}}\right)\right)\right]\\&=\sqrt{r_2}\left[\frac{\pi}{2}-\sqrt{\frac{r_1}{r_2}}-\frac{1}{2}\left(\cos(\pi)\sin\left(-2\sqrt{\frac{r_1}{r_2}}\right)\right)\right]=\sqrt{r_2}\left[\frac{\pi}{2}-\sqrt{\frac{r_1}{r_2}}+\frac{1}{2}\sin\left(-2\sqrt{\frac{r_1}{r_2}}\right)\right]\end{aligned} \tag{11.4.190}$$

If we take the Maclaurin development to the first order:

$$\sin\left(-2\sqrt{\frac{r_1}{r_2}}\right)\cong-2\sqrt{\frac{r_1}{r_2}} \tag{11.4.191}$$

Therefore:

$$\begin{aligned}\sqrt{r_2}\left(\frac{(2u_0-\sin(2u_0))}{2}\right)&\cong\sqrt{r_2}\left[\frac{\pi}{2}-\sqrt{\frac{r_1}{r_2}}+\frac{1}{2}\sin\left(-2\sqrt{\frac{r_1}{r_2}}\right)\right]=\sqrt{r_2}\left[\frac{\pi}{2}-\sqrt{\frac{r_1}{r_2}}+\frac{1}{2}\left(-2\sqrt{\frac{r_1}{r_2}}\right)\right]\\&=\sqrt{r_2}\left[\frac{\pi}{2}-\sqrt{\frac{r_1}{r_2}}-\sqrt{\frac{r_1}{r_2}}\right]=\sqrt{r_2}\left[\frac{\pi}{2}-2\sqrt{\frac{r_1}{r_2}}\right]\end{aligned}\tag{11.4.192}$$

So all this to write finally:

$$T\propto\exp\left(-\frac{2\gamma}{\sqrt{r_2}}\int_{r_1}^{r_2}\sqrt{\left(\frac{1}{r}-\frac{1}{r_2}\right)}\mathrm{d}r\right)=\exp\left(-\frac{2\gamma}{\sqrt{r_2}}\sqrt{r_2}\left[\frac{\pi}{2}-2\sqrt{\frac{r_1}{r_2}}\right]\right)=\exp\left(-\gamma\left[\pi-4\sqrt{\frac{r_1}{r_2}}\right]\right)\tag{11.4.193}$$

Relation in which we can put again the coefficient of the exponential that we had determined in the section of Wave Quantum Physics. It is the exponential factor in the above relation which explains the great variation of the radioactive periods of the different nuclides, whereas the energy of the particles varies relatively little.

$$\boxed{T\propto\exp\left(-\frac{1}{\hbar}\sqrt{\frac{m4(\mathrm{Z}-2)q_e^2r_2}{4\pi\varepsilon_0}}\cdot\left(\pi-4\sqrt{\frac{r_1}{r_2}}\right)\right)}\tag{11.4.194}$$

Typically for the Uranium $^{238}\mathrm{U}$ nucleus, we can take the values from numerical (experimental) tables of the physical and universal constants that are in the previous relation to get a certain value of T (we will omit this numerical application for now since the numerical values in various tables are not all in agreement still in this early 121st century...).

Then, in the semi-classical approximation, the α nucleus has, in the potential well, a velocity of the order of:

$$v=\sqrt{\frac{2E_\alpha}{m}}\tag{11.4.195}$$

And it goes back and forth in a nucleus whose radius is of the order of r_1. These round trips therefore correspond to a certain number of oscillations per second. Indeed, if we denote by τ the average duration between of two successive shocks, we then have:

$$\tau=\frac{2r_1}{v}=\frac{2r_1}{\sqrt{\dfrac{2E_\alpha}{m}}}\tag{11.4.196}$$

Therefore the frequency is equal to:

$$f=\frac{1}{\tau}\tag{11.4.197}$$

Each time it has a probability T to cross the potential barrier. This probability per unit time is thus determined by:

$$\lambda\cong f\cdot T\tag{11.4.198}$$

and gives the disintegration constant λ of the isotope by α emission with a relatively large error if we make the calculation with the numerical values. Otherwise, the order of magnitude is by contrast exact what is not bad at all! Therefore the simplified academic approach above gives satisfactory results.

11.4.2.4.4 Beta- Disintegration (4)

Definition (#11.4.515): When a nucleus is unstable due to an overflow of neutrons (like Carbon 14 for example) it will not emit neutrons. On the other hand, it will have the ability to change one of its neutrons into a proton. During this transformation, to keep the total electrical charge of the system, an electron will be created. This transformation is named "β^- radioactivity" (because the electron has a negative charge in this disintegration).

The so-named β^- disintegration is therefore a characteristic of nuclei with an excess of neutrons. The isotopes concerned become more stable by transforming a neutron into a proton with emission of an electron β^- and a particle named "antineutrino" $\bar{\nu}$ which we will justify the presence further below.

We then have for the concerned neutron:

$$ {}_0^1\mathrm{n}^{+1/2} \rightarrow \mathrm{p}_+^{+1/2} + \beta_-^{+1/2} + \bar{\nu}_0^{-1/2} \tag{11.4.199}$$

We have put in right exponent the spin of the concerned particle and in right index the sign of the electric charge of the particle. Thus, we observe that the spin is a conserved quantity, as well as the electric charge.

We have for the concerned isotope:

$$ {}_Z^A\mathrm{X}_N \rightarrow {}_{Z+1}^{A}\mathrm{Y}_{N-1} + \beta^- + \bar{\nu} \tag{11.4.200}$$

✍**Example:**

The famous case of Radiocarbon dating:

$$ {}_6^{14}\mathrm{C} \rightarrow {}_7^{14}\mathrm{N} + \beta^- + \bar{\nu} \tag{11.4.201}$$

The energy released during the transmutation is calculated by means of the mass default:

$$ \mathrm{Q}_{\beta^-} = (M_X - M_Y - m_e)c^2 \tag{11.4.202}$$

By neglecting the binding energy of the electrons, we have:

$$ M_X = \mathrm{m}_X + \mathrm{Z}m_e \quad \text{and} \quad M_Y = \mathrm{m}_Y + (\mathrm{Z}+1)m_e \tag{11.4.203}$$

Caution!!! The Z in the equality of M_X is the same as that found in the expression of M_Y hence the $Z+1$.

We have then:

$$ \boxed{\mathrm{Q}_{\beta^-} = (m_X - m_Y)\cdot c^2} \tag{11.4.204}$$

Each pure β^- disintegration is characterized by a fixed decay energy Q. Since the kinetic energy of the nucleus is negligible by its mass compared to that of the combined electron and antineutrino, the released energy Q is shared between the kinetic energies of the β^- and $\bar{\nu}$. Since the mass of the antineutrino is very far below that of the electron, the kinetic energy of the antineutrino can also be neglected. However, the energy of the β^- is not fixed and can take any value between 0 and Q. We thus observe an energy spectrum unlike other types of radioactivity (because the electron may have variable kinetic energy).

The shape of the observed distributions makes it possible to give an average energy value to the β^- which is around:

$$\bar{E} \cong \frac{\mathrm{Q}_{\beta^-}}{3} = \frac{E_{\text{max}}}{3} \tag{11.4.205}$$

The existence of antineutrino was postulated in 11933 according to holocene calendar (three years after the neutrino that we will see below) by Wolfgang Pauli in order to satisfy the spin conservation that is axiomatically considered as a fundamental law. The introduction of such a strange particle was very controversial and not widely accepted (zero charge, non-zero spin, negligible mass) and it continues to pose some problems in the contemporary physics of the 121st century (holocene calendar).

Remark

Photons have spin 1 therefore according to spin conservation law a photon decaying into two photons does should not be possible as it would not conserve spin.

If we split a photon into two photons you end up with one of these combinations of spin :

- Spin -1 and spin -1 - does not total spin $+1$
- Spin -1 and spin $+1$ - does not total spin $+1$
- Spin $+1$ and spin -1 - does not total spin $+1$
- Spin $+1$ and spin -1 - does not total spin $+1$

None of them conserve spin so none of them are possible as far as we know.

Independently of the "electron neutrino" (denoted usually ν_e) accompanying the particles β^- and β^+ (the latter having several names "positron" or "positive electron") there exists a neutrino of the meson μ (muon) and a neutrino of the tau (tauon) that are respectively denoted: ν_μ and μ_τ not to confuse them. Subsequently, as we will not be confronted with the neutrino of meson or tau neutrinos, we will simply denote the electron neutrino ν instead of ν_e or of υ.

Remark

At the beginning of its discovery, the disintegration β^- was seen as a transmutation of the nucleus ... in small classes, even today, it is seen as the transformation of a neutron into a proton. In contemporary theories, it is seen as a the transformation of a quark d into quark u and it has led physicists to develop the theory of weak interaction to explain its origin.

Betavoltaic devices, also known as betavoltaic cells, are generators of electric current, in effect a form of battery, which use energy from a radioactive source emitting beta particles (electrons). A common source used is the hydrogen isotope, tritium. Unlike most nuclear power sources, which use nuclear radiation to generate heat, which then is used to generate electricity (thermoelectric and thermionic sources), betavoltaics use a non-thermal conversion process; converting the electron-hole pairs produced by the ionization trail of beta particles traversing a semiconductor.

Betavoltaic power sources (and the related technology of alphavoltaic power sources) are particularly well-suited to low-power electrical applications where long life of the energy source is needed, such as implantable medical devices or military and space applications.

The actual technology provide a source of continuous nanowatt-to-microwatt battery power that is resistant to a broad range of temperatures and other environmental conditions for extended periods of 20 or more years.

Figure 11.114: City Labs Nanotritium™ battery

For example, the amount of electricity is tied with half-life. For example, if ^{63}Ni has half-life of 100 years this means, that mole of Nickel (63 grams) will produce Avogadro/2 electrons during that 100 years. This means 10^{21} electrons per year and 10^{14} electrons per second.

This means up to 0.1 [mA] or electric current.

The total decay energy of ^{63}Ni is 67 [keV] and is approximately the maximum energy of electron. But, since the decay also produces neutrino the mean energy of electron is much smaller: 17 [keV] $(2.732 \cdot 10^{-15}$ [J]). This means that each electron has 17 kilovolts of electric tension.

So, the power of electricity from one mole of ^{63}Ni:

$$\begin{aligned} W = A \cdot E_{e^-} \cdot m &= {}^{63}\text{Ni specific activity} \cdot (2.732 \cdot 10^{-15}) \cdot 63 \\ &= (2.11 \cdot 10^{12}) \cdot (2.732 \cdot 10^{-15}) \cdot 63 \cong 0.36\,[\text{W}] \end{aligned} \tag{11.4.206}$$

This is not sufficient to provide iPhone 4 peak power consumption, which is about 1.5 [W]. So atomic batteries can actually not supersede conventional batteries, and serve for years.

Also, it must be noticed that the usage of radioactive batteries definitely require regulations for handling and probably would not be allowed inside a single unit for unrestricted civilian use. We know that when properly used betavoltaics are safe. But what about im-proper use / improper disposal / potential for abuse? At any rate, current perception of nuclear power by general public is not that good, so marketing nuclear batteries will present certain challenge. Also the price of Plutonium or Americanium batteries (that are superior to batteries in almost every way) have cost that limits them to micro power devices (one gram is worth almost $1,000$ dollars...).

11.4.2.4.5 Beta+ Disintegration (5)

Definition (#11.4.516): When a nucleus is unstable due to an overflow of protons it will not emit protons. On the other hand, it will have the ability to change one of its protons into a neutron. During this transformation, to keep the total electrical charge of the system there are two ways for this disintegration to occur:

- By capture of a negative electron and then we speak of "electronic capture radioactivity" (see further below)
- Or by emission of positive and then this transformation is named "β^+ radioactivity" (because the electron detected has a positive charge in this disintegration).

Therefore during a β^+ disintegration a proton is dissociated into a neutron, a positive electron ("positron") denoted β^+ and of a neutrino (which we will justify the presence a little lower).

This transformation has a ridiculously low probability since the inverse of the emission of an electron and an antineutrino would be the simultaneous capture of these two particles... and such a reunion of circumstances would be a miracle. To overcome this difficulty, the nucleus uses a quantum subterfuge: the emission of a particle is equivalent to the capture of its antiparticle. This joker then offers the aforementioned possibilities to the surplus nucleus in protons. Indeed, to carry out the inverse of the β^- disintegration, the solution consists for the nucleus to use the conservation of the energy and of the spin by emitting a positron and capturing in the quantum energy of vacuum (see section Quantum Field Theory page 5158) an antineutrino and to emit in exchange a neutrino.

We write this:

$$\mathrm{p}\rightarrow{}_0^1\mathrm{n}+\beta^++\nu \tag{11.4.207}$$

or:

$${}_Z^A\mathrm{X}_N\rightarrow{}_{Z-1}^{\;\;A}\mathrm{Y}_{N+1}+\beta^++\nu \tag{11.4.208}$$

The energy released during the transmutation is calculated by means of the mass default:

$$\mathrm{Q}_{\beta^+}=(\mathrm{M}_X-\mathrm{M}_Y-m_e)c^2 \tag{11.4.209}$$

By neglecting the binding energy of the electrons, we have:

$$M_X=\mathrm{m}_X+\mathrm{Z}m_e \quad \text{and} \quad M_Y=\mathrm{m}_Y+(\mathrm{Z}-1)m_e \tag{11.4.210}$$

Caution!!! The Z in the equality of M_X is the same as that found in the expression of M_X hence the $Z+1$.

We have then:

$$\boxed{\mathrm{Q}_{\beta+}=(m_X-m_Y-2m_e)c^2} \tag{11.4.211}$$

The β^+ disintegration can therefore take place only if $Q_{\beta+}\geq 0$, that is to say if:

$$(m_X-m_Y)\cdot c^2\geq 2m_ec^2=1.022\,[\mathrm{MeV}] \tag{11.4.212}$$

The mass energy of the electron $E=m_ec^2$ is important because it is the energy of one of the two photons resulting from an annihilation of a positron β^+ with an electron β^-.

As for the β^- disintegration, the energy of the β^+ is not fixed and can take any value between 0 and Q. We thus observe an energy spectrum.

Remark

A real particle-antiparticle pair can annihilate and generate two real photons. Quantum electrodynamics is time-reversal invariant, so the opposite process, in which two real photons disappear and create a real particle-antiparticle pair, is also possible. But this isn't named "photon annihilation"; it's named named "two-photon pair production". "Annihilation" is usually reserved to mean the transformation of a massive particle-antiparticle pair into massless particles.

11.4.2.4.6 Electronic capture (6)

Definition (#11.4.517): When a nucleus is unstable because of an overflow of protons with respect to neutrons, we know now that a favourable solution from the point of view of its energy is to transform one of its protons into a neutron, i.e. to realize the inverse of the β^- radioactivity. We saw just earlier that a possibility was for the nucleus via the disintegration β^+ to catch an antineutrino of the vacuum and to emit a positron (loss of its electric charge) and a neutrino. But it can also capture an electron from the electronic cloud (neutralizing its electrical charge) instead of emitting a positron, this is why we name this an "electronic capture" or "electron capture".

This will most often be an electron of layer K. What is written:

$${}^{A}_{Z}\mathrm{X}_N+e\rightarrow {}^{A}_{Z-1}\mathrm{Y}_{N+1}+\nu \tag{11.4.213}$$

The energy released during the transmutation is calculated by means of the mass default:

$$\mathrm{Q}_{\mathrm{EC}}=(M_X+m_e-M_Y)c^2 \tag{11.4.214}$$

assuming that the binding energy of the electron of the layer K and that of recoil of the nucleus are negligible.

It is therefore the electron neutrino that carries all the energy, hence the necessity that Wolfgang Pauli had to introduce this new particle (what had horrified him ...!). Since the captured electron occupies a precise energy level in the atom, the neutrinos resulting from the disintegration of an isotope by electronic capture have a determined energy and therefore have a discrete spectrum.

By neglecting the binding energy of electrons, we have:

$$M_X = m_X + Zm_e \quad \text{and} \quad M_Y = m_Y + (Z-1)m_e \tag{11.4.215}$$

Therefore:

$$\boxed{Q_{\text{EC}} = (m_X - m_Y)c^2} \tag{11.4.216}$$

The disintegration by electronic capture is in competition with the β^+ disintegration only if:

$$(m_X - m_Y)c^2 \geq 2m_e c^2 = 1.022\,[\text{MeV}] \tag{11.4.217}$$

in the case where:

$$(m_X - m_Y)c^2 < 2m_e c^2 = 1.022\,[\text{MeV}] \tag{11.4.218}$$

only the disintegration by electronic capture is possible.

However, the hole left by the absorbed electron requires a rearrangement of the atomic cloud and the emission of radiation.

Remark

Reaction of electron capture is how you turn White Dwarf star into a neutron star (see section Astrophysics page 5606).

11.4.2.4.7 Gamma emission (7)

Definition (#11.4.518): For the nucleus, the emission of electromagnetic radiation γ is a possibility of gaining stability. This emission generally follows a phenomenon of disintegration β^-, β^+, α or electronic capture. We can imagine that, in such types of disintegration, the topology of the nucleons in the nucleus is not ideal and that the rearrangement of the latter will be accompanied by a reduction of energy; The latter emitted in the form of one or more photons.

So we have a schema (β^-) disintegration:

$${}_{Z}^{A}\text{X}_N \rightarrow {}_{Z+1}^{A}\text{Y}_{N-1}^{m} + \beta^- + \bar{\nu} \tag{11.4.219}$$

then:

$${}_{Z+1}^{A}\text{Y}_{N-1}^{m} = {}_{Z+1}^{A}\text{Y}_{N-1} + \gamma \tag{11.4.220}$$

where the m means "metastable" or "isomer" (this last term is used when the emission of radiation takes place long time after disintegration).

Remark

"Isomer" means, in nuclear physics, that the nucleus is excited. It will de-energize with a period $T_{1/2}$. Generally the $T_{1/2}$ is extremely small and the photon(s) is (are) emitted immediately after the electron in the case of our example of a β^- disintegration. We then talk about "metastable state" or "isomer". It should be noted that these radioisotopes are particularly interesting in medical imaging.

The energy of the γ photon is equal to:

$$\boxed{Q_\gamma = (M_{Y^m} - M_Y)c^2} \tag{11.4.221}$$

Now let us suppose that a proton is confined in a box of width $L = 1.00 \cdot 10^{-14}$ [m] (a typical nuclear radius). If we assume that the proton confined in the nucleus can be modelled as a quantum particle in a box, all we need to do is to use the relation proven in the section of Wave Quantum Physics for an infinite potential wall box to find its energies E_1 and E_2:

$$E_n = n^2 \frac{\pi^2\hbar^2}{2mL^2} \tag{11.4.222}$$

Therefore the emitted photo has for energy:

$$\Delta E = h\nu = E_2 - E_1 = 2^2\frac{\pi^2\hbar^2}{2mL^2} - 1^2\frac{\pi^2\hbar^2}{2mL^2} = (4-1)\frac{\pi^2\hbar^2}{2mL^2} = 3\frac{\pi^2\hbar^2}{2mL^2} \cong 6.15\,[\text{MeV}] \tag{11.4.223}$$

Hence:

$$\nu = \frac{\Delta E}{h} \cong 1.49 \cdot 10^{21}\,[\text{Hz}] \tag{11.4.224}$$

This is the typical frequency of a gamma ray emitted by a nucleus. The energy of this photon is about 10 million times greater than that of a visible light photon!

11.4.2.4.8 Internal conversion (8)

Definition (#11.4.519): The "internal conversion (I.C.)" is a process related to the emission of a γ photon. Indeed, it is possible that the energy is transmitted directly to an electron of the electronic cloud, generally of the layer K, which is then ejected from the atom. This electron is named the "conversion electron". The place left in the electronic cloud is subsequently filled by an electron of the upper layers and so on. Thus, as in the case of an electronic capture decay process, there is a rearrangement of the electronic cloud characterized by the emission of X-rays characteristic by the element Y.

The energy transmitted is:

$$\boxed{E_{e^-} = E_\gamma - E_b} \tag{11.4.225}$$

with E_{e^-} being the kinetic energy of the emitted electron, E_γ the photon energy percutting the electron, E_b, the binding energy of the electron considered (K, L, M, ...).

The energy of the γ photon is transmitted directly to an electron that is ejected. The process is followed by the rearrangement of the electrons (an emission of X-rays will follow). The ejected electron is named "Auger electron" and sometimes the whole effect is named the "Auger effect".

The emission of a Auger electron is thus a process similar to the internal conversion process (IC), but the electromagnetic radiation does not come from a de-excitation of the nucleus (it is not a γ photon) but of a X-ray produced during the rearrangement of the electronic cloud. In a radioactive process, this electronic rearrangement can come either from an electronic capture (EC) or from an internal conversion (IC).

The ejected Auger electron comes mainly from an internal orbit and its energy is the characteristic energy of the X-ray minus its binding energy. The energy of the Auger electrons is therefore quite small (some [keV]) with respect to a β^- particle and these electrons are therefore often reabsorbed inside the source. The process of emission of an Auger electron is favoured for elements with low atomic number because of their low energies of electronic connection.

During a rearrangement of the electronic cloud such as the passage of an electron from the layer L to the layer K, the energy of the X-ray emitted will be equal to $E_\text{K}-E_\text{L}$. Since this energy difference is greater than the binding energy of another electron on layer L, the latter will then be emitted with the kinetic energy:

$$E_\text{Auger}=h\nu_{\text{L}\rightarrow\text{K}}-E_\text{L}=(E_\text{K}-E_\text{L})-E_\text{L}=E_\text{K}-2E_\text{L}>0=c^{te} \tag{11.4.226}$$

In turn, the 2 vacations left on layer L are filled with electrons from the upper layers. Fluorescence and Auger electron are then in competition. It is even possible that several Auger electrons are emitted during the de-excitation of the atom. This is named "Auger cascade" leaving the atom considered highly ionized, which can lead to the Coulomb explosion of the molecule of which it is a part.

To conclude on all these radioactive phenomena, let us indicate the order of magnitude of the radioactive periods of some natural and artificial elements:

Nuclide	**Radioactivity**	**Period**
Thorium 232	α	$\backsim 10^{10}$ years
Uranium 238	α	$\backsim 10^{9}$ years
Uranium 235	α	$\backsim 10^{8}$ years
Uranium 233	α	$\backsim 10^{5}$ years
Plutonium 239	α	$\backsim 10^{4}$ years
Plutonium 238	α	$\backsim 88$ years
Radium 226	α	$\backsim 10^{3}$ years
Curium 242	α	160 days
Potassium 40	β^-	$\backsim 10^{9}$ years
Carbon 14	β^-	$\backsim 10^{3}$ years
Tritium	β^-	21 years
Cobalt 60	β^-	$\backsim 5.3$ years
Iod 131	β^-	$\backsim 8$ days
Nitrogen 16	β^-	$\backsim 7.1$ seconds
Technetium 97	EC	$\backsim 10^{6}$ years
Cobalt 58	β^+	$\backsim 20$ minutes
Fluorine 18	β^+	$\backsim 110$ minutes

Table 11.17: **Amplitudes of the radioactive periods of a few nuclides**

Again, this is a quantum phenomenon that, in most interpretations of quantum mechanics, occurs spontaneously, that is, without cause.

11.4.3 Radiation protection

In nuclear physics (and also in "high energy astrophysics"), it is very important to know how the various α, γ, X-ray or neutron radiation interact with matter (roughly uncharged or charged radiation). This allows us to know how their kinetic energy is distributed or dissipated in the material they encounter along their path and to protect themselves in a suitable way.

"Radiation protection", sometimes known as "radiological protection", is defined by the International Atomic Energy Agency (IAEA) as "*The protection of people from harmful effects of exposure to ionizing radiation, and the means for achieving this*". The IAEA also states «*The accepted understanding of the term radiation protection is restricted to protection of people. Suggestions to extend the definition to include the protection of non-human species or the protection of the environment are controversial*».

Ionizing radiation is widely used in industry and medicine, and can present a significant health hazard. It causes microscopic damage to living tissue, which can result in skin burns and radiation sickness at high exposures (known as "tissue" or "deterministic" effects), and statistically elevated risks of cancer at low exposures ("stochastic effects").

Fundamental to radiation protection is the reduction of expected dose and the measurement of human dose uptake. For radiation protection and dosimetry assessment the International Committee on Radiation Protection (ICRP) and International Commission on Radiation Units and Measurements (ICRU) have published recommendations and data which is used to calculate the biological effects on the human body, and set regulatory and guidance limits.

Before investing this subject we must prove some relations and study some phenomena related to high energy radiations and behaviours of particles. So let us tackle this first!

11.4.3.1 Bethe formula

The "Bethe formula" describes the mean energy loss per distance travelled of swift charged particles (protons, alpha particles, atomic ions) traversing matter (or alternatively the stopping power of the material). For electrons the energy loss is slightly different due to their small mass (requiring relativistic corrections) and their indistinguishability, and since they suffer much larger losses by Bremsstrahlung, terms must be added to account for this. Fast charged particles moving through matter interact with the electrons of atoms in the material. The interaction excites or ionizes the atoms, leading to an energy loss of the travelling particle.

The non-relativistic version was found by Hans Bethe in 11930 (holocene calendar). The Bethe formula is sometimes named "Bethe-Bloch formula", but this is quite misleading.

A heavy charged particle having an energy of one or more MeV loses its energy mainly by collisions with the electrons cloud of atoms, electrons which appear to it as quasi-free. The process by which electrons are thus ejected during the passage of an ionizing particle is named "primary ionization electrons". An electron can escape if it receives an energy higher than its binding energy.

The maximum energy transfer E_{max} that can occur in a non-relativistic and elastic collision (where the system energy is conserved because there is by definition no heat - radiation - dissipation) is calculated simply by using the conservation principle of the linear momentum and energy:

Given M,v_M and m_e, v_e be the masses and velocities of the incident particle and the electron respectively. We assume that the electron is immobile in its orbit and that its initial velocity is zero ($v_e=0$). After the shock, we will assume that the incident particle will have transferred all its kinetic energy to the electron and will in turn find itself at rest such as $v'_M=0$.

Let us first consider the conservation of linear momentum:

$$Mv_M+m_ev_e=Mv'_M+m_ev'_e \tag{11.4.227}$$

The conservation of energy also allows us to write:

$$\frac{1}{2}Mv_M^2+\frac{1}{2}m_ev_e^2=\frac{1}{2}Mv_M'^2+\frac{1}{2}m_ev_e'^2 \tag{11.4.228}$$

Hence, after regrouping and simplification:

$$\begin{gathered}M\left(v_M-v'_M\right)=m_e\left(v'_e-v_e\right)\\ M\left(v_M^2-v_M'^2\right)=m_e\left(v_e'^2-v_e^2\right)\end{gathered} \tag{11.4.229}$$

Or otherwise written:

$$M\left(v_M-v'_M\right)=m_e\left(v'_e-v_e\right) \tag{11.4.230}$$

$$M\left(v_M+v'_M\right)\left(v_M-v'_M\right)=m_e\left(v'_e-v_e\right)\left(v'_e+v_e\right) \tag{11.4.231}$$

Then, after dividing the second equation by the first we have:

$$v_M+v'_M=v'_e+v_e \tag{11.4.232}$$

We then have the system:

$$\left.\begin{aligned}Mv_M+m_ev_e=Mv'_M+m_ev'_e\\ v'_M=v'_e+v_e-v_M\end{aligned}\right\}\Rightarrow m_ev'_e=Mv_M+m_ev_e-M(v'_e+v_e-v_M) \tag{11.4.233}$$

we then deduce the expression of the speed after the impact:

$$v'_e=\frac{v_e(m_e-M)+2Mv_M}{M+m_e} \tag{11.4.234}$$

relatively to our initial hypotheses ($v_e=0$, $v'_M=0$), we then have:

$$v'_e=\frac{2Mv_M}{M+m_e} \tag{11.4.235}$$

Let us manipulate this relation a bit:

$$\begin{gathered}v'_e=\dfrac{2Mv_M}{M+m_e}\Rightarrow\dfrac{1}{2}m_ev'_ev'_e=\dfrac{1}{2}m_ev'_e\dfrac{2Mv_M}{M+m_e}\Rightarrow E'^e_c=\dfrac{1}{2}Mv_Mv_M\dfrac{2m_ev'_e}{v_M(M+m_e)}\\ \Rightarrow E'^e_c=E^M_c\dfrac{2m_e}{(M+m_e)}\dfrac{v'_e}{v_M}=E^M_c\dfrac{2m_e}{(M+m_e)}\dfrac{\left(\dfrac{2Mv_M}{M+m_e}\right)}{v_M}=\dfrac{4Mm_e}{(M+m_e)^2}E^M_c\end{gathered}\tag{11.4.236}$$

For a heavy particle, with $M\gg m_e$ we can write:

$$_{\text{max}}E^e_c=\frac{4m_e}{M}\cdot E^M_c\tag{11.4.237}$$

An ionization can only occur if the $_{\text{max}}E^e_c$ is at least equal to the ionization threshold of the electron that we will denote by I_0 and whose calculation was seen during the study of the Bohr model (see section Corpuscular Quantum Physics page 4626).

The energy of the incident particle must therefore at least be equal to:

$$E^M_{\text{min}}=\frac{M\cdot I_0}{4m_e}\tag{11.4.238}$$

Thus, when passing through matter, the electrically charged body of charge $Z\cdot q_e$ and speed v_M yields its energy in numerous collisions with the electrons of the atoms encountered. The interaction is of the Coulomb type and each time a diffusion occurs. The recoil energy of the electron, assumed to be free, can be calculated accurately. To estimate the loss of energy, we will here approximate that the quantity of linear momentum transferred Δp is equal to the product of the interaction force at the distance r multiplied by the time necessary for the projectile to traverse the path $2r$. We have the Coulomb for F given for recall by (see section Electrostatics page 3968):

$$F=\frac{1}{4\pi\varepsilon_0}\cdot\frac{\mathrm{Z}q_e^2}{r^2}\tag{11.4.239}$$

and the linear momentum:

$$\Delta p=F\cdot t=\left(\frac{1}{4\pi\varepsilon_0}\cdot\frac{\mathrm{Z}q_e^2}{r^2}\right)\cdot\frac{2r}{v_M}=\frac{1}{4\pi\varepsilon_0}\frac{2\mathrm{Z}q_e^2}{rv_M}\tag{11.4.240}$$

The kinetic energy transferred to an electron of mass m_e will be:

$$\Delta E^e_c=\frac{1}{2}m_ev_M^2=\frac{1}{2}\frac{(\Delta p)^2}{m_e}=\frac{1}{(4\pi\varepsilon_0)^2}\cdot\frac{2\mathrm{Z}^2q_e^4}{r^2v_M^2m_e}\tag{11.4.241}$$

The total energy loss will be obtained by integrating on all the electrons encountered. At the distance range that is between r and $r+\mathrm{d}r$ of the trajectory and on the path of length $\mathrm{d}x$, there are:

$$\mathrm{d}N=N\cdot\mathrm{Z}'\cdot2\pi r\cdot\mathrm{d}r\cdot\mathrm{d}x\tag{11.4.242}$$

electrons, where N is the number of atoms of atomic number Z'p er unit volume. The loss of energy per unit of distance is therefore:

$$\begin{aligned}-\frac{\mathrm{d}E}{\mathrm{d}x}&=\int_{r_{\text{min}}}^{r_{\text{max}}}\Delta E^e_c\cdot\frac{\mathrm{d}N}{\mathrm{d}x}=\int_{r_{\text{min}}}^{r_{\text{max}}}\frac{1}{(4\pi\varepsilon_0)^2}\cdot\frac{2\mathrm{Z}^2q_e^4}{r^2v_M^2m_e}2\pi\mathrm{Z}'Nr\mathrm{d}r=\frac{4\pi N\mathrm{Z}'}{(4\pi\varepsilon_0)^2}\cdot\frac{\mathrm{Z}^2q_e^4}{m_ev_M^2}\int_{r_{\text{min}}}^{r_{\text{max}}}\frac{1}{r}\mathrm{d}r\\&=\frac{4\pi N\mathrm{Z}'}{(4\pi\varepsilon_0)^2}\cdot\frac{\mathrm{Z}^2q_e^4}{m_ev_M^2}\ln\left(\frac{r_{\text{max}}}{r_{\text{min}}}\right)\end{aligned}\tag{11.4.243}$$

The value of r_{min} is evaluated by noting that this "impact parameter" should corresponds in practice to the maximum energy transfer. Using the equations we have proved previously:

$$_{\max}\Delta E_c^e=\frac{1}{(4\pi\varepsilon_0)^2}\frac{2\mathrm{Z}^2q_e^4}{r_{\text{min}}^2v_M^2m_e}=\frac{4m_e}{M}\cdot E_c^M \tag{11.4.244}$$

With $E_c^M=\dfrac{1}{2}Mv_m^2$, we can get the parameter r_{min} by:

$$r_{\text{min}}^2=\frac{1}{(4\pi\varepsilon_0)^2}\frac{2\mathrm{Z}^2q_e^4}{v_M^2m_e}\frac{1}{2m_ev_M^2}=\frac{1}{(4\pi\varepsilon_0)^2}\frac{\mathrm{Z}^2q_e^4}{v_M^4m_e^2} \tag{11.4.245}$$

and we get:

$$r_{\text{min}}=\frac{1}{4\pi\varepsilon_0}\cdot\frac{\mathrm{Z}q_e^2}{v_M^2m_e} \tag{11.4.246}$$

When r becomes very big, the energy transfer is smaller than the mean ionization energy denoted $\bar{I}$ of the electrons and the process is no longer efficient. We must therefore have the following relation:

$$_{\min}\Delta E_c^e=\frac{1}{(4\pi\varepsilon_0)^2}\cdot\frac{2\mathrm{Z}^2q_e^4}{r_{\text{max}}^2v_M^2m_e}>\bar{I} \tag{11.4.247}$$

We derive a value for r_{max}:

$$r_{\text{max}}<\frac{1}{4\pi\varepsilon_0}\cdot\frac{\mathrm{Z}q_e^2}{v_M}\sqrt{\frac{2}{m_e\bar{I}}} \tag{11.4.248}$$

By replacing the values of r_{min} and r_{max} of the above relations into the equation:

$$-\frac{\mathrm{d}E}{\mathrm{d}x}=\frac{4\pi N\mathrm{Z}'}{(4\pi\varepsilon_0)^2}\frac{\mathrm{Z}^2q_e^4}{m_ev_M^2}\ln\left(\frac{r_{\text{max}}}{r_{\text{min}}}\right) \tag{11.4.249}$$

we get:

$$-\frac{\mathrm{d}E}{\mathrm{d}x}=\frac{4\pi N\mathrm{Z}'}{(4\pi\varepsilon_0)^2}\frac{\mathrm{Z}^2q_e^4}{m_ev_M^2}\ln\left(\sqrt{\frac{2m_ev^2}{\bar{I}}}\right) \tag{11.4.250}$$

A more rigorous quantum treatment would show that the root of the argument of the logarithm should be suppressed by taking into account the relativistic effects as well as the intrinsic properties of the electron (fine-structure constant). We would then obtain the following Bethe formula:

$$\boxed{-\frac{\mathrm{d}E}{\mathrm{d}x}=\frac{4\pi N\mathrm{Z}'}{(4\pi\varepsilon_0)^2}\frac{\mathrm{Z}^2q_e^4}{m_ev_M^2}\left[\ln\left(\sqrt{\frac{2m_ev^2}{I}}\right)-\ln(1-\beta^2)-\beta^2-\frac{c_k}{\mathrm{Z}}\right]} \tag{11.4.251}$$

where $\beta=v/c$ and c_k is a correction term that depends on energy and of Z when we take into account the complete structure of the nucleus (layered model) of the material.

Finally, we see that the loss of linear energy is proportional to the atomic number of the incident radiation and the penetrated matter. Thus, to come back on radio-protection..., protections composed of materials with high atomic numbers (high density) will have a high decelerating power and will be advantageous in radiation protection.

11.4.3.2 Compton scattering

The Compton effect is observed when a photon is scattered inelastically by a charged particle. In fact, the photon is absorbed and then re-emitted by the particle, thus giving up part of its energy. It is this transfer of energy that justifies the inelastic character of the diffusion.

Thus if the charged particle is an electron, this effect can take place indifferently on an electron of any electronic layer or even on a free electron. The energy of the photon and that of the electron depend on the direction of emission of these particles. Since this effect depends on the number of electrons available per target atom, the Compton diffusion probability increases linearly with the atomic number Z of the absorbent. But since this effect is in competition with the production of an electron-positron pair that we shall see later, the Compton effect is especially important at average energies and at average atomic numbers.

Let us recall that in the section of Special Relativity we have proved that:

$$E=mc^2=E_c+m_0c^2\Rightarrow E_c=mc^2-m_0c^2 \tag{11.4.252}$$

And let us recall that we have thus for the momentum of a photon:

$$E=mc^2\Rightarrow\frac{E}{c}=mc=p \tag{11.4.253}$$

and we have also proved in the Special Relativity section that, starting from the total energy, the linear momentum is given by:

$$\begin{gathered}E=c\sqrt{m_0^2c^2+p^2}\Rightarrow p^2=\frac{E^2}{c^2}-m_0^2c^2\Rightarrow p=\frac{1}{c}\sqrt{E^2-m_0^2c^4}=\frac{1}{c}\sqrt{(E_c+m_0c^2)^2-m_0^2c^4}\\=\frac{1}{c}\sqrt{E_c^2+2E_cm_0c^2+m_0^2c^4-m_0^2c^4}=\frac{1}{c}\sqrt{E_c^2+2E_cm_0c^2}=\frac{1}{c}\sqrt{E_c(E_c+2m_0c^2)}\end{gathered} \tag{11.4.254}$$

Hence the relation, which we shall use further below:

$$p^2c^2=E_c(E_c+2m_0c^2) \tag{11.4.255}$$

Before the interaction, photon-electron, we have (we roughly consider the electron as being at rest) for the total energy of the system:

$$h\nu_1+m_0c^2 \tag{11.4.256}$$

and after collision:

$$h\nu_2+\sqrt{m_0^2c^4+p^2c^2} \tag{11.4.257}$$

Conservation of energy leads us to write:

$$h\nu_1+m_0c^2=h\nu_2+\sqrt{m_0^2c^4+p^2c^2} \tag{11.4.258}$$

By considering only the kinetic energies, we neglect that of the electron before the shock:

$$h\nu_1=E_e+h\nu_2=(mc^2-m_0c^2)+h\nu_2 \tag{11.4.259}$$

Either the figure below:

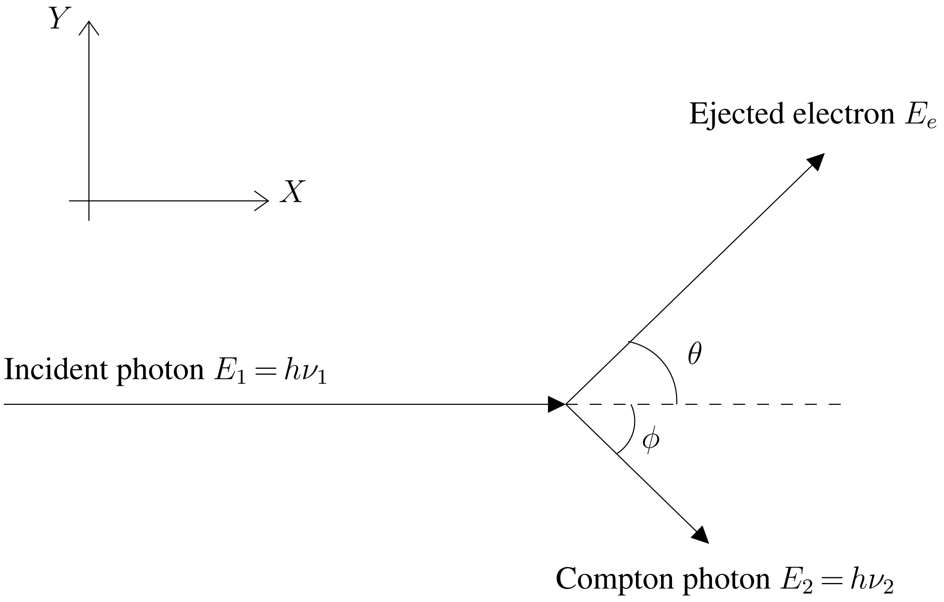

Figure 11.115: **Simplified illustration of the Compton effect**

The conservation of the linear momentum gives us according to the x-axis:

$$\frac{E_1}{c} = \frac{E_2}{c}\cos(\phi) + p_e\cos(\theta) \Leftrightarrow p_e\cos(\theta) = \frac{E_1}{c} - \frac{E_2}{c}\cos(\phi) \tag{11.4.260}$$

and according to the y-axis:

$$0 = \frac{E_2}{c}\sin(\phi) - p_e\sin(\theta) \Leftrightarrow p_e\sin(\theta) = \frac{E_2}{c}\sin(\phi) \tag{11.4.261}$$

The sum of these two relations squared gives us the total linear momentum:

$$\begin{gathered}p_e^2\cos^2(\theta) + p_e^2\sin^2(\theta) = \left(\frac{E_1}{c} - \frac{E_2}{c}\cos(\phi)\right)^2 + \left(\frac{E_2}{c}\sin(\phi)\right)^2\\ \Rightarrow p_e^2 = \frac{E_1^2}{c^2} - 2\frac{E_1E_2}{c^2}\cos(\phi) + \frac{E_2^2}{c^2}\cos^2(\phi) + \frac{E_2^2}{c^2}\sin^2(\phi) = \frac{E_1^2}{c^2} - 2\frac{E_1E_2}{c^2}\cos(\phi) + \frac{E_2^2}{c^2}\\ \Rightarrow p_e^2c^2 = E_1^2 + E_2^2 - 2E_1E_2\cos(\phi)\end{gathered} \tag{11.4.262}$$

Then by substituting $p_e^2c^2$:

$$E_{c,e}(E_{c,e} + 2m_0c^2) = E_1^2 + E_2^2 - 2E_1E_2\cos(\phi) \tag{11.4.263}$$

and as $E_{c,e} = E_1 - E_2$:

$$E_2 = \frac{E_1}{1 + \dfrac{E_1}{m_0c^2}(1-\cos(\phi))} \tag{11.4.264}$$

When the energy of the photon is high enough, that is $E_1 \gg m_0c^2$, that of the scattered photon tends to a limit given by (see l'Hôpital's rule in the section of Differential and Integral Calculus at page 1461):

$$\lim_{h\nu_1 \gg m_0c^2} h\nu_1 = \lim_{k\nu_1 \gg m_0c^2} E_2 = \frac{m_0c^2}{(1-\cos(\phi))} \tag{11.4.265}$$

The energy acquired by the Compton electron is finally equal to:

$$E_e = E_1 - E_2 = \frac{\dfrac{E_1^2}{m_0c^2}(1-\cos(\phi))}{1+\dfrac{E_1}{m_0c^2}(1-\cos(\phi))} \tag{11.4.266}$$

It is interesting to notice that we can not have $E_e = E_1$. Indeed this would suppose that:

$$E_2 = \frac{E_1}{1+\dfrac{E_1}{m_0c^2}(1-\cos(\phi))} = 0 \tag{11.4.267}$$

and we see well that in fact, whatever the value of ϕ, we always have $E_2 \neq 0$.

The frequency of the scattered photon is lower than that of the incident photon because its energy E_2 is always lower and hence its wavelength λ_2 larger. Therefore:

$$\Delta\lambda = \lambda_2 - \lambda_1 = c\left(\frac{1}{\nu_2}-\frac{1}{\nu_1}\right) = hc\left(\frac{1}{E_2}-\frac{1}{E_1}\right) = \frac{hc}{E_1}\left(\frac{E_1}{E_2}-1\right) \tag{11.4.268}$$

and since:

$$E_2 = \frac{E_1}{1+\dfrac{E_1}{m_0c^2}(1-\cos(\phi))} \tag{11.4.269}$$

We have:

$$\Delta\lambda = \frac{hc}{E_1}\left(1+\frac{E_1}{m_0c^2}(1-\cos(\phi))-1\right) = \frac{hc}{m_0c^2}(1-\cos(\phi)) \tag{11.4.270}$$

That is:

$$\boxed{\Delta\lambda = \frac{h}{m_0c}(1-\cos(\phi))} \tag{11.4.271}$$

which is also written using the definition of the Planck constant and the usual trigonometric relations:

$$\boxed{\Delta\lambda = \frac{4\pi\hbar}{mc}\sin^2\left(\frac{\phi}{2}\right)} \tag{11.4.272}$$

We name the factor $\dfrac{h}{m_0c^2}$ the "Compton wavelength" and its value is equal to:

$$\lambda_C = 2.426\cdot 10^{-12}\;[\text{m}] \tag{11.4.273}$$

Notice that if the angle ϕ is equal to zero, then the wavelength variation is zero and if the angle ϕ is equal to 180° (π [rad]) then the variation of the incident photon wavelength is twice the length of the Compton's wavelength!

Figure 11.116: Compton scattering

Remark

One way to think of Compton scattering in the point of view of Quantum Field Theory is that the photon forms a virtual $e^- e^+$ pair, the virtual positron annihilates the original "real" electron giving off a photon and the "virtual" electron continues out of the Feynman diagram as the scattered "real" electron. As far as we know, only QFT permits us to calculate the cross differential section of the Compton scattering!

Let us prove now a very interesting case! A free electron absorb a photon!

This is because energy and momentum cannot be simultaneously conserved if a free electron were to absorb a photon. If the electron is bound to an atom then the atom itself is able to act as a third body repository of energy and momentum.

To prove that theoretically let us write down the conservation of momentum when a photon (ν) interacts with a free electron, assuming that it were absorbed:

$$p_1 + p_\nu = p_2 \tag{11.4.274}$$

where p_1 and p_2 are the momentum of the electron before and after the interaction. Conservation of energy gives us:

$$\sqrt{(p_1^2 c^2 + m_e^2 c^4)} + p_\nu c = \sqrt{(p_2^2 c^2 + m_e^2 c^4)} \tag{11.4.275}$$

Squaring the above equation and substituting for p_ν from equation we have:

$$p_1^2 c^2 + m_e^2 c^4 + 2\left(p_2 - p_1\right)\sqrt{(p_1^2 c^2 + m_e^2 c^4)} + \left(p_2 - p_1\right)^2 c^2 = p_2^2 c^2 + m_e^2 c^4 \tag{11.4.276}$$

After rearranging:

$$(p_2-p_1)^2c^2-\left(p_2^2-p_1^2\right)c^2+2\,(p_2-p_1)\,c\sqrt{\left(p_1^2c^2+m_e^2c^4\right)}=0 \tag{11.4.277}$$

Clearly $p_2-p_1=0$ is a solution to this equation, but cannot be possible if the photon has nonzero momentum. Dividing through by this solution we are left with:

$$\sqrt{\left(p_1^2c^2+m_e^2c^4\right)}-p_1c=0 \tag{11.4.278}$$

This solution is also impossible if the electron has non-zero rest mass (which it does). We conclude therefore that a free electron cannot absorb a photon because energy and momentum cannot simultaneously be conserved.

The above proof assumes a linear interaction. In general $\vec{p}_\nu,\vec{p}_1$ and $\vec{p}_2$ would not be aligned. However we can always transform to a frame of reference where the electron is initially at rest so that $\vec{p}_1=0$ and then the momentum of the photon and the momentum of the electron after the interaction would have to be equal. This then leads to the nonsensical result that either $p_2=0$ or $m_ec^2=0$.

11.4.3.2.1 Thomson scattering

Thomson scattering is the elastic scattering of electromagnetic radiation by a free charged particle, as described by classical electromagnetism. It is just the low-energy limit of Compton scattering: the particle kinetic energy and photon frequency do not change as a result of the scattering. This limit is valid as long as the photon energy is much less than the mass energy of the particle: $h\nu\ll m_ec^2$, or equivalently, if the wavelength of the light is much greater than the Compton wavelength of the particle.

First consider scattering of (classical) electromagnetic waves by free electrons, named "Thomson scattering". The electron experiences a force due to the incident electric field:

$$E=\hat{E}e^{\mathrm{i}(\vec{k}\circ\vec{r}-\omega t)} \tag{11.4.279}$$

The equation of motion for the charged particle is:

$$F=ma=m\ddot{r}=-eE \tag{11.4.280}$$

We recall that in the dipole approximation (valid since the wavelength of light is large compared to the scatterer) the power emitted per unit solid angle is (see section Electrodynamics page 4163):

$$\dfrac{\mathrm{d}P}{\mathrm{d}\Omega}=\dfrac{e^2}{16\pi^2\varepsilon_0c^3}\langle a^2\rangle\sin^2(\theta) \tag{11.4.281}$$

where $\langle a^2\rangle$ represents the "time-averaged squared acceleration". The equation of motion gives the acceleration directly and we assume that it is equal to the time averaged squared acceleration such that:

$$a^2=\dfrac{e^2}{2m^2}\hat{E}^2:=\langle a^2\rangle \tag{11.4.282}$$

This yields, upon rearranging:

$$\frac{\mathrm{d}P}{\mathrm{d}\Omega}=\left(\frac{e^2}{4\pi\varepsilon_0 mc^2}\right)^2\frac{\varepsilon_0 c\hat{E}^2}{2}\sin^2(\theta) \tag{11.4.283}$$

The term in the brackets is known as the "classical electron radius":

$$r_c=\frac{e^2}{4\pi\varepsilon_0 mc^2}=2.8\cdot 10^{-15}\,[\mathrm{m}] \tag{11.4.284}$$

Now recall that the time-averaged Poynting vector which is the incident energy per unit area per unit time is (see section Electrodynamics page 4156):

$$\bar{S}=\frac{\hat{E}^2}{2\mu_0 c}=\frac{c\varepsilon_0\hat{E}^2}{2} \tag{11.4.285}$$

We can astutely fall back on the "differential scattering cross section" define earlier above by using dimensional analysis:

$$\frac{\mathrm{d}\sigma}{\mathrm{d}\Omega}=\frac{\frac{\mathrm{d}P}{\mathrm{d}\Omega}}{\bar{S}} \tag{11.4.286}$$

and is the area of the wavefront which delivers the same power as is scattered into a given solid angle $\mathrm{d}\Omega$. So we get after simplification:

$$\frac{\mathrm{d}\sigma}{\mathrm{d}\Omega}=\left(\frac{e^2}{4\pi\varepsilon_0 mc^2}\right)^2\sin^2(\theta)=r_c^2\sin^2(\theta) \tag{11.4.287}$$

The total cross section is obtained by integrating over $\mathrm{d}\Omega$:

$$\sigma=r_c^2\int\sin^2(\theta)\mathrm{d}\Omega \tag{11.4.288}$$

But from the section Trigonometry we know that:

$$\mathrm{d}\Omega=\sin(\theta)\mathrm{d}\theta\mathrm{d}\phi \tag{11.4.289}$$

Therefore (identically as the integral we did in the Trigonometry section):

$$\begin{aligned}\sigma&=r_c\int\limits_0^{2\pi}\mathrm{d}\phi\int\limits_0^{\pi}\sin^3(\theta)\mathrm{d}\theta=2\pi r_c^2\int\limits_0^{\pi}\sin^3(\theta)\mathrm{d}\theta\\&=2\pi r_c^2\left(-\frac{1}{3}\cos(x)\sin^2(x)-\frac{2}{3}\cos(x)\right)\Bigg|_0^{\pi}=2\pi r_c^2\left[-\frac{2}{3}\cdot(-1)-\left(-\frac{2}{3}\cdot(1)\right)\right]\\&=2\pi r_c^2\frac{4}{3}\end{aligned} \tag{11.4.290}$$

Therefore:

$$\boxed{\sigma_T=\frac{8\pi}{3}r_c^2=\frac{8\pi}{3}\left(\frac{e^2}{4\pi\varepsilon_0 mc^2}\right)^2\cong 6.652\cdot 10^{-29}\,[\mathrm{m}^2]} \tag{11.4.291}$$

This is known as the "classical Thomson cross section" or also "electron Thomson cross section".

Therefore the fraction of photons scattered at distance r is the obviously given by (this term is dimensionless!):

$$f_T = \frac{\sigma_T}{4\pi r^2} \tag{11.4.292}$$

The classical Thomson scattering formula is known to be in disagreement with experiment by the early 11920s (holocene calendar). The Klein-Nishina formula based on Quantum Electrodynamics (QED) agreed perfectly with the available experiments in the late 11920s (holocene calendar). However at ultra relativistic energies it looked wrong. It was not until many years later the difference was shown to be due to the production of electron/positron pairs, with the positron annihilating into some other electron, and to Bremsstrahlung.

Remark

Thomson scattering is important on very different scales in Astronomy. For example: At high temperatures, Thomson scattering can dominate the photon diffusion in a star and thus determines the energy flux making its way out of the star. At the epoch of the Universe recombination ($z \cong 1,100$), Thomson scattering caused the high opacity of the plasma. The effects of Thomson scattering are, for example, visible in the diffusion damping of Baryon Acoustic Oscillations. For high l-moments ($l \geq 1,000$), Thomson scattering set the length over which photons could diffuse. This directly determines the damping of small scales (high moments) as inhomogeneities can be levelled out by photons.

11.4.3.3 Rayleigh scattering

"Rayleigh scattering" is the (dominantly) elastic scattering of light or other electromagnetic radiation by particles much smaller than the wavelength of the radiation. Rayleigh scattering does not change the state of material and is, hence, a parametric process. The particles may be individual atoms or molecules. It can occur when light travels through transparent solids and liquids, but is most prominently seen in gases. Rayleigh scattering results from the electric polarizability of the particles. The oscillating electric field of a light wave acts on the charges within a particle, causing them to move at the same frequency. The particle therefore becomes a small radiating dipole whose radiation we see as scattered light.

The strong wavelength dependence of the scattering (λ^{-4}) means that shorter (blue) wavelengths are scattered more strongly than longer (red) wavelengths. This results in the indirect blue light coming from all regions of the sky. Rayleigh scattering is a good approximation of the manner in which light scattering occurs within various media for which scattering particles have a small size (parameter).

Now consider scattering from a harmonically bound electron excited by a harmonic force. In the simplest approximation it is described by the equation of motion given below (see section Music Mathematics page 8224):

$$\ddot{r} + \gamma\dot{r} + \omega_0^2 r = -\frac{q_e}{m_e}E \tag{11.4.293}$$

But in the case of Rayleigh scattering, physicist like to change a sign in front of one of the constant (it permits some simplifications later below):

$$\ddot{r}-\gamma\dot{r}+\omega_0^2 r=-\frac{q_e}{m_e}E \tag{11.4.294}$$

Keep in mind that an accelerating electron will radiate causing the oscillator to lose energy as a damped oscillator where γ is the damping rate due to radiation losses.

Remark

A simple model for the dielectric properties of a material is obtained by considering the motion of a bound electron in the presence of an applied electric field. As the electric field tries to separate the electron from the positively charged nucleus, it generates an electric dipole moment. Averaging this dipole moment over the volume of the material gives rise to a macroscopic dipole moment per unit volume. The model is described exactly by the same differential equation and solutions as we will see at page 4240.

The limit $\omega_0=0$ corresponds to unbound electrons and describes the case of good conductors. The frictional term $y\dot{x}$ arises from collisions that tend to slow down the electron. The parameter y is a measure of the rate of collisions per unit time, and therefore, $\tau=1/\gamma$ will represent the mean-time between collisions.

In a typical conductor, τ is of the order of 10^{-14} seconds, for example, for copper, $\tau=2.4\cdot10^{-14}\,[\text{s}]$ and $y=4.1\cdot10^{13}\,[\text{s}^{-1}]$. The case of a tenuous, collisionless, plasma can be obtained in the limit $\gamma=0$. Thus, the above simple model can describe the following cases:

a. Dielectrics, $\omega_0\neq0,\gamma\neq0$

b. Conductors, $\omega_0=0,\gamma\neq0$

c. Collisionless Plasmas, $\omega_0=0,\gamma=0$

The basic idea of this model is that the applied electric field tends to separate positive from negative charges, thus, creating an electric dipole moment. In this sense, the model contains the basic features of other types of polarization in materials, such as Ionic/molecular polarization arising from the separation of positive and negative ions by the applied field, or polar materials that have a permanent dipole moment.

We will try the complex function, $r(t)=Ae^{\mathrm{i}(\omega t+\varphi)}$, with A a real number, $r(t)$ cycling at the same frequency as the driving force. We can always take the amplitude A to be real: that is not a restriction, since we have added the adjustable phase factor $e^{\mathrm{i}\varphi}$. Physically, this factor allows the solution to differ from the driver in phase, which it usually does. If we succeed in finding an $r(t)$ that satisfies the equation, the real parts of the two sides of the equation must be equal.

Remark

If $r(t)=Ae^{\mathrm{i}(\omega t+\varphi)}$ is a solution to the equation with the complex driving force, $F_0e^{\mathrm{i}\omega t}$, its real part (and where $F_0=-q_e/mE_0$), $A\cos(\omega t+\varphi)$, will be a solution to the equation with the real physical driving force, $F_0\cos(\omega t)$.

It's very easy to check that $r(t)=Ae^{\mathrm{i}(\omega t+\varphi)}$ is a solution to the equation, with the right A and φ. Just plug it in and see what happens. The differentiations are simple, giving:

$$-\omega^2 Ae^{\mathrm{i}(\omega t+\varphi)}-\mathrm{i}\gamma\omega Ae^{\mathrm{i}(\omega t+\varphi)}+\omega_0 Ae^{\mathrm{i}(\omega t+\varphi)}=F_0e^{\mathrm{i}\omega t} \tag{11.4.295}$$

To nail down A and φ, we begin by cancelling out the common factor $e^{\mathrm{i}\omega t}$, then shift the $e^{\mathrm{i}\varphi}$ to the other side to find:

$$A=\frac{F_0e^{-\mathrm{i}\varphi}}{\omega_0^2-\omega^2-\mathrm{i}\gamma\omega} \tag{11.4.296}$$

Therefore:

$$r=\frac{-q_e/m_e}{\omega_0^2-\mathrm{i}\gamma\omega-\omega^2}E \tag{11.4.297}$$

or in vector form:

$$\vec{r}=\frac{-q_e/m_e}{\omega_0^2-\mathrm{i}\gamma\omega-\omega^2}\vec{E}=\frac{-q_e/m_e}{(\omega_0^2-\omega^2)-\mathrm{i}\gamma\omega}\vec{E} \tag{11.4.298}$$

Let us recall, exactly as we did just earlier for the Thomson scattering, that in the dipole approximation (valid since the wavelength of light is large compared to the scatterer) the power emitted per unit solid angle is (see section Electrodynamics page 4163):

$$\frac{\mathrm{d}P}{\mathrm{d}\Omega}=\frac{q_e^2}{16\pi^2\varepsilon_0c^3}\langle a^2\rangle\sin^2(\theta) \tag{11.4.299}$$

where $\langle a^2\rangle$ represents the "time-averaged squared acceleration".

Before calculating the time-average acceleration, let us first take the module of the complex number. For this remember that:

$$\left|\frac{1}{z}\right|=\frac{1}{|z|}=\frac{1}{|a+\mathrm{i}b|}=\frac{1}{\sqrt{a^2+b^2}}\quad\text{with}\quad z\neq 0 \tag{11.4.300}$$

Therefore:

$$|\vec{r}|=\left|\frac{-q_e/m_e}{(\omega_0^2-\omega^2)-\mathrm{i}\gamma\omega}\vec{E}\right|=\frac{-q_e/m_e}{\sqrt{(\omega_0^2-\omega^2)^2+\gamma^2\omega^2}}\vec{E}=\frac{-q_e/m_e}{\sqrt{(\omega^2-\omega_0^2)^2+\gamma^2\omega^2}}\vec{E} \tag{11.4.301}$$

Now we can calculate the time-averaged squared acceleration is[37]:

$$\begin{aligned}\langle|a|^2\rangle=\langle|\ddot{\vec{r}}|\cdot|\ddot{\vec{r}}|\rangle&=\left[\sqrt{\frac{1}{T}\int\limits_0^T\left(\frac{-\omega^2q_e/m_e}{\sqrt{(\omega^2-\omega_0^2)^2+\gamma^2\omega^2}}\vec{E}\right)^2\mathrm{d}t}\,\right]^2=\left[\frac{1}{\sqrt{2}}\left(\frac{\omega^2q_e/m_e}{\sqrt{(\omega^2-\omega_0^2)^2+\gamma^2\omega^2}}\right)\right]^2\\&=\frac{q_e^2}{2m_e^2}\left(\frac{\omega^4}{(\omega^2-\omega_0^2)^2+\gamma^2\omega^2}\right)\end{aligned} \tag{11.4.302}$$

---

[37] To see where the factor $1/2$ - i.e. the square of $1/\sqrt{2}$ - comes from, see our study of the average power at...

Thus the scattering cross-section known as the "Rayleigh scattering cross section" is given by:

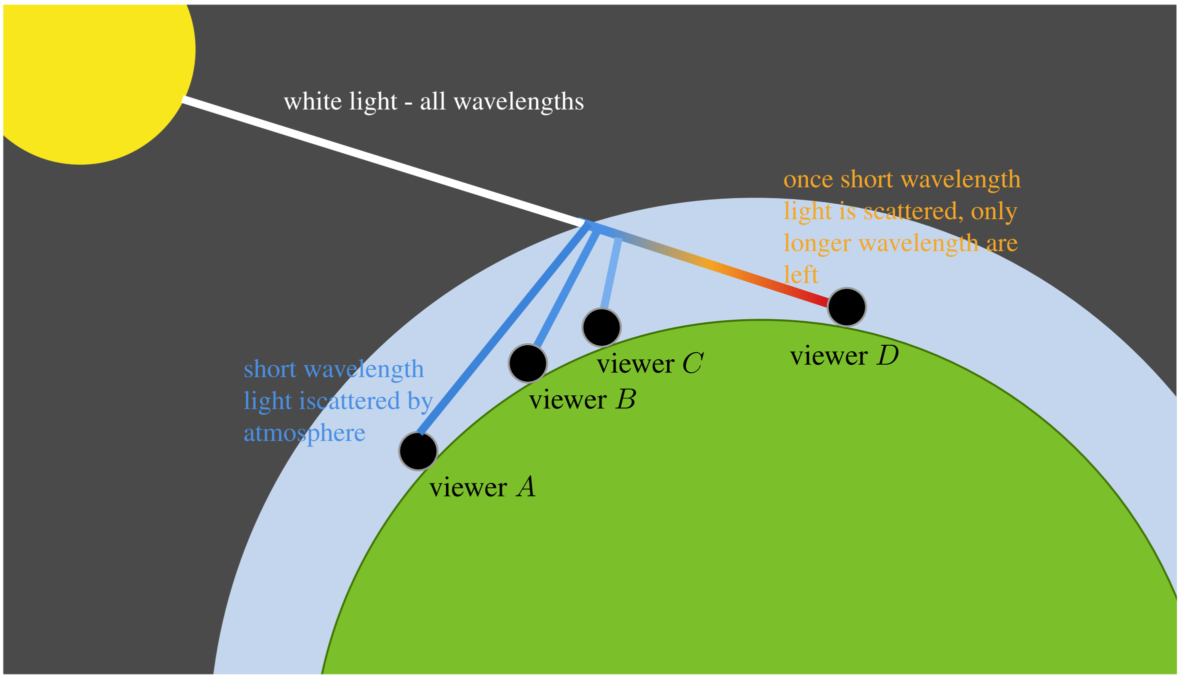
$$\sigma_R = \frac{q_e^2}{2m_e^2}\left(\frac{\omega^4}{(\omega^2-\omega_0^2)^2+\gamma^2\omega^2}\right) \quad (11.4.303)$$

For strong binding (i.e., $\omega_0 \gg \omega$), we have:

$$\boxed{\sigma_R \cong \frac{q_e^2}{2m_e^2}\left(\frac{\omega}{\omega_0}\right)^4 = \frac{q_e^2}{2m_e^2}\left(\frac{\lambda_0}{\lambda}\right)^4 \propto \lambda^{-4}} \quad (11.4.304)$$

So the total scattering cross section is given by the inverse fourth power of the wavelength and this was derived by Rayleigh.

This strong wavelength dependence makes short wavelength light (blues and violets) scatter more than long wavelength light (reds and yellows). This effect explains why the sky is blue. Short wavelength or blue light scatters the most.



white light - all wavelengths
once short wavelength light is scattered, only longer wavelength are left
short wavelength light iscattered by atmosphere
viewer A
viewer B
viewer C
viewer D

Figure 11.117: A single ray of light from the Sun and how it might be scattered and seen as different colours to viewers at different positions on Earth (source: Ask a scientist)

This formula is valid for scattering of light by air molecules (N_2, O_2) and shows that air molecules scatter the shorter wavelengths (blue) preferentially thus leading to blueness of the sky.

Rayleigh scattering is scattering from polarizable entities. The incident light induces a dipole moment, which re-radiates. Thomson scattering is scattering from free unbound charged "unpolarizable" particles.

From the perspective of radiation oncology (i.e. higher energy) physics, here is the main difference, in a few words.

- Rayleigh scattering is the elastic scattering of a photon off an entire atom.

- Thomson scattering is the elastic scattering of a photon off a single unbound electron.

Both are more likely to happen at lower energies. In particular, Rayleigh scattering cross section depends on the inverse square of initial photon energy. Thomson scattering cross section has a more complicated energy dependence, with many terms (find it in many textbooks), generally stronger than inverse square.

According to Rayleigh scattering, we should observe a violet sky. In order to understand why we perceive the sky to be blue, we should take into consideration two other phenomena:

- The solar radiation spectrum has its peak in the blue wavelengths and it drops for the violet wavelengths.
- In addition, our eyes are composed of three types of cones detecting red, green and blue colors. Thus, if we look at the sensitivity of the blue cones as a function of the wavelength, we will see that this sensitivity is much higher for the blue color than for violet.

Rayleigh scattering also explains why the Moon turns red during a total lunar eclipse because of refraction by the Earth's atmosphere. Bluish components of sunlight is scatterred more, and more of its reddish components reaches the Moon's surface.

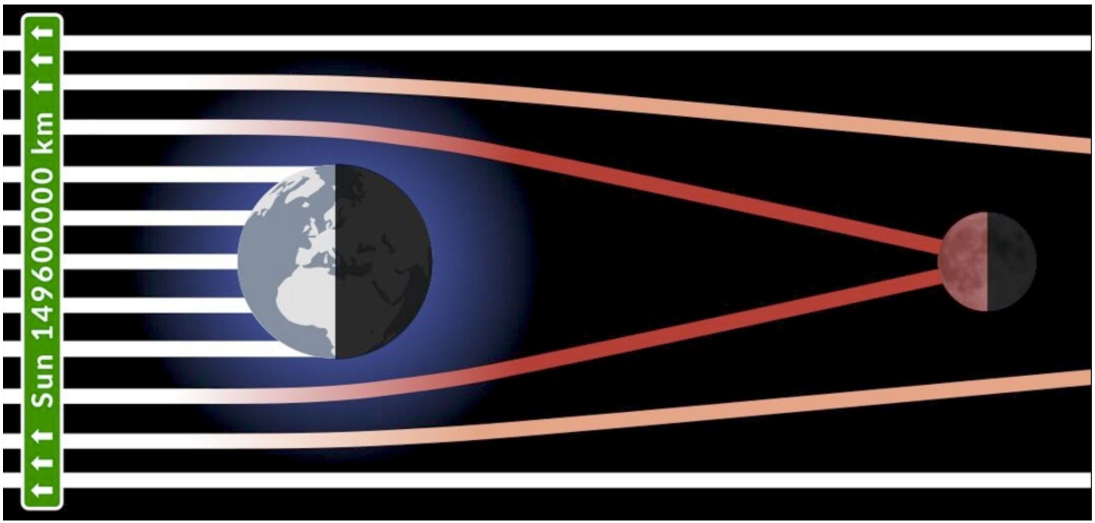


Figure 11.118: **Rayleigh scattering and Moon color during lunar eclipse (source: FlatEarth.ws/blood-moon)**

11.4.3.4 Photoelectric effect

The photoelectric effect is the ejection of electrons (the named "photoelectrons") from the surface of various metals exposed to radiation energy. This radiation can come from the rearrangement of the nucleus of the atom as well as from an external radiation.

Moreover, it was by quantitative measurements of the photoelectric effect that Albert Einstein proposed to test the quantum theory of light (Wave Quantum theory) and therefore the theoretical explanation that bring him to receive Nobel prize of Physics.

Let us first describe the experiment: the emission of electrons by a metal does not contradict the electromagnetic theory of light. If we consider a uniform beam, its energy is uniformly distributed over the entire wave front. The more intense the light is, the greater the amplitudes of the electric and magnetic fields at each point of the wavefront and the greater the energy per second transmitted by the wave is. These fields exert forces on the electrons in the metal and can even tear them from its surface.

Here is the experience set up:

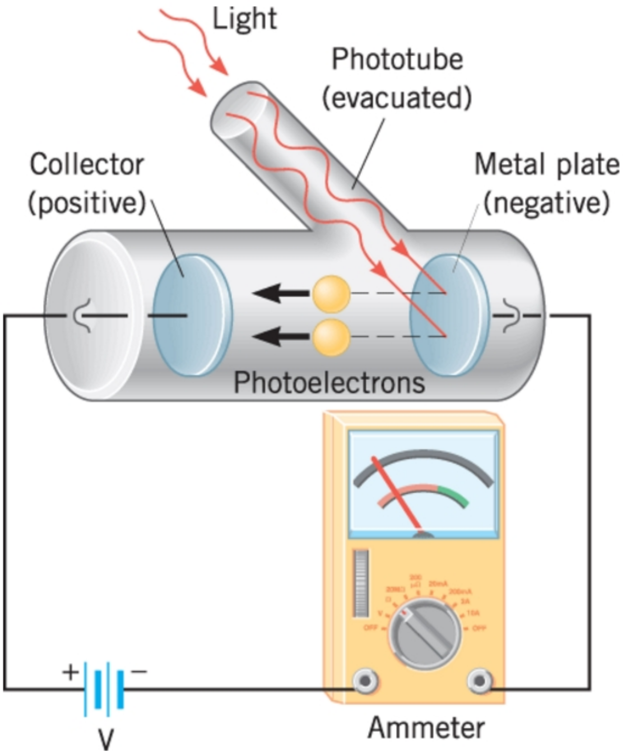

Figure 11.119: **Experiment for measuring the photoelectric effect (source: ?)**

If the collecting anode is at a positive potential relative to the emitting cathode, the photoelectrons traverse the tube and constitute the current measured by the ammeter. We then observe experimentally a proportionality between the intensity of the incident beam and the current. However, at least three problems persist between the theoretical model and the experimental observation:

1. The wave aspect of light is not suitable for explaining the time required to absorb the extraction energy.

   Indeed, let us consider a 100 [W] lamp with a 15% luminous efficiency placed at 0.5 [m] of a potassium-coated plate (chemical symbol of potassium is K) have a minimum extraction energy of 2.25 [eV] assuming a diameter of $1\cdot 10^{-10}$ [m] for the Potassium atom.

   We then have:

$$I=\dfrac{P\cdot\eta}{S_{\text{radiation}}}=\dfrac{100\cdot 0.15}{4\pi R^2}=4.77\;\left[\mathrm{W}\cdot\mathrm{m}^{-2}\right] \qquad (11.4.305)$$

The luminous power absorbed by the atom by its half-surface which faces the radiation is then:

$$P_K = I \cdot \frac{S_K}{2} = 4.77 \cdot 2\pi \frac{4\pi R_K^2}{2} = 4.77 \cdot 2\pi \left(0.5 \cdot 10^{-10}\right)^2 \cong 7.49 \cdot 10^{-20}\,[\text{W}] \qquad (11.4.306)$$

The time required for absorption is then:

$$t = \frac{E_l}{P_K} = \frac{2.25 \cdot 1.602 \cdot 10^{-19}}{7.49 \cdot 10^{-20}} \cong 4.8\,[s] \qquad (11.4.307)$$

Which is in contradiction with the experience where we observe that the phenomenon is almost instantaneous (time for light to travel to the metal).

2. If we reverse the poles, the electrons emitted by the metal are pushed back by the negative electrode, but if the reverse voltage is not to big the faster ones can still reach the negative electrode and a current will occur. At a negative potential, specific for each metal, named the equation "stop potential U_a", all the emitted electrons are pushed back and the current is zero. The maximum kinetic energy of these photoelectrons is then:

$$E_{c,\text{max}} = q_e U_q \qquad (11.4.308)$$

However, we see experimentally that this stopping potential is independent of the intensity of the radiation. In the Wave theory, the increase in intensity should increase the number of electrons extracted (regardless of their energy level) and their maximum kinetic energy. A greater intensity implies a greater amplitude of the electric field: $I \propto E^2$. Thus, a bigger electric field should eject the electrons at higher velocities from all layers of the electronic cloud as the intensity increases.

3. When we vary the frequency v of incident light and we measure U_a, we observe that the photoelectric effect does not occur if $\nu < \nu_0$ (ν_0 is named the "frequency threshold") and this whatever the intensity of the light. What is rather annoying... because in Wave theory, we must always be able to eject electrons whatever the frequency, we just have to increase the intensity.

Each problem can be solved by adopting the following point of view:

1. In the Wave theory approach, the source is seen as propagating like a spherical wavefront whose surface density of energy decreases as a $1/r^2$ (see section Electrodynamics page 4160). In order to explain the experimental observation, we must see the experiment from a corpuscular point of view where the wavefront is a front of corpuscles whose surface density of photons decreases in $1/r^2$ but where the energy of each photon remains $h\nu$ (according to the Planck-Einstein relation).

2. If we think in terms of photons, when we increase the intensity, we increase the number of photons, but the energy per photon $h\nu$ remains unchanged. Thus, the energy $E_{c,\text{max}}$ that each photon can have does not change. Hence the stopping potential is independent of the field intensity.

3. If we think in terms of photons again, the electrons in the target are retained by the attraction forces, extracting an electron from the surface requires a minimal energy E_l

that depends on each material (E_l is also named "extraction work" denoted W_i which is of the order of some electronvolts). If the energy of the incident photon $E_i = h\nu$ is greater than E_l, an electron can be extracted, but if it is inferior, no electron can be extracted. The energy input $h\nu$ is equal to the kinetic output energy of the electron plus the energy required to extract it from the metal, therefore:

$$E_c + E_l = E_i = h\nu \qquad (11.4.309)$$

Thus, if the frequency of light is increased, the maximum kinetic energy of the electrons increases linearly. R.A. Millikan made rigorous experiments between 11913 (holocene calendar) and 11914 (holocene calendar), the results were matching perfectly with Albert Einstein's theory.

Caution!!!! The photoelectric effect can however be explained without photons. It is an historical accident that the photon concept should have acquired its strongest early support from Einstein's considerations on the photoelectric effect! Indeed, we can understand the photoeffect as being the result of a classical field falling on a quantized atomic electron (see page **??**). The introduction of the photon concept is neither logically implied by nor necessary for the explanation of the photoelectric effect (it's just more convenient in most graduate curriculum because of a lack of time!).

The light spreads from place to place as if it were a wave. But light interacts with matter in absorption and emission processes as if it were a particle stream. We already know that this is the "wave-particle duality" (see section Wave Quantum Physics page 4688). Thus, as that latter can find in the mass particles as suggested by the de Broglie hypothesis that we have seen in the section of Wave Quantum Physics, is finally verified also for the light.

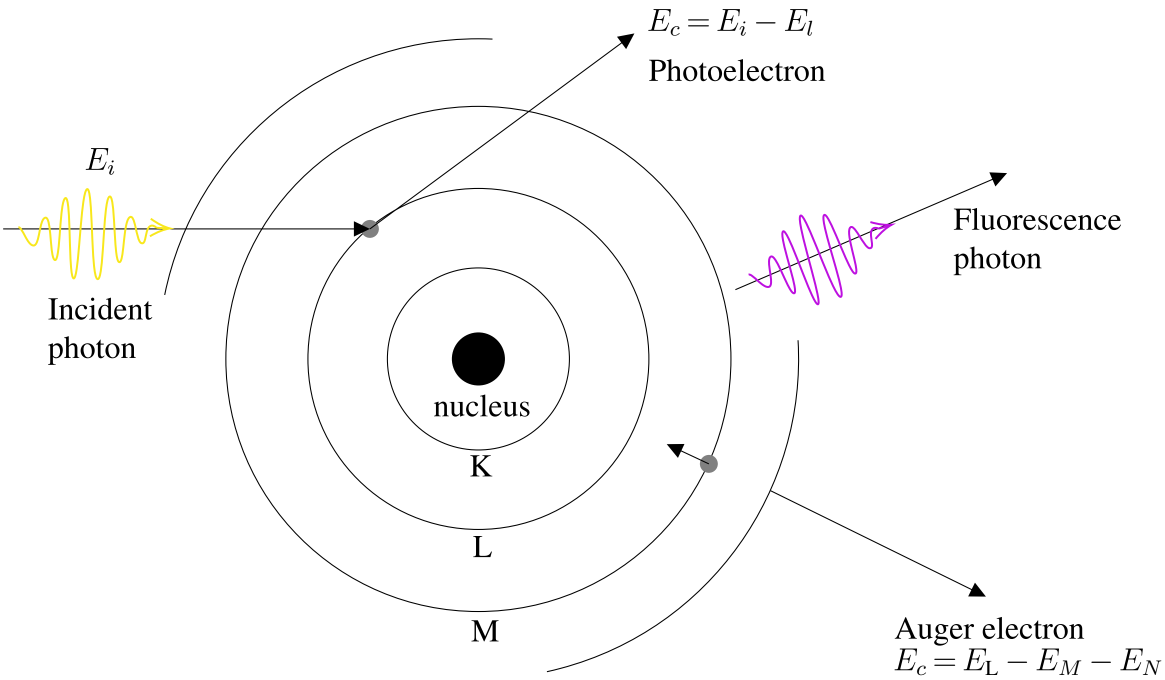

Figure 11.120: **Principle of the photoelectric effect on the Bohr model of the atom**

A photon of incident energy E_i which interacts with an electron of a target atom can eject this electron from its orbit by communicating to it a kinetic energy equation:

$$E_c = E_i - E_l \tag{11.4.310}$$

where E_l is the binding energy of the electron ejected from its orbit (this relation is given in the form $T = E - W_i$ in the figure above).

If the energy of the incident photon is lower than the binding energy of the electron of layer K (see section Corpuscular Quantum Physics page 4616), the photoelectric effect is done with an electron of the layer L, etc.

In the case where the radiation is absorbed, the atom is said to be "excited", because its energy state is not the minimum state. There follows a "relaxation" (or "de-excitation"): an electron of a higher layer fills the quantum space left vacant by the ejected electron.

If the transition energy is moderate (i.e., if the incident radiation has a moderate energy), relaxation causes the emission of a low-energy (visible or ultra-violet) photon, this is the phenomenon of fluorescence.

11.4.3.5 Rutherford scattering

Let us now consider the diffusion that a charged particle undergoes when it is subjected to an electrostatic repulsive force inversely proportional to the square of the distance between the moving particle and a fixed point or center of force. This problem is particularly interesting because of its application to atomic and nuclear physics. For example, when a proton, accelerated by a machine such as a cyclotron, passes near a core of the target's material, it is deflected by a force of this type from electrostatic repulsion of the nucleus. This study is referred to as the "Rutherford scattering" or "Coulomb scattering" and is mainly based on the following figure:

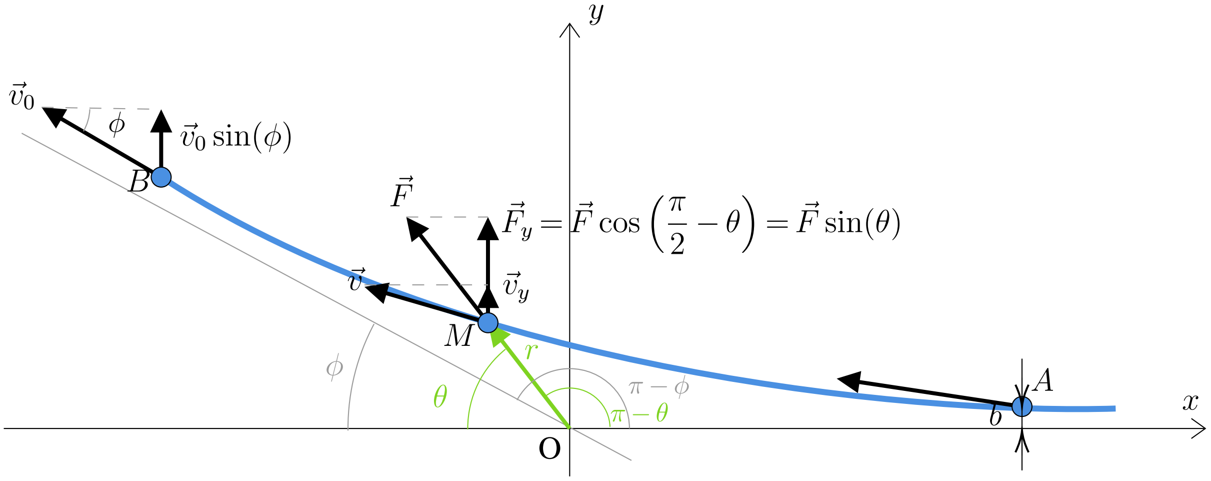

Figure 11.121: **Rutherford scattering**

Let O be a center of force and a particle thrown against O from a great distance with the velocity v_0 (see figure above) moving from right to left and entering the figure above at point A. We will choose The axis of X passing through O and parallel to v_0. The distance b, named the "impact parameter", is the distance between the x-axis of the abscissa and the point A. Assuming that the force between A and O is repulsive and central, the particle will follow the curved trajectory AMB. The shape of the curve depends on how the force varies with the distance. If the force is inversely proportional to the square of the distance, that is to say if:

$$F=\frac{K_e}{r^2}\qquad(11.4.311)$$

The trajectory is a hyperbola (indeed, the equation and solution are the same as Kepler problem, we just need to flip the sign of the constant K_e). Of course (see section Electrostatics page 3968):

$$K_e=\frac{1}{4\pi\varepsilon_0}ZqQ\qquad(11.4.312)$$

When the particle is in A its angular momentum is mv_0b. In any position such that M, its angular momentum (see section Classical Mechanics page 3244), is also given by $mr^2\dfrac{\mathrm{d}\theta}{\mathrm{d}t}$. Since the angular momentum must remain constant since the force is central:

$$mr^2\frac{\mathrm{d}\theta}{\mathrm{d}t}=mv_0b\qquad(11.4.313)$$

The equation of motion in the OY direction is obtained by injecting this relation into:

$$m\frac{\mathrm{d}v_y}{\mathrm{d}t}=F_y=F\sin(\theta)=\frac{K_e}{r^2}\sin\theta \tag{11.4.314}$$

so we can get rid of r^2 and write therefore:

$$m\frac{\mathrm{d}v_y}{\mathrm{d}t}=\frac{K_e}{v_0 b}\sin(\theta)\frac{\mathrm{d}\theta}{\mathrm{d}t} \tag{11.4.315}$$

To find the deviation of the particle, we must integrate this equation from one end of the trajectory to the other. In A the value of v_y is zero because the initial motion is parallel to the X axis and we also have $\theta=0$. In B we have $v_y=v_0\sin(\phi)$ and $\theta=\phi$ or $\pi-\theta=\pi-\phi$. We notice that in B the speed is again v_0 because, by symmetry, the speed lost when the particle approaches O must be regained when it moves away from it. Therefore:

$$\int\limits_0^{v_0\sin(\phi)}\mathrm{d}v_y=\frac{k}{mv_0b}\int\limits_0^{\pi-\phi}\sin(\theta)\mathrm{d}\theta \tag{11.4.316}$$

Which give:

$$v_0\sin(\phi)=-\frac{K_e}{mv_0b}\left(\cos(\pi-\phi)-1\right) \tag{11.4.317}$$

thus by using the common trigonometric relations:

$$v_0\sin\phi=\frac{K_e}{mv_0b}\left(1+\cos(\phi)\right) \tag{11.4.318}$$

and after rearrangement:

$$\frac{(1+\cos(\phi))}{\sin\phi}=\frac{mv_0^2b}{K_e} \tag{11.4.319}$$

Let us recall that (see section Trigonometry page 2519) that:

$$\tan(\alpha)=\frac{\sin(2\alpha)}{1+\cos(2\alpha)}=\frac{1}{\cot(\alpha)} \tag{11.4.320}$$

What then gives us:

$$\cot\left(\frac{1}{2}\phi\right)=\frac{mv_0^2b}{K_e} \tag{11.4.321}$$

Either more explicitly:

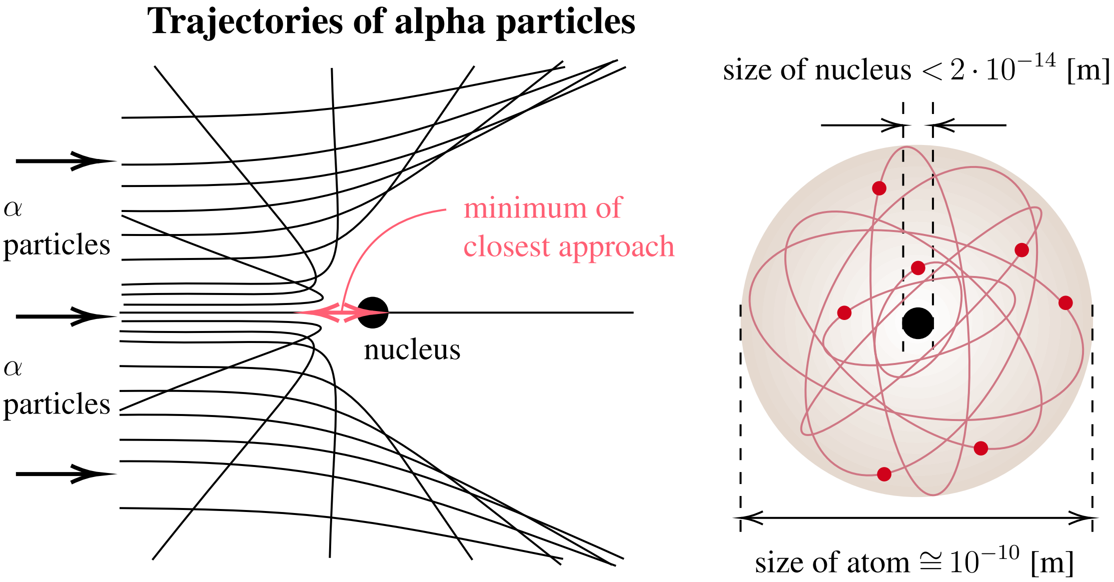
$$\cot\left(\frac{\phi}{2}\right)=\frac{4\pi\varepsilon_0mv_0^2b}{ZQq} \tag{11.4.322}$$

This relation gives the angle of deviation ϕ as a function of the impact parameter b:

$$b=\frac{1}{4\pi\varepsilon_0}\frac{ZQq}{mv_0^2}\cot\left(\frac{\phi}{2}\right) \tag{11.4.323}$$

Of course, in undergraduate cases, $Q=q$ is often put, which simplifies the previous relation slightly, but we then loses in generalization.

This equation is applied to the analysis of the deviation of an electrically charged particle by a nucleus. Let us notice that this result is only valid for a force inversely proportional to the square of the distance. If the force depends on the distance according to another law, the deflection angle satisfies another equation. The deviation experiments are therefore also very useful when we want to determine the law of force involved in the interactions between particles!



Trajectories of alpha particles
α particles
α particles
minimum of closest approach
nucleus
size of nucleus $< 2\cdot 10^{-14}$ [m]
size of atom $\cong 10^{-10}$ [m]

Figure 11.122: **Representation of the Rutherford diffusion of alpha nucleus**

In nuclear physics laboratories, diffusion experiments are carried out by accelerating electrons, protons or other particles by means of a cyclotron, a Van de Graaf accelerator or some other similar device, and by observing the angular distribution of the deflected particles.

It is clear that an incident particle in a surface defined by a radius between b and $b+\mathrm{d}b$ will be respectively included in the solid diffusion angle:

$$\mathrm{d}\sigma = 2\pi b\mathrm{d}b \qquad (11.4.324)$$

with (see section Trigonometry page 2549):

$$\mathrm{d}\Omega = 2\pi\sin(\phi)\mathrm{d}\phi \qquad (11.4.325)$$

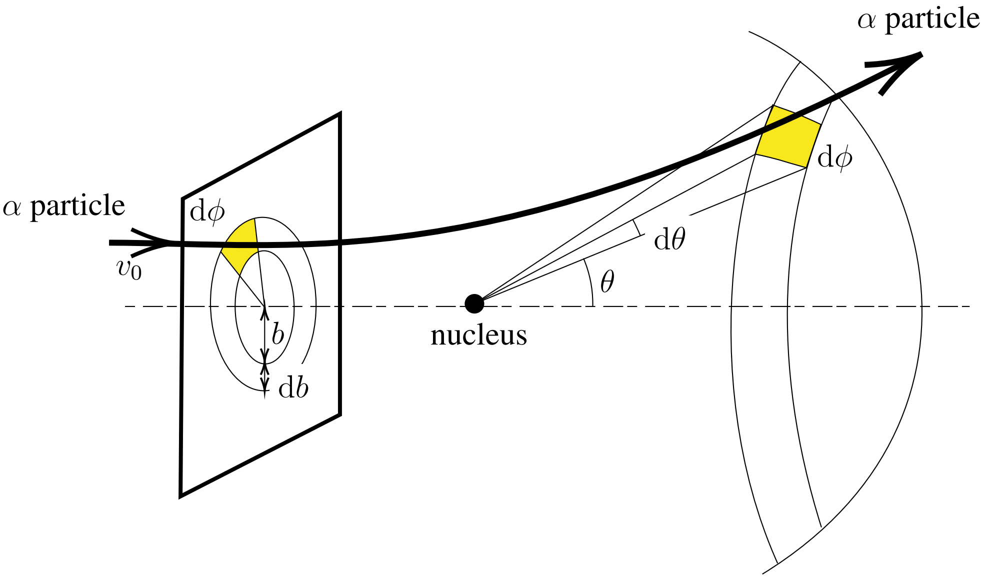


Figure 11.123: **Representation of the solid diffusion angle**

The "cross-section" or "differential cross-section" being defined in Nuclear Physics and in Particle Physics by:

$$\boxed{\frac{\mathrm{d}\sigma}{\mathrm{d}\Omega}=\frac{2\pi b\mathrm{d}b}{2\pi\sin(\phi)\mathrm{d}\phi}} \tag{11.4.326}$$

Starting from (relation proved just earlier above):

$$b=\frac{1}{4\pi\varepsilon_0}\frac{qQ}{mv_0^2}\cot\left(\frac{\phi}{2}\right) \tag{11.4.327}$$

and using the following usual derivative proved in the section of Differential and Integral Calculus (see page 1475):

$$\cot'(x)=-\frac{1}{\sin^2(x)} \tag{11.4.328}$$

we have:

$$\frac{\mathrm{d}b}{\mathrm{d}\phi}=\frac{1}{4\pi\varepsilon_0}\frac{qQ}{mv_0^2}\frac{\mathrm{d}}{\mathrm{d}\phi}\cot\left(\frac{\phi}{2}\right)=-\frac{1}{4\pi\varepsilon_0}\frac{qQ}{m\nu_0^2}\frac{1}{2\sin^2\left(\dfrac{\phi}{2}\right)} \tag{11.4.329}$$

Hence:

$$\mathrm{d}b=-\frac{1}{4\pi\varepsilon_0}\frac{qQ}{mv_0^2}\frac{1}{2\sin^2\left(\dfrac{\phi}{2}\right)}\mathrm{d}\phi \tag{11.4.330}$$

Therefore:

$$b\mathrm{d}b=-\left(\frac{1}{4\pi\varepsilon_0}\right)^2\left(\frac{qQ}{mv_0^2}\right)^2\frac{\cot\left(\dfrac{\phi}{2}\right)}{2\sin^2\left(\dfrac{\phi}{2}\right)}\mathrm{d}\phi=-\left(\frac{1}{4\pi\varepsilon_0}\right)^2\left(\frac{qQ}{mv_0^2}\right)^2\frac{\cos\left(\dfrac{\phi}{2}\right)}{2\sin^3\left(\dfrac{\phi}{2}\right)}\mathrm{d}\phi \tag{11.4.331}$$

Thus:

$$\begin{aligned}\frac{b\mathrm{d}b}{\sin(\phi)\mathrm{d}\phi}&=-\left(\frac{1}{4\pi\varepsilon_0}\right)^2\left(\frac{q\mathrm{Q}}{mv_0^2}\right)^2\frac{1}{2\sin^3\left(\dfrac{\phi}{2}\right)}\frac{\cos\left(\dfrac{\phi}{2}\right)}{\sin(\phi)}\\&=-\left(\frac{1}{4\pi\varepsilon_0}\right)^2\left(\frac{q\mathrm{Q}}{mv_0^2}\right)^2\frac{1}{2\sin^3\left(\dfrac{\phi}{2}\right)}\frac{\cos\left(\dfrac{\phi}{2}\right)}{2\sin\left(\dfrac{\phi}{2}\right)\cos\left(\dfrac{\phi}{2}\right)}\\&=-\left(\frac{1}{4\pi\varepsilon_0}\right)^2\left(\frac{q\mathrm{Q}}{mv_0^2}\right)^2\frac{1}{4\sin^4\left(\dfrac{\phi}{2}\right)}\end{aligned}\tag{11.4.332}$$

We have then, remembering that the member on the left is nothing but the effective section:

$$\begin{aligned}\frac{\mathrm{d}\sigma}{\mathrm{d}\Omega}&=-\frac{(q\mathrm{Q})^2}{(4\pi\varepsilon_0)^2m^2v_0^4}\frac{1}{4\sin^4\left(\dfrac{\phi}{2}\right)}=-\frac{(q\mathrm{Q})^2}{(4\pi\varepsilon_0)^2 4\dfrac{1}{4}m^2v_0^4}\frac{1}{4\sin^4\left(\dfrac{\phi}{2}\right)}\\&=-\frac{(q\mathrm{Q})^2}{16(4\pi\varepsilon_0)^2E_c^2}\frac{1}{\sin^4\left(\dfrac{\phi}{2}\right)}\end{aligned}\tag{11.4.333}$$

and it is customary to take the absolute value to define the "effective (differential) section of Rutherford (or Coulomb)":

$$\boxed{\frac{\mathrm{d}\sigma}{\mathrm{d}\Omega}=\frac{(q\mathrm{Q})^2}{16(4\pi\varepsilon_0)^2E_c^2}\frac{1}{\sin^4\left(\dfrac{\phi}{2}\right)}}\tag{11.4.334}$$

Interestingly, a fully quantum mechanical calculation (albeit non-relativistic) would yield exactly the same answer!

We notice several interesting things:

1. For an angle of incidence equal to zero, the effective cross-section diverges (because of the sinus in the denominator)
2. The effective section decreases according to the square of the kinetic energy of the incident particle
3. The expression is valid whatever the charges involved (positive or negative)

Thanks to the Rutherford / Coulomb scattering, Rutherford was able to determine an approximation of the size of the nucleus of the atom (bombardment of a gold leaf[38] using alpha nuclei) as we did notice it at the beginning of the section of Corpuscular Quantum Physics. The reasoning applied is as follows to determine a lower bound of the radius of the nucleus:

---

[38] His best estimate came not from his famous gold foil but form lighter aluminium foil, a much less exotic material.

The total energy of a rotating system is the kinetic energy of translation summed with the kinetic energy of rotation, summed to the potential energy. Which gives us:

$$E=\frac{1}{2}m\dot{r}^2+\frac{1}{2}m\omega^2r^2+U(r)=\frac{1}{2}m\dot{r}^2+\frac{1}{2}mr^2\dot{\theta}^2+U(r) \qquad (11.4.335)$$

By denoting by L the angular momentum given by $L=mr^2\dot{\theta}$ (see section Classical Mechanics page 3244) we have:

$$E=\frac{1}{2}m\dot{r}^2+\frac{L^2}{2mr^2}+U(r) \qquad (11.4.336)$$

hence:

$$\dot{r}=\frac{\mathrm{d}r}{\mathrm{d}t}=\sqrt{\frac{2}{m}\left(E-\frac{L^2}{2mr^2}-U(r)\right)}=\frac{\mathrm{d}r}{\mathrm{d}\theta}\frac{\mathrm{d}\theta}{\mathrm{d}t} \qquad (11.4.337)$$

It therefore follows:

$$\mathrm{d}\theta=\frac{L\mathrm{d}r}{r^2\sqrt{2m\left(E-\frac{L^2}{2mr^2}-U(r)\right)}} \qquad (11.4.338)$$

From this it follows that the angle associated with two radial distances r_1, r_2 is given by:

$$\Delta\theta=\int_{r_1}^{r_2}\frac{L\mathrm{d}r}{r^2\sqrt{2m\left(E-\frac{L^2}{2mr^2}-U(r)\right)}} \qquad (11.4.339)$$

The figure below shows a process of collision by a central potential $U(r)$. The incident particle has an initial speed:

$$v=\sqrt{\frac{2E_c}{m}} \qquad (11.4.340)$$

in $t=-\infty$ with $z(t=-\infty)$ and $y(t=+\infty)$ by symmetry again.

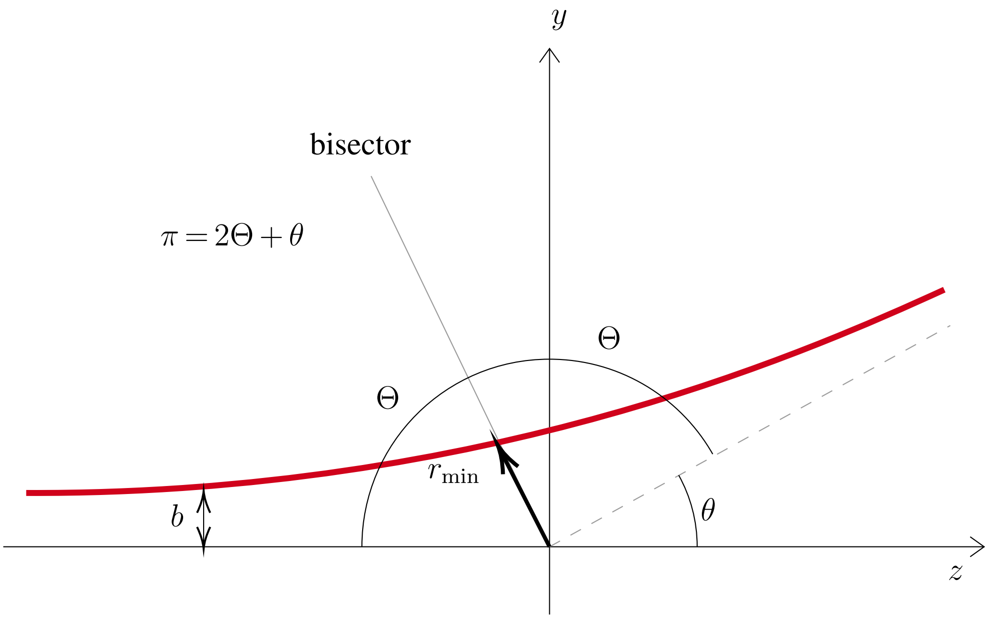

Figure 11.124: Schematic approach for determining the radius of the target

The angle Θ is the angle of deflection when the incident particle approaches the diffuser at the minimum distance r_{min}.

Let us return to our equations where the angular momentum is linked to the impact parameter by the relation $L=mvb$ or written differently:

$$L=b\sqrt{2mE_c} \tag{11.4.341}$$

We can therefore write after simplifications:

$$\begin{aligned}\Delta\theta=\int\limits_{r_1}^{r_2}\frac{L\mathrm{d}r}{r^2\sqrt{2m\left(E-\dfrac{L^2}{2mr^2}-U(r)\right)}}&\Rightarrow\Theta=\int\limits_{r_{\text{min}}}^{+\infty}\frac{b\sqrt{2mE_c}\mathrm{d}r}{r^2\sqrt{2m\left(E-\dfrac{L^2}{2mr^2}-U(r)\right)}}\\
=\int\limits_{r_{\text{min}}}^{+\infty}\frac{b\mathrm{d}r}{r^2\dfrac{1}{\sqrt{2mE_c}}\sqrt{2m\left(E-\dfrac{L^2}{2mr^2}-U(r)\right)}}&=\int\limits_{r_{\text{min}}}^{+\infty}\frac{b\mathrm{d}r}{r^2\sqrt{\dfrac{\cancel{2m}}{\cancel{2m}E_c}\left(E-\dfrac{b^2E_c\cancel{2m}}{\cancel{2m}r^2}-U(r)\right)}}\\
=\int\limits_{r_{\text{min}}}^{+\infty}\frac{b\mathrm{d}r}{r^2\sqrt{\dfrac{E}{E_c}-\dfrac{b^2}{r^2}-\dfrac{U(r)}{E_c}}}=\int\limits_{r_{\text{min}}}^{+\infty}&\frac{b\mathrm{d}r}{r^2\sqrt{1-\dfrac{b^2}{r^2}-\dfrac{U(r)}{E_c}}}=\int\limits_{r_{\text{min}}}^{+\infty}\frac{b\mathrm{d}r}{\sqrt{r^4-r^2b^2-\dfrac{r^4U(r)}{E_c}}}\\
=\int\limits_{r_{\text{min}}}^{+\infty}\frac{b\mathrm{d}r}{\sqrt{r^2\left(r^2-r\dfrac{A}{E_c}-b^2\right)}}&\end{aligned} \tag{11.4.342}$$

Where we put $E\cong E_c$ (the rotation energy and the potential energy are considered negligible with respect to the kinetic energy) and:

$$U(r)=\frac{1}{4\pi\varepsilon_0}\frac{\mathrm{Z}_1\mathrm{Z}_2q_e^2}{r}=\frac{A}{r} \tag{11.4.343}$$

The minimum approach distance is thus determined by the largest zero of the denominator:

$$r^2-\frac{A}{E_c}r-b^2=0 \tag{11.4.344}$$

That is to say (trivial):

$$r_{\text{min}}=\frac{\dfrac{A}{E_c}+\sqrt{\left(\dfrac{A}{E_c}\right)^2+4b^2}}{2}=\frac{A}{2E_c}+\sqrt{\left(\frac{A}{2E_c}\right)^2+b^2} \tag{11.4.345}$$

So we have:

$$\boxed{r_{\text{min}}=\frac{A}{2E_c}\left[1+\sqrt{1+\left(\frac{E_cb}{A}\right)^2}\right],A=\frac{\mathrm{Z}_1\mathrm{Z}_2q_e^2}{4\pi\varepsilon_0},E_c=\frac{1}{2}mv_0^2} \tag{11.4.346}$$

As we see in this last relation, the incident particle will undergo a frontal collision when $b=0$. Therefore, the value of the maximum approach is:

$$r_{\text{min}}=\dfrac{A}{E_c}=\dfrac{Z_1 Z_2 q_e^2}{4\pi\varepsilon_0 E_c} \tag{11.4.347}$$

Rutherford's experiment made it possible to estimate the size of the atomic nucleus. Indeed, the particles that have bounced back on the nucleus with a diffusion angle of 180° (we are then talking of "backscattering") are those that have approached nearest to the latter. Since we have:

$$\dfrac{1}{2}mv_0^2=\dfrac{1}{4\pi\varepsilon_0}\dfrac{Z_1 Z_2 q_e^2}{r_{\text{min}}} \tag{11.4.348}$$

with an initial kinetic energy of 7.7 [MeV], Rutherford found for the radius of the gold atom ($Z=79$) with alpha particles ($Z=2$) a value of:

$$a_0:=r_{\text{min}}=3\cdot 10^{-14}\;[\text{m}] \tag{11.4.349}$$

Thus, the nucleus is not punctual but of the order of ten tens of femtometres!

Thomson and Rayleigh scattering are elastic: only the direction
of the photon changes, not its energy. Plus they are only important at low
energies (where the photelectric effect dominates).
Rutherford scattering is also an elastic scattering in a Coulomb potential.

Figure 11.125: Summary of most well known type of scattering

11.4.3.6 X-rays and Gamma rays

The fundamental difference of this type of radiation, with respect to the α, β^-, β^+ is that it does not carry an electric charge and therefore does not have a coulombic interaction with the electronic cloud of the medium traversed. Consequently, the photon follows a straight path without loss of energy until it encounters a particle on its path (electron, nucleus) where it will undergo an interaction that profoundly alters its state.

"Gamma radiation" is a high-energy electromagnetic radiation produced by a nuclear phenomenon, while "X-rays radiation" are high-energy electromagnetic radiation produced during atomic or molecular phenomena. The photon is the elementary particle that is associated with these electromagnetic waves. The X and gamma photon are therefore of the same nature but of different origins, they therefore have identical properties that depend on their energy.

Let us recall that:

$$E=h\nu=\frac{hc}{\lambda} \qquad p=\frac{h\nu}{c}=\frac{h}{\lambda} \tag{11.4.350}$$

By crossing mater a photon can interact with:

- One of the electrons of the atom cloud
- The nucleus of the atom
- The electric field of charged atomic particles
- The meson field of the nucleons (strong interaction)

The result of the interaction can be schematized as follows:

- The photon is deflected by conserving its energy, then there is "total diffusion" of the energy and the process is say to be "coherent" (elastic).
- The photon is deflected and its energy decreased, then there is "partial diffusion" of energy, the other part is absorbed by matter, the process is then say to be "incoherent" (inelastic).
- The photon disappears, there is "total absorption" of its energy by matter.

We can prove that the macroscopic characteristics of these interactions in the framework of a thin and collimated beam lead to an exponential law of attenuation of photonic radiation in matter. This means that for photons there is no finite path (!) as for charged particles; It can never be assured that at a given distance all the photons of a beam have interacted.

The number of particles interacting with the material obviously depends on the intensity I and the type of material traversed (characterized by the "linear attenuation coefficient μ") and its thickness x.

We have:

$$\mathrm{d}I=-\mu I\mathrm{d}x \tag{11.4.351}$$

the "$-$" sign being there to show a decrease. We easily solve this differential equation (it is simply the Beer-Lambert law that we have already studied in the section of Geometric Optics):

$$I=I_0e^{-\mu x} \tag{11.4.352}$$

with I_0 being the initial intensity or "flow rate of fluence" and μ being the coefficient of linear attenuation in [cm^{-1}] which takes into account all the possible attenuation effects.

Remark

Often in the tables, we find the coefficient of attenuation mass μ/ρ expressed in [cm^2·g^{-1}]. We have then:

$$I=I_0e^{-\frac{\mu}{\rho}\rho\mathrm{d}x} \tag{11.4.353}$$

In the case of an absorbent containing several homogeneously distributed chemical elements, the attenuation coefficient is equal to:

$$\mu_T=\sum_i w_i\mu_i \quad \text{or} \quad \left(\frac{\mu}{\rho}\right)_T=\sum_i w_i\left(\frac{\mu}{\rho_i}\right) \tag{11.4.354}$$

where μ_T is the absorption coefficient of the absorbent, μ_i the absorption coefficient of the element i, ρ_T the density of the absorbent, ρ_i the density of the element i, w_i being the mass fraction of the element i in the absorbent.

Let us now take a microscopic approach:

Let a beam of I [particles· cm^{-2}·s^{-1}] striking perpendicularly the surface of a material of thickness $\mathrm{d}x$ and of atomic density N [atoms·cm^{-3}]. If we consider the particles striking the surface S, the latter can theoretically encounter $N\cdot S\cdot\mathrm{d}x$ target atoms in this layer. The number of particles interacting will be proportional to the intensity times this number and we will have:

$$\mathrm{d}I\cdot S=-\sigma\cdot I\cdot N\cdot S\cdot\mathrm{d}x \tag{11.4.355}$$

where σ is the constant of proportionality, named "microscopic cross section". Its units are often expressed in [barn] (1 [barn]=10^{-24} [cm^2]).

Remarks

R1. The atomic density N is equal to $\rho N_\mathrm{A}\cdot M_m^{-1}$ where $\rho$is the density in [g· cm^{-3}] of the target, N_A the Avogadro constant ($6.022\cdot10^{23}$ [atoms·mole^{-1}]) and M_m is the molar mass of the target expressed in [g· mole^{-1}].

R2. If we admit that the diffusion centers are the electrons and not the target atoms, then we have to replace N by $N_e=N\cdot Z$.

From where we get:

$$I=I_0e^{-NZ\sigma x}=I_0e^{-N_e\sigma x}=I_0e^{-\frac{ZN_\mathrm{A}\rho\sigma}{M_m}x} \tag{11.4.356}$$

By identifying the macro and microscopic aspect, we see that μ plays the same role as $ZN_\text{A}\rho\sigma/M_m$ and that we find that the effective section can be written as:

$$\sigma = \frac{\mu}{\rho}\frac{M_m}{ZN_\text{A}} \tag{11.4.357}$$

and in the hypothesis that the electron constitutes a "sphere of action" having a frontal surface πr_e^2, where $r_e$is the radius of the sphere of action then:

$$\sigma = \pi r_e^2 = \frac{\mu}{\rho}\frac{M_m}{ZN_\text{A}} \tag{11.4.358}$$

and we have:

$$r_e = \sqrt{\frac{\mu}{\rho}\frac{M}{ZN_\text{A}\pi}} \tag{11.4.359}$$

By definition, we name the "Half-Attenuation Elbow (HAE)" the thickness of the material that divides the fluence rate I_0 by a factor of two. Therefore:

$$\frac{I_0}{2} = I_0 e^{-\mu x} \Rightarrow \frac{1}{2} = e^{-\mu x} \Rightarrow \ln\left(\frac{1}{2}\right) = -\mu x \Rightarrow x = -\frac{\ln\left(\frac{1}{2}\right)}{\mu} = -\frac{\ln(2)}{\mu} = \text{HAE} \tag{11.4.360}$$

In radio-protection, we sometimes use the notion of attenuation layer to the tenth TVL (Tenth Value Layer) given by:

$$\text{TVL} = \frac{\ln(10)}{\mu} \tag{11.4.361}$$

We sometimes also use the "relaxation length", which represents the thickness from which the intensity of a monoenergetic beam is decreased by a factor e, and which is therefore given by:

$$\lambda = \frac{1}{\mu} \tag{11.4.362}$$

This value is much more useful than the others, because it is also the average distance at which the first photon collision takes place.

Almost everyone going to the dentists or who broke some bones know how useful are X-rays the make diagnostics. However, far fewer people know how mathematics and X-rays associated together are useful to generate 3D detailed internal images of the body thanks to "Computed Tomography scan" (usually abbreviated "CT Scan"; formerly named "Computed Axial Tomography scan" or "CAT scan").

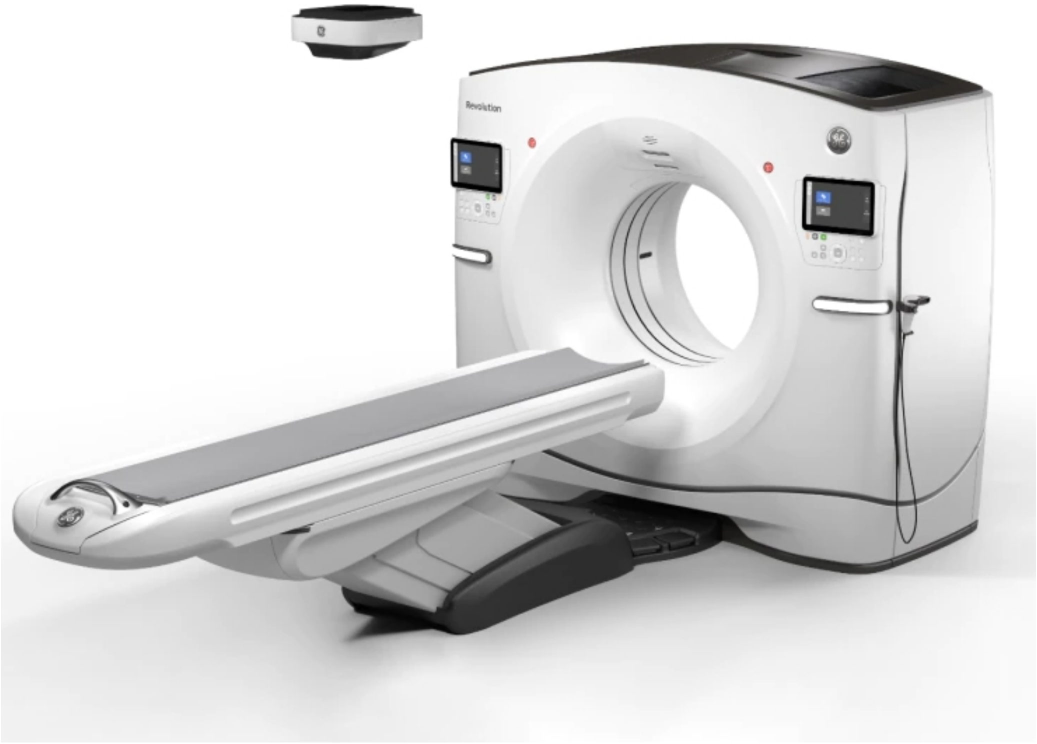

Figure 11.126: **General Electrics CT Scan Revolution model**

"Single-Photon Emission Computed Tomography" (SPECT) is a nuclear medicine tomographic imaging technique using gamma rays. It is very similar to conventional nuclear medicine planar imaging using a gamma camera (that is, scintigraphy) and is also able to provide 3D detailed internal images of the body. The technique needs delivery of a gamma-emitting radioisotope (a radionuclide) into the patient, normally through injection into the bloodstream. On occasion, the radioisotope is a simple soluble dissolved ion, such as an isotope of gallium.

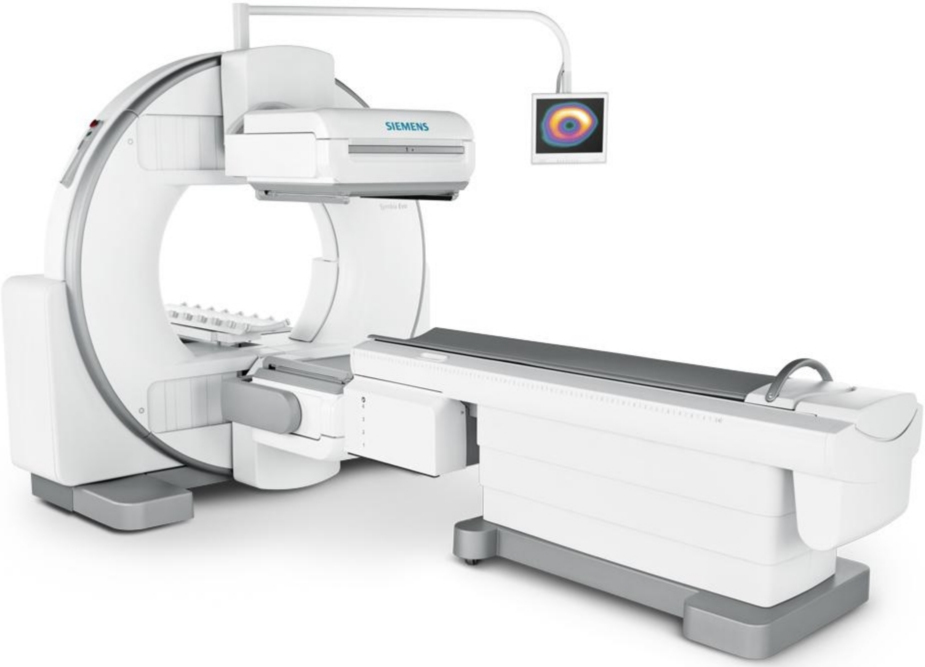

Figure 11.127: **Siemens SPECT scan Symbia model**

Remark

The Gamma irradiation is anecdotally used in the conservation of the heritage of organic objects. Indeed, during the discovery of archaeologists of ancient works or vestiges, the latter are attacked by micro-organisms that will destroy these objects over time. The gamma radiation will allow, without destroying the objects, to kill by gamma irradiation all these micro-organisms. The best known example is the irradiation of the Tutankhamun's mummy during 10 hours in the CEA laboratories.

An illustration of the most well known effect of gammas rays:

Figure 11.130: Pair creation with gamma ray naive Bohr model perspective (author: Poul Riis)

The known microscopic causes of the attenuation of a photon beam (neutral from the Coulombian point of view) which deserve our attention in the energy domain of gamma or X-ray photons are:

- Coherent Thomson scattering

- Coherent Rayleigh scattering
- Coherent Delbrück scattering
- Raman scattering (inelastic equivalent of Rayleigh scattering)
- Coherent Compton scattering (already partially seen earlier above)
- Photoelectric absorption (already partially seen earlier above)
- Photonuclear reaction
- Creation of electron-positron pairs (already partially seen earlier above)

Although we can now discuss these effects, it is impossible for us in the present state of this textbook to introduce the mathematical formalism used to determine the effective cross-section of each of these scattering.

11.4.3.6.1 Electron-Positron pair production

The concept of the wave-particle duality which means all matter has both "particle-like" and "wave-like" nature has been the inception of the quantum physics. Especially, for the "particle-like" nature, there are some examples that can be an empirical proof: first two processes as proves are the photoelectric effect and the Compton effect. Those two effects are well-known processes of photon absorption or scattering that photon loses its energy by interacting with other matter as a "particle-like" things.

The final one for proving "particle-like" nature of all matter is "pair production" or especially the special case of "electron-positron pair production". It was first observed by the physicist, Patrick Blackett, who was the winner of the 11948 (holocene calendar) Novel Prize in physics. While both the two processes mentioned above - the photoelectric effect and the Compton effect - usually occur in low energy and middle energy condition, pair production interaction is known to occur when photon has high enough energy before its collision.

The pair production is a crucial example that photon energy (gamma ray) can convert into kinetic energy as well as rest mass energy:

$$\gamma \rightarrow e^- + e^+ \tag{11.4.363}$$

Schematic diagram about the process of pair production is shown in the figure below. The high-energy photon that has energy $h\nu$ loses its entire energy when it collides with nucleus. Then, it makes pair of electron and positron and gives kinetic energy to each particle.

Basically, these interactions are ruled by three kind of the law of conservation: total energy, momentum, and electric charge.

During the creation of pairs, the photon absorbed in the electric field of the nucleus can generate an electron-positron pair. For the interaction to take place, the energy of the photon must be greater than the $2m_0c^2$ (about 1.02 [MeV]) that is to say the energy at rest of the electron-positron pair.

This effect is important for high energies and high atomic numbers. The positron created is braked in matter just like an electron and, at the end of the course, it annihilates with an electron to give rise to two photons of 0.511 [MeV] ("annihilation photons") emitted almost at $180°$ (the whole linear momentum being transformed into energy explains the value of this angle, so the final linear momentum is zero).

The creation of a pair obviously costs at least the mass energy of the electron and the positron, or $2m_0c^2$. The energy balance is then divided into the kinetic energy of the two particles:

$$h\nu = 2m_0c^2 + E_c^{\beta+} + E_c^{\beta-} \tag{11.4.364}$$

The necessity of simultaneously satisfying the conditions of conservation of the mass energy and the linear momentum the other hand imposes on the materialization effect to take place in the vicinity of a material particle (nucleus most of time) which participates in the phenomenon. Indeed, in vacuum, the two conditions are contradictory! The linear momentum of each electron is:

$$p_{\beta^+,\beta^-} = mv \tag{11.4.365}$$

We have proved in the section of Special relativity that:

$$mc^2 = E_c + m_0c^2 = E_{\text{tot}} \tag{11.4.366}$$

And therefore:

$$p_{\beta^+,\beta^-} = mv = \frac{E_{\text{tot}}}{c^2}v = \frac{E_c + m_0c^2}{c^2}v \tag{11.4.367}$$

Therefore:

$$E_{\text{tot}} = p_{\beta^+,\beta^-}\left(\frac{c^2}{v}\right) \tag{11.4.368}$$

The original photon has:

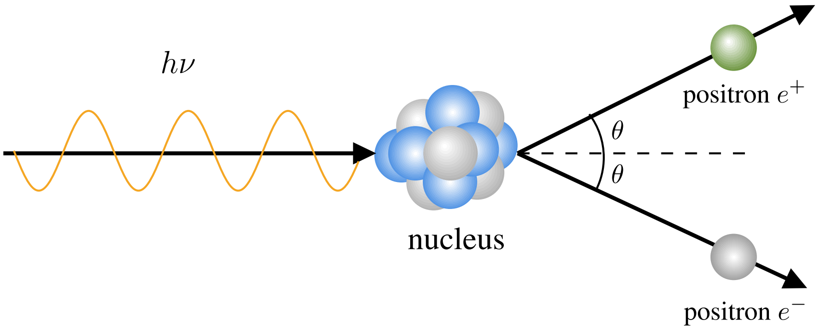
$$h\nu = 2E_{\text{tot}} \quad \text{and} \quad p_\gamma = \frac{h\nu}{c} \tag{11.4.369}$$

which we introduce into the energy conservation equation and with the help of the relation p_{β^+,β^-} we have:

$$h\nu = p_\gamma c = 2E_{\text{tot}} = 2p_{\beta^+,\beta^-}\left(\frac{c^2}{v}\right) \tag{11.4.370}$$

which shows that by the term $c^2/v > 1$ that the nucleus must take away a part of the linear momentum since:

$$p_{\beta^+,\beta^-} < p_{\beta^+,\beta^-}\left(\frac{c^2}{\nu}\right) \tag{11.4.371}$$



The presence of an electric field of a heavy atom such as lead or uranium is then essential in order to satisfy conservation of momentum and energy. In order to satisfy both conservation of momentum and energy, the atomic nucleus must receive some momentum.

Positron
A more energetic electron-positron pair
Scattered atomic electron

Figure 11.131: **Electron-Positron pair production in a bubble chamber**

Remark

Pair production is invoked to predict the existence of hypothetical Hawking radiation. According to quantum mechanics, particle pairs are constantly appearing and disappearing as a quantum foam. In a region of strong gravitational tidal forces, the two particles in a pair may sometimes be wrenched apart before they have a chance to mutually annihilate. When this happens in the region around a Black Hole, one particle may escape while its antiparticle partner is captured by the Black Hole.

11.4.3.7 Radiation dosimetry

In what follows, the radiation field is characterized in terms of energy and flux at a point of space. These physical datas than make possible to obtain the radiometric and dosimetric quantities of reference for external exposure, such as: fluence, kerma for the indirectly ionizing radiations and the dose. In addition, other quantities such as linear energy transfer (this parameter reflects the energy loss of charged particles per unit path length) and relative biological effectiveness are detailed; they relate to the effect of radiation on biological tissues and to the damage that can occur at the cellular level.

Initially, we will attempt to define the characteristic quantities of dosimetry and radiation fields (i.e. radiometric quantities). The fundamental radiometric and dosimetric quantities are essentially threefold: fluence Φ, absorbed dose $\mathcal{D}$ and Kerma K.

Definitions (#11.4.520):

D1. "Radiometric quantities" determine the strength of the radiation source(s). "Dosimetric quantities" are related to the energy transfer from radiation to matter.

Parameters describing a relation between those are named "interaction parameters". The intensity of a beam of particles in matter decreases according to the Beer-Lambert law (see section Optics page 4337):

$$I(x)=I_0e^{-\mu x} \tag{11.4.372}$$

where the linear attenuation coefficient is given by $\mu=(\mathrm{d}N/N)/\mathrm{d}x$. We define also the "mass absorption coefficient" by the simple ratio: μ/ρ.

D2. The deceleration of a heavy particle is described by the Bethe-Bloch formula proved earlier above (see page 5092):

$$L_\Delta=-\frac{\mathrm{d}E}{\mathrm{d}x}\propto\frac{e^4}{v^2} \tag{11.4.373}$$

and defines the "linear energy transfer".

$1,000$	6.805753
$1,500$	5.525981

Table 11.20: **Linear attenuation coefficient of γ rays in human body**

D3. The "fluention" or "fluence" is defined by $\Phi = \mathrm{d}N/\mathrm{d}S$. The *flux* is obviously given by $\phi = \mathrm{d}\Phi/\mathrm{d}t$. The energy loss is defined by $\Psi = \mathrm{d}W/\mathrm{d}S$, and the energy flux density $\psi = \mathrm{d}\Psi/\mathrm{d}t$.

D4. The "radiation dose" $\mathcal{X}$ is the amount of charge produced by the radiation per unit of mass, with unit $[\mathrm{C}\cdot\mathrm{kg}^{-1}]$ (Coulomb per kilo). An old unit is the "Röntgen":

$$1\,[\mathrm{Ro}] = 2.58\cdot 10^{-4}\,[\mathrm{C}\cdot\mathrm{kg}^{-1}] \qquad (11.4.374)$$

With the "energy-absorption coefficient" μ_E follows:

$$\mathcal{X} = \frac{\mathrm{d}Q}{\mathrm{d}m} = \frac{q + e\mu_E}{W\rho}\Psi \qquad (11.4.375)$$

where the underlying idea is that W is the energy required to disjoin an elementary charge.

D5. The "absorbed dose" $\mathcal{D}$ is defined by:

$$\mathcal{D} = \frac{\mathrm{d}E_{\text{abs}}}{\mathrm{d}m} \qquad (11.4.376)$$

with for unit the "Gray" simply defined as $[\mathrm{Gy}] = [\mathrm{J}\cdot\mathrm{kg}^{-1}]$.

Remark

An old unit is the rad: $1\,[\mathrm{rad}] = 0.01\,[\mathrm{Gy}]$.

D6. The "Kerma" K is the amount of kinetic energy of secondary produced particles which is produced per mass unit of the radiated object.

D7. The "equivalent dose" $\mathcal{H}$, measured in Sieverts $1\,[\text{Sv}]=1\,[\text{J}\cdot\text{kg}^{-1}]$, is a weighted average of the absorbed dose per type of radiation, where for each type radiation the effects on biological material is used for the weight factor. These weight factors are named the "quality factors".

Calculating equivalent dose from absorbed dose is given by:

$$\mathcal{H}_T=\sum_R w_R \mathcal{D}_{T,R} \tag{11.4.377}$$

where:

- $\mathcal{H}_T$ is the equivalent dose in sieverts (Sv) absorbed by tissue or organ T
- $\mathcal{D}_{T,R}$ is the absorbed dose in grays (Gy) in tissue T by radiation type R
- w_r is the radiation weighting factor defined by regulation

Thus for example, an absorbed dose of $1\,[\text{Gy}]$ by alpha particles will lead to an equivalent dose of $20\,[\text{Sv}]$, and an equivalent dose of radiation is estimated to have the same biological effect as an equal amount of absorbed dose of gamma rays, which is given a weighting factor of 1.

Radiation type	w_R
Röntgen, gamma radiation	1
β, electrons, mesons	1
Thermic neutrons	3 to 5
Fast neutrons	10 to 20
protons	10
α, fission products	20

Remark

A dose of 1 Sievert is commonly associated with approximately a 5.5% increase in the risk of fatal cancers. The normal daily radiation dose received by the average person living on Earth is 10 microsieverts. This value is approximately $250,000$ bigger for a planet like Mars....

D8. "Effective dose" $\mathcal{E}$ is calculated for the whole body. It is the addition of equivalent doses to all organs, each adjusted to account for the sensitivity of the organ to radiation. Effective dose is also expressed in Sieverts and given by:

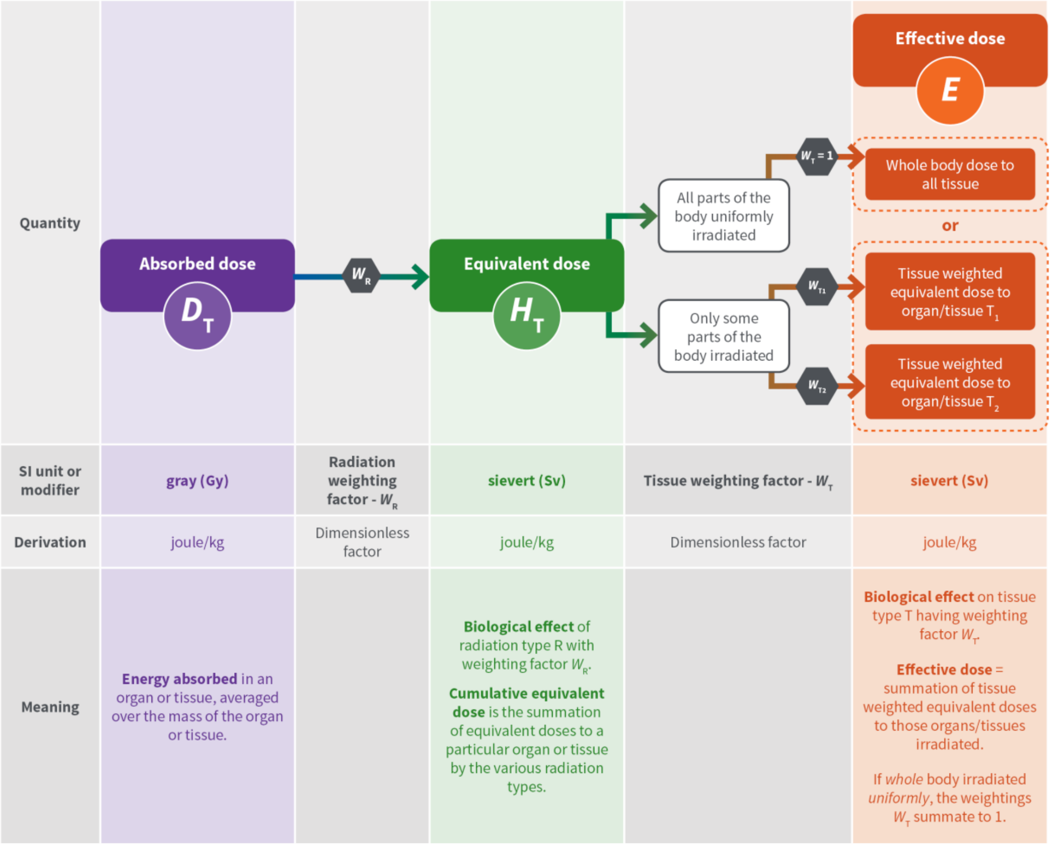
$$\mathcal{E}=\sum_T w_T\mathcal{H}_T=\sum_T w_T\left(\sum_R w_R\mathcal{D}_{T,R}\right)=\sum_T w_T\left(\sum_R w_R\frac{\mathrm{d}E_{\text{abs,T,R}}}{\mathrm{d}m}\right) \tag{11.4.378}$$

where w_T is a weighted factor for a given organ.

Typically for Homo Sapiens we have:

Organ	w_T
Gonads	0.20
Red bone marrow	0.12
Colon	0.12
Lungs	0.12
Stomach	0.12
Bladder	0.05
Breasts	0.05
Liver	0.05
Esophagus	0.05
Thyroid	0.05
Skin	0.01
Bone surface	0.01
Remainder	0.05
Total	1.00

The three previous definitions can be summarized with the following flowchart:



Quantity
Absorbed dose

joule/kg
Dimensionless factor
joule/kg
Meaning
Energy absorbed in an organ or tissue, averaged over the mass of the organ or tissue.
Biological effect of radiation type R with weighting factor W_R.
Cumulative equivalent dose is the summation of equivalent doses to a particular organ or tissue by the various radiation types.
Biological effect on tissue type T having weighting factor W_T.
Effective dose = summation of tissue weighted equivalent doses to those organs/tissues irradiated.
If whole body irradiated uniformly, the weightings W_T summate to 1.

Figure 11.132: **Summary of dosimetric quantities**

D9. The "equivalent period" T_{eq} is the time it takes for the number of atoms of an ingested or inhaled radionuclide to decrease by a factor of 2 in the human body. It is therefore linked to the half-life of the radionuclide $T_{1/2}$ but also to the biological half-life T_{bio} representative of the time necessary for the organism to release half of the quantity ingested or inhaled. It is defined by:

$$\frac{1}{T_{\text{eq}}}=\frac{1}{T_{1/2}}+\frac{1}{T_{\text{bio}}} \qquad (11.4.379)$$

Here is a table summarizing the different major units:

Type of unit	**S.I. unit**	**Conventional unit**
Radioactivity (A)	Becquerel [Bq]	Curie [Ci]
	1 [Bq] $=1$ disintegration per second 1[Ci] $=3.7\cdot 10^{10}$ disintegration per second	
Radiation dose (χ)	$[\text{C}\cdot\text{kg}^{-1}]$	Röntgen [Ro]
Absorbed dose ($\mathcal{D}$)	Gray [Gy]	[rad]
	1 [Gy] $=1\,[\text{J}\cdot\text{kg}^{-1}]=100$ [rad]	
Equivalent dose ($\mathcal{H}_T$)	Sievert [Sv]	[rem]
	1 [Sv] $=100$ [rem]	
Effective dose ($\mathcal{E}$)	Sievert [Sv]	[rem]
Linear energy transfer (L_Δ)	Newton [N]	$[\text{keV}\cdot\mu\text{m}^{-1}]$
	1 [N] $=1\,[\text{J}\cdot\text{m}^{-1}]$ $1\,[\text{keV}\cdot\mu\text{m}^{-1}]=1.6\cdot 10^{-13}$ [N]	

Table 11.21: **Summary of major radiation dosimetry units**

The natural radioactivity of the soil comes from its ^{40}K content as well as from the daughter products of uranium and thorium. Their concentration varies from region to region and is a few hundred $[\text{Bq}\cdot\text{kg}^{-1}]$ for the ^{40}K and a few tens of $[\text{Bq}\cdot\text{kg}^{-1}]$ for uranium and thorium daughter products. The effective dose from X-rays indoors is on average 1.5 times greater than in the open air. According to UNSCEAR[39] (11993 according to holocene calendar), the worldwide average effective dose, taking into account a residential occupancy rate of 0.8 is $0.35\,[\text{mSv}\cdot\text{year}^{-1}]$

The dose rate maps from terrestrial and space radiation of Switzerland are given in the figures below. The first concerns the radiation coming from space (cosmic rays), the second figure is the natural terrestrial radiation and the second the artificial terrestrial radiation coming mainly from the Chernobyl accident. The maximum ($90\,[\text{nSv}\cdot\text{h}^{-1}]$) is found in the south-eastern region of Switzerland because of the large amounts of rain which took place just after the accident. The latter caused the deposit of aerosols containing the radioactive products on the ground.

[39] United Nations Scientific Committee on the Effects of Atomic Radiation

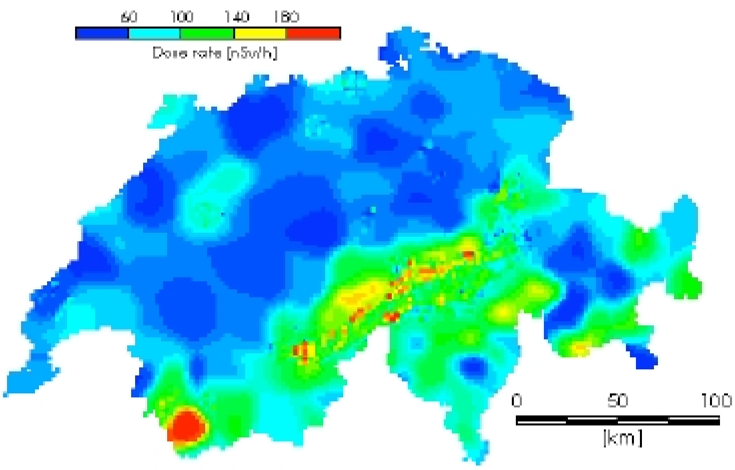

Figure 11.134: Natural terrestrial dose rate map (in nSv/h) of Switzerland. Min. value: 6; Max. value: 368; Average value: 68; Std. deviation: 35

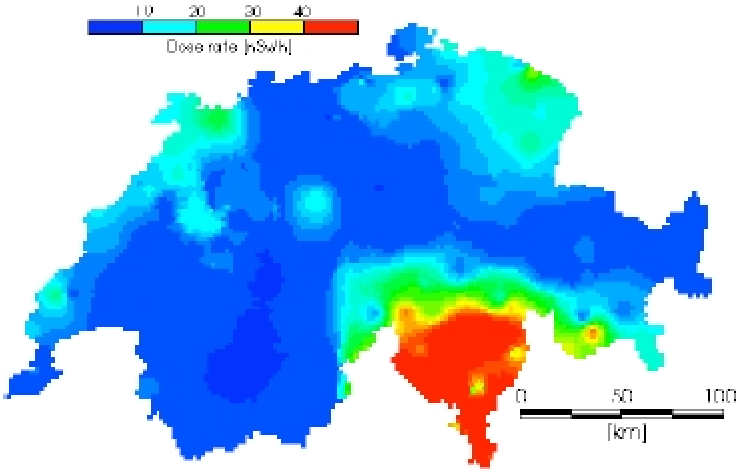

Figure 11.135: Artificial dose rate map (in nSv/h) of Switzerland. Min. value: 1; Max. value: 91; Average value: 11; Std. deviation: 14 (year 12000)

Drinking waters usually contain several natural radionuclides: tritium, radon, radium, uranium isotopes, etc (see [187]). Their concentrations vary widely since they depend on the nature of the aquifer, namely, the prevailing lithology and whether there is air in it or not. They are released from rocks and minerals which form the aquifer as happens with other cations and anions: processes of erosion and dissolution bring radioactive elements from rocks into the water. Some common natural radioelements are those from the uranium-238 chain, a natural radioactive series of many radionuclides, one descending from the other. The most relevant are uranium-238, uranium-234, radium-226 and radon-222. Relatively abundant in the Earth crust $^{238}\mathrm{U}$ and its descendant $^{234}\mathrm{U}$, are often the most abundant radionuclides in water[40] (see [114]). The occurrence of $^{222}\mathrm{Rn}$ may be important too; indeed, because of its moderate solubility in water, it rises mostly by emanation from inner soil layers rather than from the decay of the dissolved parent $^{226}\mathrm{Ra}$. In spite of the fact that the activity concentration of $^{222}\mathrm{Rn}$ in freshly drawn water may be more than two orders higher than that of other radionuclides, it readily diminishes as a result of both desorption and physical decay.

---

[40] In the USA $\sim 0.75 \cdot 10^{-6}$ [kg $\cdot$ L^{-1}] and in Europe $\sim 0.4 \cdot 10^{-6}$ [kg $\cdot$ L^{-1}] to some pic values of $\sim 100 \cdot 10^{-6}$ [kg $\cdot$ L^{-1}] in some Switzerland sources. Keeping in mind that the lethal dose (LD50) of Uranium is 114 [mg] per kilogram.

Another crucial radioactive family in drinking water is the thorium-232 series. Thorium is three to four times more abundant than uranium in the Earth's crust, but owing to its poor solubility it scarcely occurs in waters. Radium-228 belongs into this series and it may become a critical contaminant, as its radiotoxicity is relatively high.

Potassium-40 is also a widespread radionuclide in drinkable water. It is a beta-gamma emitter of primordial origin and goes along stable potassium in a fixed ratio (31.3 [Bq] per gram of stable potassium).

Tritium is a cosmogenic radionuclide; it is a hydrogen isotope formed in the high atmosphere. It occurs in rainfalls as tritiated water (HTO) at a concentration of roughly $5\,[\mathrm{Bq}\cdot\mathrm{L}^{-1}]$. It can be also produced by anthropogenic activities (research and nuclear facilities). It can reach the aquifers along their recharge process, but its concentration progressively decreases due to its relatively short decay time (13 years). Tritium has a low radiotoxicity. In fact its dose coefficient is three orders of magnitude lower than the coefficients of the natural chain radionuclides.

Many national and international institutions have published rules - mandatory or not - that carry the intent of managing the question of radioactivity in drinking water. A short review of the most significant ones is hereby presented:

- WHO (World Health Organization) guidelines for drinking water suggest performing an indirect evaluation of individual dose criterion (IDC) of $0.1\,[\mathrm{mSv}\cdot\mathrm{year}^{-1}]$ by measuring gross alpha and beta radioactivity and checking compliance of radionuclide activity concentration to derived guidance levels .
- The table shows a summary of the European regulations:

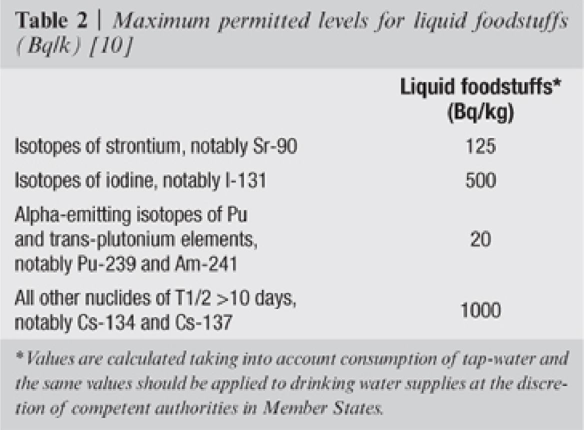

Table 2 | *Maximum permitted levels for liquid foodstuffs (Bq/k) [10]*

	Liquid foodstuffs* (Bq/kg)
Isotopes of strontium, notably Sr-90	125
Isotopes of iodine, notably I-131	500
Alpha-emitting isotopes of Pu and trans-plutonium elements, notably Pu-239 and Am-241	20
All other nuclides of T1/2 >10 days, notably Cs-134 and Cs-137	1000

**Values are calculated taking into account consumption of tap-water and the same values should be applied to drinking water supplies at the discretion of competent authorities in Member States.*

Figure 11.136: **European radioactivity permitted level for liquid foodstuffs**

- The table below shows a summary of the US Environmental Protection Agency (USEPA):

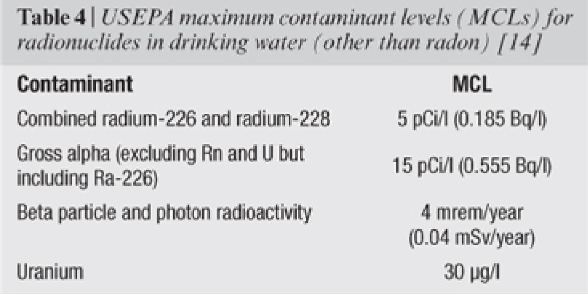

Table 4 | *USEPA maximum contaminant levels (MCLs) for radionuclides in drinking water (other than radon) [14]*

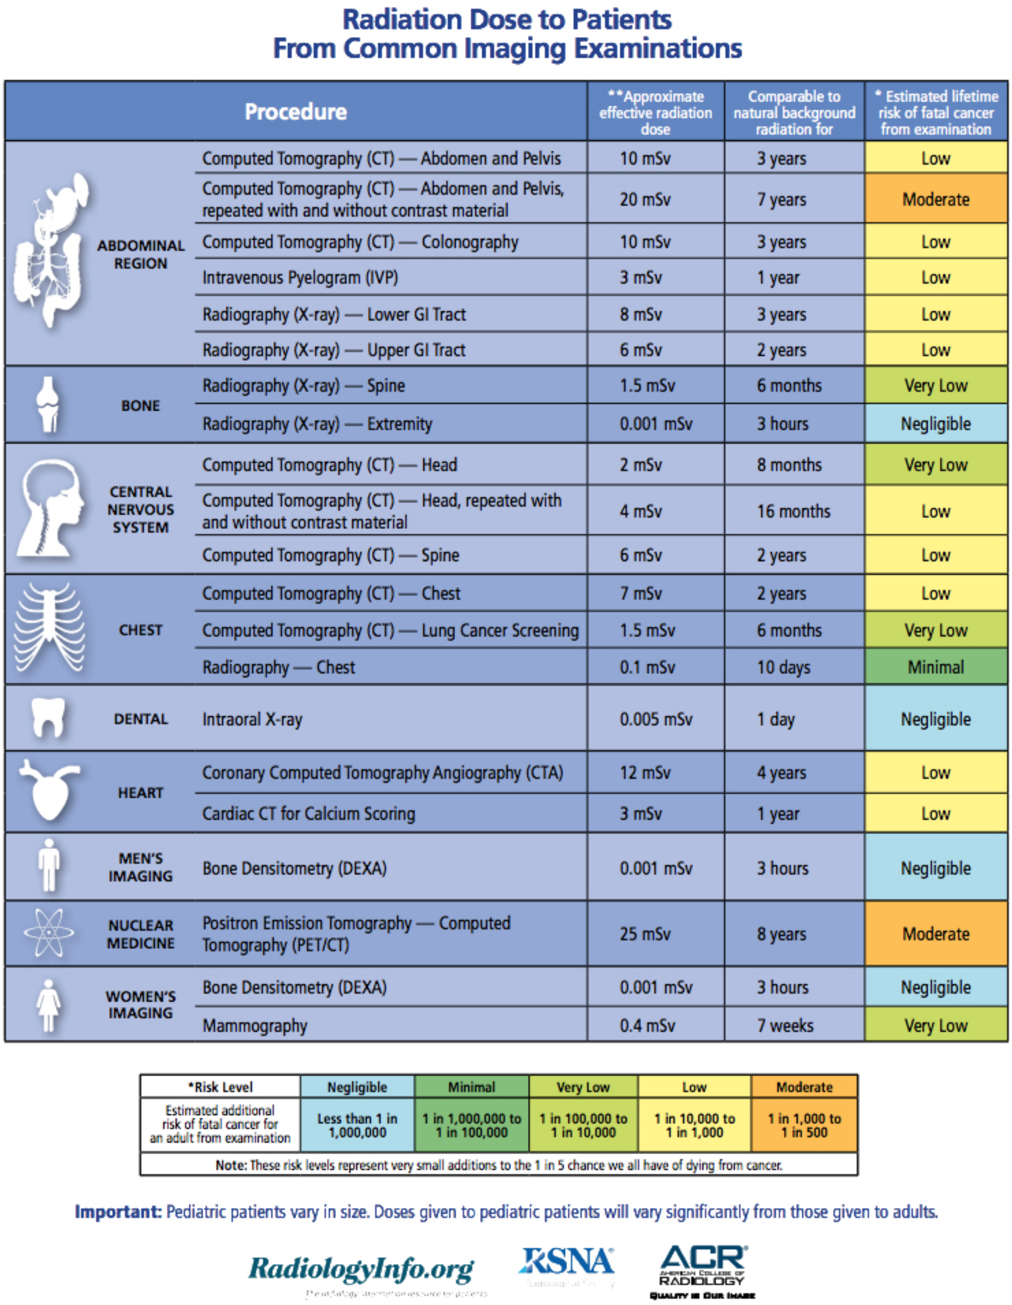
Contaminant	MCL
Combined radium-226 and radium-228	5 pCi/l (0.185 Bq/l)
Gross alpha (excluding Rn and U but including Ra-226)	15 pCi/l (0.555 Bq/l)
Beta particle and photon radioactivity	4 mrem/year (0.04 mSv/year)
Uranium	30 µg/l

Figure 11.137: **European radioactivity permitted level for liquid foodstuffs**

^{40}K is found in relatively large quantities in plants and in food. Its concentration is of the order of $100\,[\text{Bq}\cdot\text{kg}^{-1}]$ for cereals (dry matter) and from 30 to $60\,[\text{Bq}\cdot\text{L}^{-1}]$ for milk. At equilibrium, the human body contains $3,000$ to $6,000$ [Bq] of ^{40}K. Other radioelements, such as ^{210}Pb, the ^{210}Bi and the ^{210}Po are also found in the organism, but in much smaller quantities. In Switzerland, the effective dose due to irradiation by these radioelements varies between 0.2 and $0.5\,[\text{mSv}]$, with the average value $0.35\,[\text{mSv}]$ per year. The global average value of the committed dose according to UNSCEAR (11993 according to holocene calendar) is $0.23\,[\text{mSv}]$ of which nearly 75% is due to ^{40}K.

Here is a table with a summary of some equivalent dose for activities which many humans have to deal with once in their life:



Radiation Dose to Patients
From Common Imaging Examinations

	Procedure	**Approximate effective radiation dose	Comparable to natural background radiation for	* Estimated lifetime risk of fatal cancer from examination
ABDOMINAL REGION	Computed Tomography (CT) — Abdomen and Pelvis	10 mSv	3 years	Low
	Computed Tomography (CT) — Abdomen and Pelvis, repeated with and without contrast material	20 mSv	7 years	Moderate
	Computed Tomography (CT) — Colonography	10 mSv	3 years	Low
	Intravenous Pyelogram (IVP)	3 mSv	1 year	Low
	Radiography (X-ray) — Lower GI Tract	8 mSv	3 years	Low
	Radiography (X-ray) — Upper GI Tract	6 mSv	2 years	Low
BONE	Radiography (X-ray) — Spine	1.5 mSv	6 months	Very Low
	Radiography (X-ray) — Extremity	0.001 mSv	3 hours	Negligible
CENTRAL NERVOUS SYSTEM	Computed Tomography (CT) — Head	2 mSv	8 months	Very Low
	Computed Tomography (CT) — Head, repeated with and without contrast material	4 mSv	16 months	Low
	Computed Tomography (CT) — Spine	6 mSv	2 years	Low
CHEST	Computed Tomography (CT) — Chest	7 mSv	2 years	Low
	Computed Tomography (CT) — Lung Cancer Screening	1.5 mSv	6 months	Very Low
	Radiography — Chest	0.1 mSv	10 days	Minimal
DENTAL	Intraoral X-ray	0.005 mSv	1 day	Negligible
HEART	Coronary Computed Tomography Angiography (CTA)	12 mSv	4 years	Low
	Cardiac CT for Calcium Scoring	3 mSv	1 year	Low
MEN'S IMAGING	Bone Densitometry (DEXA)	0.001 mSv	3 hours	Negligible
NUCLEAR MEDICINE	Positron Emission Tomography — Computed Tomography (PET/CT)	25 mSv	8 years	Moderate
WOMEN'S IMAGING	Bone Densitometry (DEXA)	0.001 mSv	3 hours	Negligible
	Mammography	0.4 mSv	7 weeks	Very Low

*Risk Level	Negligible	Minimal	Very Low	Low	Moderate
Estimated additional risk of fatal cancer for an adult from examination	Less than 1 in 1,000,000	1 in 1,000,000 to 1 in 100,000	1 in 100,000 to 1 in 10,000	1 in 10,000 to 1 in 1,000	1 in 1,000 to 1 in 500

Note: These risk levels represent very small additions to the 1 in 5 chance we all have of dying from cancer.

Important: Pediatric patients vary in size. Doses given to pediatric patients will vary significantly from those given to adults.

Figure 11.138: **Radiation equivalent dose to patients from common imaging examinations**

Remark

Notice that radiation in space takes the form of subatomic particles or ionized atoms mostly from supernovae. Hopefully the actual (but varying) magnetic field and Earth's atmosphere equal to a slab of metal about almost one meter thick. An instrument aboard the Curiosity Mars rover during its 253-day deep-space cruise revealed that the radiation dose received by an astronaut on even the shortest Earth-Mars round trip would be about 0.66 sievert. This amounts is like receiving a whole-body CT scan every five or six days.

And another nice figure more general that the previous one:

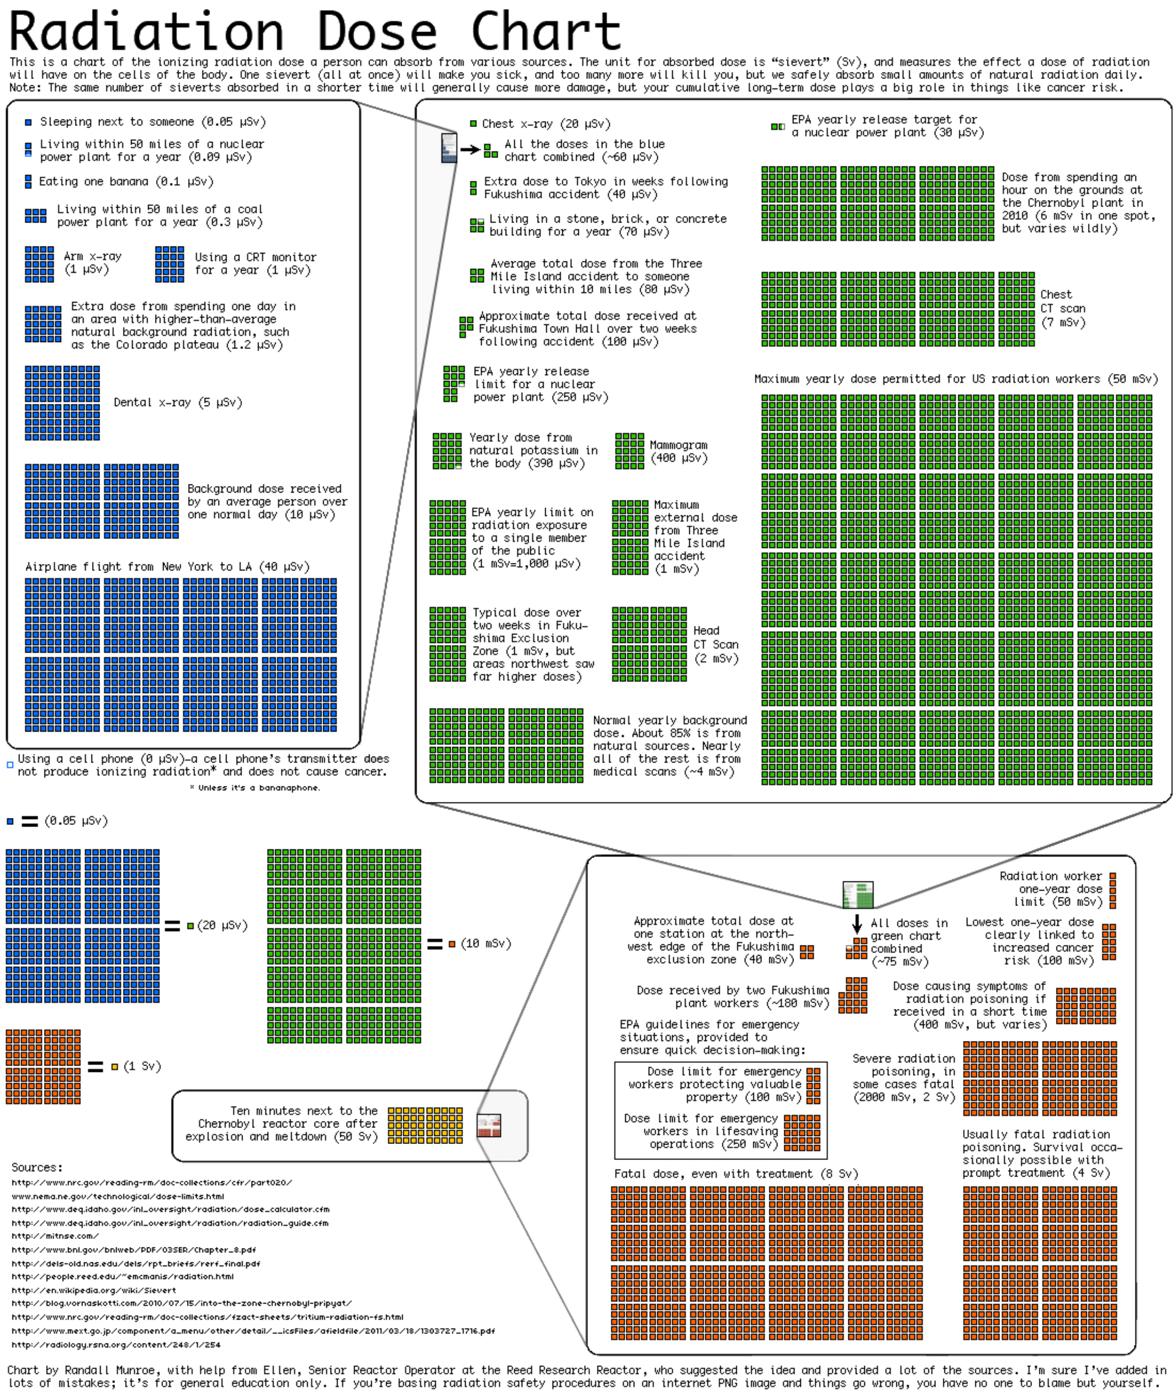


Figure 11.139: Radiation equivalent dose chart

Remark

The highest energy particle ever recorded was an ultra-high-energy cosmic ray detected on 15 October 11991 (holocene calendar). It's energy was estimated as $(3.2 \pm 0.9) \cdot 10^{20}$ [eV], or 51 ± 14 [J]. This is 20 million times more energetic than the highest energy measured in electromagnetic radiation emitted by an extragalactic object. It had 10^{20} (100 quintililon) times the photon energy of visible light, equivalent to a 142 [g] baseball travelling at about 28 $[\mathrm{m} \cdot \mathrm{s}^{-1}]$ (100 $[\mathrm{km} \cdot \mathrm{h}^{-1}]$). Assuming it was a proton, this particle travelled at 0.9999999999999999999999951 of the speed of light.

And finally a last table of common dosimetric values:

Level [mSv]	Duration	Description
0.001	Hourly	Typical cosmic ray dose rate on commercial flights varies from 1 to 10 $[\mu\text{Sv}\cdot\text{h}^{-1}]$, depending on altitude, position and solar sunspot phase.
0.01	Daily	Natural background radiation, including Radon.
0.06	Acute	Chest X-ray
0.09	Acute	Dental panoramic X-ray
0.1	Annual	Average USA dose from comsumer products
0.15	Annual	USA EPA (Environmental Protection Agency) cleanup standard
0.25	Annual	USA NRC (Nuclear Regularotory Agency) cleanup standard for individual sites/sources
0.27	Annual	Average yearly dose from natural cosmic radiation at sea level
0.28	Annual	USA yearly dose from natural terrestrial radiation (0.16-0.64 depending on soil composition)
0.46	Acute	Estimated largest off-site dose from March 28, 11979 (holocene calendar), Three Mile Island nuclear power plant accident.
0.48	Daily	USA NRC public area exposure limit
0.66	Annual	Average USA dose from human-made sources
0.7	Acute	Typical mammogram
1	Annual	Limit of dose from man-made sources to a member of the public who is not a radiation worker in the US and Canada
1.2	Acute	Abdominal X-ray
2	Annual	Head CT (Computed Tomography scan)
3	Annual	USA average dose from all natural sources
4	Annual	Canada CNSC (Canadian Nuclear Safety Commission) maximum occupational dose to a pregnant woman who is designated Nuclear Energy Worker.
5	Annual	USA NRC occupational limit for pregnant women.
7.6	Annual	Natural radiation at Fountainhead Rock Place, Santa Fe (New Mexico)
8	Acute	Chest CT (Computed Tomography scan)
14	Acute	Whole body PET (Positron Emission tomography) scan
25	Annual	Dose received by a satellite shielded by 3 [mm] of aluminium in an elliptic orbit (320 by $32,190$ [km])) passing the Van Allen radiation belts
50	Annual	USA NRC/Canada CNSC occupational limit for designated Nuclear Energy Workers.
150	Annual	USA NRC occupational eye lens exposure limit
170	Acute	Average dose for $187,000$ Chernobyl recovery operation workers in 11986 (holocene calendar)
250	Acute	USA EPA (Environmental Projection Agency) voluntary maximum dose for emergency non-life saving work

Level [mSv]	Duration	Description
400-900	Annual	Unshielded radiation in interplanetary space
$1,000$	Hourly	Level reported during Fukushima I nuclear accidents, in immediate vicinity of reactor
$4,800$	Acute	Median latent dose in humans from radiation poisoning
$5,000$	Acute	Dose fatally received by Harry Daghlian on August 21, 11945 (holocene calendar), at Los Alamos (USA)
$5,000$-$10,000$	Acute	Most commercial electronics can survive this radiation level
$20,000$	Acute	Interplanetary exposure to solar particle event (SPE) of October 11989 (holocene calendar)
$21,000$	Acute	Dose fatally received by Louis Slotin on May 21, 11946 (holocene calendar), at Los Alamos (USA)
$48,500$	Acute	Dose fatally received by Alexandr Zakharov on June 17, 11997 (holocene calendar), at Sarov (Russia)
$60,000$	Acute	Lower bound dose fatally received by Cecil Kelley on December 30, 11958 (holocene calendar), at Los Alamos (USA)
$100,000$	Acute	Estimated dose fatally received by Robert Peabody on July 24, 11964 (holocene calendar), at the United Nuclear Fuels Recovery Plant
$30,000,000$	Acute	Radiation tolerated by Thermococcus gammatolerans, a microbe extremely resistant to radiation

Table 11.22: **Common radiation values**

Remark

A Qantas flight in 12008 (holocene calendar) experienced sudden altitude drops due to a cosmic ray-induced fault in its flight computer and in 2003, a Belgian election saw a candidate receive $4,096$ extra votes - traced back to a cosmic ray flipping a bit in the voting machine. Even video game glitches and modern cars issues but also and pacemaker malfunctions have been linked to cosmic ray interference.

11.4.4 Liquid Drop Model of Nucleus

At the beginning of the 121st century (holocene calendar) there is no general theory that underlies all the properties experimentally discovered relative to the nuclei. The nuclei has multiple facets which to this day can not be reconciled in a single theory (quantum chromodynamics not being able to model the nucleus).

The most accurate information on the radii of nuclear nuclei and more generally on the charge density of nuclei comes from measurements of electron scattering. The latter, considered to date as elementary particles, do not undergo the strong nuclear force guaranteeing the cohesion of the nucleus and can be considered in theoretical treatments as punctual.

Here is basically the state of our knowledge about the nuclei at the beginning of the 121st century (holocene calendar):

1. The nucleon-nucleon nuclear interaction potential is a priori attractive at the nucleus level but sometimes also repulsive if the distance becomes too small between its constituents.
2. The nuclear interaction is small in scope and presents a phenomenon of saturation such as if each nucleon were directly linked only to its direct neighbours (after having bound to a few nucleons its possibility of binding is exhausted), unlike the electrostatic force.
3. The nuclear force is a priori independent of the electric charge. It acts as well between neutrons, as between neutrons and protons and protons-protons.

In the naive model that we will study here (which explains quite well the binding energy of the nucleons), the nucleus can be assimilated to a nuclear liquid drop in a first spherical approximation and incompressible, of constant density by volume:

$$\frac{A}{\frac{4}{3}\pi R^3}=c^{te} \tag{11.4.380}$$

where A still represents in the framework of this section the number of mass.

Which leads to:

$$R=\left(\frac{1}{\frac{4}{3}\pi c^{te}}\right)^{1/3}A^{1/3}:=R_0A^{1/3} \tag{11.4.381}$$

with:

$$R_0\cong 1.17\cdot 10^{-15}\,[\text{m}] \tag{11.4.382}$$

However, the modelling is already failing here because the isotopes of mercury have larger radii than those predicted in the framework of this model and this with strong variations (these variations being irreconcilable with the regular evolution of a drop as a function of its number of constituents). There are even cases where by removing neutrons, the radius of the nucleus increases very significantly!

✍**Example:**

The practical problem to obtaining fusion, whether in power production or more generally, has its origin in the Coulomb repulsion, which inhibits two nuclei getting close enough together to fuse. This is given by the Coulomb potential

$$U_{\text{C}}=\frac{1}{4\pi\varepsilon_0}\frac{ZZ'e^2}{R+R'}$$

where Z and Z' are the atomic numbers of the two nuclei and R and R' are their effective radii. The quantity $(R+R')$ is therefore classically the distance of closest approach. Recalling that for medium and heavy nuclei $R\cong 1.2A^{\frac{1}{3}}\;[\text{fm}]$, we have:

$$U_{\text{C}}=\left(\frac{e^2}{4\pi\varepsilon_0\hbar c}\right)\frac{\hbar cZZ'}{1.2\left[A^{1/3}+(A')^{1/3}\right]\;[\text{fm}]}=1.198\frac{ZZ'}{A^{1/3}+(A')^{1/3}}\;[\text{MeV}]$$

If, for illustration, we set $A\cong A'\cong 2Z\cong 2Z'$, then:

$$U_{\text{C}}\cong 0.15A^{\frac{5}{3}}\;[\text{MeV}]$$

Thus, for example, with $A\cong 8, U_{\text{C}}\cong 4.8\,[\text{MeV}]$ and this energy has to be supplied to overcome the Coulomb barrier.

This is a relatively small amount of energy to supply and it might be thought that it could be achieved by simply colliding two accelerated beams of light nuclei, but in practice nearly all the particles would be elastically scattered. The only practical way is to heat a confined mixture of the nuclei to supply enough thermal energy to overcome the Coulomb barrier. The temperature necessary may be estimated from the relation $E=kT$. For an energy of 4.8 [MeV], this implies a temperature of $5.6\cdot 10^{10}$ [K]. This is well above the typical temperature of 10^8 [K] found in stellar interiors. It is also the major hurdle to be overcome in achieving a controlled fusion reaction in a reactor, as we shall see later.

Fusion actually occurs at a lower temperature than this estimate due to a combination of two reasons. The first and most important is the phenomenon of quantum tunnelling, which means that the full height of the Coulomb barrier does not have to be overcome. The other reason that fusion occurs at a lower temperature than expected is that a collection of nuclei at a given mean temperature, whether in stars or elsewhere, will have a Maxwellian distribution of energies about the mean and so there will be some with energies substantially higher than the mean energy.

Let us now examine the different energies involved. We will construct on the path the famous semi-empirical formula of von Weizsäcker.

11.4.4.1 Volumetric binding energy

The strong nuclear interaction confers a "volumetric binding energy" of the form:

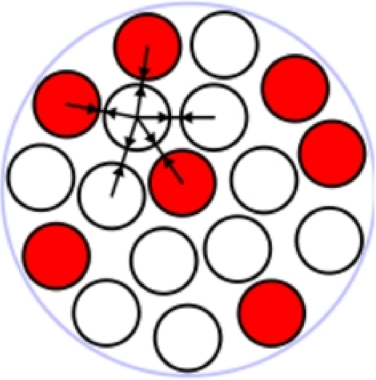
$$E_V = a_V A \quad (11.4.383)$$

named the "volume term", where is a_V is a predetermined constant (in a first time...) experimentally being approximately equal to:

$$a_V \cong 14\,[\text{MeV}] \quad (11.4.384)$$

and we will prove how to theoretically determine its value a little further below during our determination of the "Pauli energy".

The schematic representation of the idea of "volumetric binding energy" (with directly related neighbours) gives:



where the colors (red, white) are there only to illustrate the set of binding energies that we will also see later. However, these are obviously nucleons (protons and neutrons).

11.4.4.2 Superficial binding energy

The nucleons close to the outer surface of the nucleus are less linked via the strong interaction than the deep nucleons since they have fewer direct neighbours. It is therefore necessary to depart from the idea that each constituent has the same volumetric binding energy and subtract from the totality of the latter a "superficial binding energy" proportional to the surface of the nucleus which is:

$$S = 4\pi R^2 = 4\pi (R_0 A^{1/3})^2 = 4\pi R_0^2 A^{2/3} \quad (11.4.385)$$

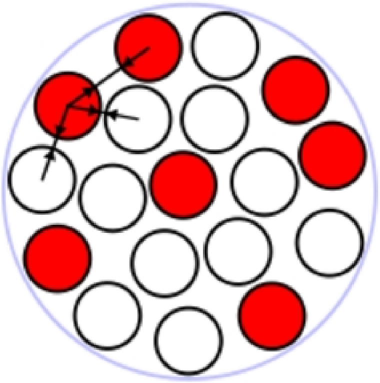
We then have for the superficial energy:

$$E_S = -a_S A^{2/3} \quad (11.4.386)$$

named the "surface term" where a_s is a constant determined experimentally as being approximately equal to:

$$a_S \cong 17\,[\text{MeV}] \quad (11.4.387)$$

The schematic representation of the idea of "superficial binding energy" (with directly related neighbours) gives:



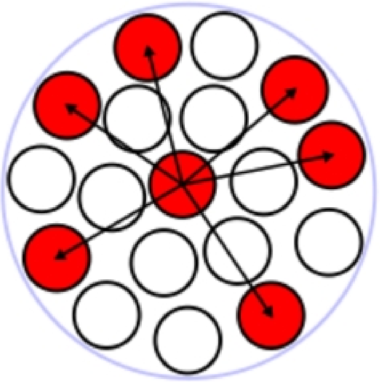
It is this term that makes we think to a liquid drop. Indeed, in a liquid drop, the forces are also assumed to be short-range (Van der Waals forces), and thus saturate what immediately causes a surface tension.

We thus have up to now the total potential binding energy of the nucleus which is given by a part of the "von Weizsäcker semi-empirical formula" (or "Bethe-Weizsäcker formula"):

$$E_n=E_V+E_S=a_VA-a_SA^{2/3} \tag{11.4.388}$$

11.4.4.3 Coulomb electrostatic repulsive energy

We must also take into account the usual "electrostatic binding energy" or "Coulomb binding energy" which results from the electrostatic repulsion force between protons:



As it is repulsive, it decreases the binding energy (so this will be a negative term). To get the electrical potential energy, let us recall that we have already proved in the section of Astronomy that for the gravitational energy we had:

$$E_p=-\frac{3}{5}\frac{GM^2}{R} \tag{11.4.389}$$

It then comes immediately for the electrostatic (coulombian) case:

$$E_{p,C}=-\frac{3}{5}\frac{1}{4\pi\varepsilon_0}\frac{(Ze)^2}{R}=-\frac{3e^2}{20\pi\varepsilon_0}\frac{Z^2}{R}=-\frac{3e^2}{20\pi\varepsilon_0 R_0}\frac{Z^2}{A^{1/3}}=-a_C\frac{Z^2}{A^{1/3}} \tag{11.4.390}$$

named the "Coulomb term" with the computable constant:

$$a_C\cong 0.72\,[\text{MeV}] \tag{11.4.391}$$

We thus have up to now the total potential binding energy of the nucleus which is given by a part of the von Weizsäcker semi-empirical formula:

$$E_n=E_V+E_S+E_{p,C}=a_VA-a_SA^{2/3}-a_C\frac{Z^2}{A^{1/3}} \tag{11.4.392}$$

11.4.4.4 Energy of asymmetry (Pauli energy)

This energy term is inspired by the model of the nucleus based on the Fermi gas where we consider the nucleus as a set of A (quasi) free nucleons enclosed in a rectangular box having the dimensions of the nucleus and respecting quantization rules (what experiment seems to confirm). Quantum physics is therefore not unique to the atomic world but also to the structure of the nucleus (we could suspect it).

We have then proved in the section of Electrokinetics (in our study of the theory of bands page 4289) that under certain (strong!) precise conditions, the maximum number of states in a spherical volume was given for fermions by:

$$n(k)=\frac{k_F^3}{3\pi^2}V \tag{11.4.393}$$

where for recall k_F is the Fermi wave number that it is more usage in the nuclear field to write in another way using the de Broglie relation (see section Wave Quantum Physics page 4749):

$$p=\hbar k \tag{11.4.394}$$

Thus:

$$n(k)=\frac{p_F^3}{3\pi^2\hbar^3}V \tag{11.4.395}$$

We can then have a number of neutrons (N) and a number of protons (Z) respectively equal at most to:

$$N=\frac{(p_F^n)^3}{3\pi^2\hbar^3}V\qquad Z=\frac{(p_F^p)^3}{3\pi^2\hbar^3}V \tag{11.4.396}$$

Knowing the expression of the volume of a nucleus, under the hypothesis of modelling by a spherical and incompressible liquid drop, we have explicitly:

$$n=n(p)=\frac{p_F^3}{3\pi^2\hbar^3}V=\frac{p_F^3}{3\pi^2\hbar^3}\frac{4}{3}\pi R^3=\frac{4p_F^3}{9\pi\hbar^3}(R_0A^{1/3})^3=\frac{4p_F^3A}{9\pi\hbar^3}R_0^3 \tag{11.4.397}$$

We have, therefore, in extenso:

$$p_F=\left(\frac{9\pi\hbar^3}{4A}\frac{n}{R_0^3}\right)^{1/3}=\left(\frac{9\pi}{4A}n\right)^{1/3}\frac{\hbar}{R_0} \tag{11.4.398}$$

Assuming that:

$$n=Z=N=A/2 \tag{11.4.399}$$

We then have for the linear momentum (of the nucleus considered as (quasi) free in the nucleus ... by construction of the assumptions of the theory of bands):

$$p=p_F^n=p_F^p=\left(\frac{9\pi}{4A}\frac{A}{2}\right)^{1/3}\frac{\hbar}{R_0}=\left(\frac{9\pi}{8}\right)^{1/3}\frac{\hbar}{R_0} \tag{11.4.400}$$

Knowing experimentally R_0 (of the order of $R_0=1.21$ [fm]), we extract a numerical value of it that shows that the nucleons move freely within the nucleus with quite large momenta! From this we can derive, taking the classical formulation of energy (hence non-relativistic), that the state of maximum energy state (fermi level of the nucleus) is then:

$$E_F=\frac{1}{2}mv^2=\frac{1}{2}\frac{p_F^2}{m}\cong 33\,[\text{MeV}] \tag{11.4.401}$$

This being done, let us now calculate the average kinetic energy per nucleon. We then have:

$$\begin{aligned}\langle E_c\rangle=\frac{\sum E_c}{N}&=\frac{\displaystyle\int_0^{E_F}E_c\mathrm{d}n}{\dfrac{p_F^3}{3\pi^2\hbar^3}V}=\frac{\displaystyle\int_0^{E_F}E_c\frac{\mathrm{d}n}{\mathrm{d}p}\mathrm{d}p}{\dfrac{p_F^3}{3\pi^2\hbar^3}V}=\frac{\displaystyle\int_0^{p_F}E_c\left(\frac{3p^2}{3\pi^2\hbar^3}V\right)\mathrm{d}p}{\dfrac{p_F^3}{3\pi^2\hbar^3}V}=\frac{\displaystyle 3\int_0^{p_F}E_cp^2\mathrm{d}p}{p_F^3}\\&=\frac{\displaystyle 3\int_0^{p_F}\frac{p^2}{2m}p^2\mathrm{d}p}{p_F^3}=\frac{\displaystyle\frac{3}{2m}\int_0^{p_F}p^4\mathrm{d}p}{p_F^3}=\frac{\dfrac{3}{2m}\dfrac{1}{5}p_F^5}{p_F^3}=\frac{3}{5}\frac{p_F^2}{2m}\cong 20\,[\text{MeV}]\end{aligned} \tag{11.4.402}$$

The total kinetic energy of the nucleus is then (by approximating the mass of the neutron as being equal to that of the proton):

$$E_c=N\cdot\langle E_c^n\rangle+Z\cdot\langle E_c^p\rangle=N\frac{3}{5}\frac{(p_F^n)^2}{2m_n}+Z\frac{3}{5}\frac{(p_F^p)^2}{2m_p} \tag{11.4.403}$$

However, as we have proved above that:

$$N=\frac{(p_F^n)^3}{3\pi^2\hbar^3}V\qquad Z=\frac{(p_F^p)^3}{3\pi^2\hbar^3}V \tag{11.4.404}$$

Then it comes:

$$\begin{aligned}E_c=&N\frac{3}{5}\frac{\left(\dfrac{N3\pi^2\hbar^3}{V}\right)^{2/3}}{2m_n}+Z\frac{3}{5}\frac{\left(\dfrac{Z3\pi^2\hbar^3}{V}\right)^{2/3}}{2m_p}=\frac{3\hbar^2}{10}\left(\frac{3\pi^2}{V}\right)^{2/3}\left[\frac{N^{5/3}}{m_n}+\frac{Z^{5/3}}{m_p}\right]\\&=\frac{3\hbar^2}{10}\left(\frac{3\pi^2}{\frac{4}{3}\pi(R_0A^{1/3})^3}\right)^{2/3}\left[\frac{N^{5/3}}{m_n}+\frac{Z^{5/3}}{m_p}\right]=\frac{3\hbar^2}{10}\left(\frac{3\pi^2}{\frac{4}{3}\pi R_0^3A}\right)^{2/3}\left[\frac{N^{5/3}}{m_n}+\frac{Z^{5/3}}{m_p}\right]\\&=\frac{3\hbar^2}{10R_0^2}\left(\frac{9\pi}{4A}\right)^{2/3}\left[\frac{N^{5/3}}{m_n}+\frac{Z^{5/3}}{m_p}\right]\end{aligned} \tag{11.4.405}$$

And if we put:

$$m_n \cong m_p \cong M \tag{11.4.406}$$

Then we have:

$$E_c = \frac{3\hbar^2}{10MR_0^2}\left(\frac{9\pi}{4}\right)^{2/3}\left[\frac{N^{5/3}+Z^{5/3}}{A^{2/3}}\right] \tag{11.4.407}$$

We know that:

$$E_c = E_{\text{tot}} - E_p \tag{11.4.408}$$

We will seek to get a similar relation by making a clever approximation. For this, let us recall that $A = Z + N$, we will consider the ratio:

$$I = \frac{N-Z}{A} = \frac{A-2Z}{A} = 1 - 2\frac{Z}{A} \tag{11.4.409}$$

Which will be supposed small ... We have then:

$$N^{5/3} + Z^{5/3} = (A-Z)^{5/3} + Z^{5/3} = A^{5/3}\left[\left(1-\frac{Z}{A}\right)^{5/3} + \left(\frac{Z}{A}\right)^{5/3}\right] \tag{11.4.410}$$

We have also:

$$\frac{Z}{A} = \frac{1-I}{2} \tag{11.4.411}$$

It then comes:

$$\begin{aligned} N^{5/3} + Z^{5/3} &= A^{5/3}\left[\left(1-\frac{Z}{A}\right)^{5/3} + \left(\frac{Z}{A}\right)^{5/3}\right] = A^{5/3}\left[\left(1-\frac{1-I}{2}\right)^{5/3} + \left(\frac{1-I}{2}\right)^{5/3}\right] \\ &= A^{5/3}\left[\left(\frac{1+I}{2}\right)^{5/3} + \left(\frac{1-I}{2}\right)^{5/3}\right] = \left(\frac{A}{2}\right)^{5/3}\left[(1+I)^{5/3} + (1-I)^{5/3}\right] \end{aligned} \tag{11.4.412}$$

The Taylor's second-order expansion in I gives:

$$\begin{aligned} (1+I)^{5/3} &\cong 1 + \frac{5}{3}I + \frac{5}{9}I^2 + \ldots \\ (1-I)^{5/3} &\cong 1 + -\frac{5}{3}I + \frac{5}{9}I^2 - \ldots \end{aligned} \tag{11.4.413}$$

and therefore:

$$N^{5/3} + Z^{5/3} \cong \left(\frac{A}{2}\right)^{5/3} 2\left[1 + \frac{5}{9}I^2\right] = \left(\frac{A}{2}\right)^{5/3} 2\left[1 + \frac{5}{9}\frac{(N-Z)^2}{A^2}\right] \tag{11.4.414}$$

We then have:

$$\begin{aligned}E_c&=\frac{3\hbar^2}{10MR_0^2}\left(\frac{9\pi}{4}\right)^{2/3}\frac{1}{A^{2/3}}\left(\frac{A}{2}\right)^{5/3}2\left[1+\frac{5}{9}\frac{(N-Z)^2}{A^2}\right]\\&=\frac{3\hbar^2}{5MR_0^2}\left(\frac{9\pi}{4}\right)^{2/3}\frac{1}{A^{5/3}}\left(\frac{A}{2}\right)^{5/3}\left[A+\frac{5}{9}\frac{(N-Z)^2}{A}\right]\\&=\frac{3\hbar^2}{5MR_0^2}\left(\frac{9\pi}{4}\right)^{2/3}\left(\frac{1}{2}\right)^{5/3}\left[A+\frac{5}{9}\frac{(N-Z)^2}{A}\right]\\&=\frac{3\hbar^2}{5MR_0^2}(9\pi)^{2/3}\left(\frac{1}{2^2}\right)^{2/3}\frac{1}{2^{5/3}}\left[A+\frac{5}{9}\frac{(N-Z)^2}{A}\right]\\&=\frac{3\hbar^2}{5MR_0^2}(9\pi)^{2/3}\frac{1}{2^{4/3}}\frac{1}{2^{5/3}}\left[A+\frac{5}{9}\frac{(N-Z)^2}{A}\right]\\&=\frac{3\hbar^2}{5MR_0^2}\frac{(9\pi)^{2/3}}{2^3}\left[A+\frac{5}{9}\frac{(N-Z)^2}{A}\right]=a_VA+a_A\frac{(N-Z)^2}{A}=E_T-E_p\end{aligned}\tag{11.4.415}$$

Thus we have kill two birds with one stone: on the one hand we have identified the value of the coefficient of the term of volumetric bonding energy a_V as we promised earlier and on the other hand we deduce from it the term energy of asymmetry:

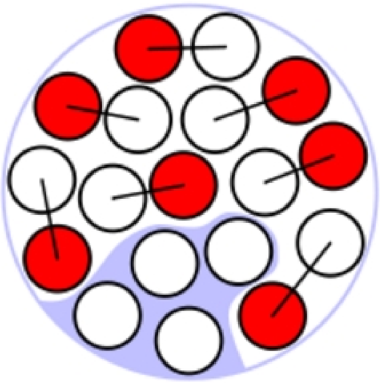
$$E_p=-a_A\frac{(N-Z)^2}{A}=E_A\tag{11.4.416}$$

We then have a term of potential energy which appears in the form:

$$E_A=-a_A\frac{(N-Z)^2}{A}\tag{11.4.417}$$

with:

$$a_A\cong 21\,[\text{MeV}]\tag{11.4.418}$$



Since this term is zero when the number of neutrons is equal to the number of protons, we can understand the origin of the valley of stability a little bit better.

We thus have up to now the total potential binding energy of the nucleus which is given by a part of the on Weizsäcker semi-empirical formula:

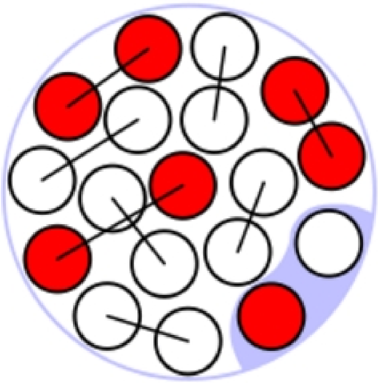
$$E_n=E_V+E_S+E_{p,C}+E_A=a_VA-a_SA^{2/3}-a_C\frac{Z^2}{A^{1/3}}-a_A\frac{(N-Z)^2}{A}\tag{11.4.419}$$

11.4.4.5 Pairing Energy

A systematic study of nuclei shows that they are more stable when they consist of an even number of neutrons or protons. Empirically, we write this fact by subtracting the following pairing energy:

$$E_p = -\frac{\delta}{\sqrt{A}} \tag{11.4.420}$$

where δ is equal to -11.2 [MeV] if Z and N are even, 0 if A is odd and 11.2 [MeV] if Z and N are odd.



Finally, we have the total potential binding energy of the nucleus given by the "semi-empirical formula of von Weizsäcker" or also named "semi-empirical mass formula" (SEMF):

$$\boxed{E_n = E_V + E_S + E_{p,C} + E_A + E_p = a_V A - a_S A^{2/3} - a_C \frac{Z^2}{A^{1/3}} - a_A \frac{(N-Z)^2}{A} - \frac{\delta}{\sqrt{A}}} \tag{11.4.421}$$

that we also found in some textbooks in the following form:

$$\boxed{E_n = \underbrace{a_V A}_{\text{volume}} - \underbrace{a_S A^{2/3}}_{\text{sueprficial}} - \underbrace{a_C Z^2 A^{-1/3}}_{\text{coulomb}} - \underbrace{a_A \frac{(A-2Z)^2}{A}}_{\text{asymmetry}} - \underbrace{a_p A^{-1/2}}_{\text{pairing}}} \tag{11.4.422}$$

The mass energy of the nucleus can then be written:

$$\boxed{M_A c^2 = m_n (A-Z)c^2 + Z m_p c^2 - \left(a_V A - a_S A^{2/3} - a_C \frac{Z^2}{A^{1/3}} - a_A \frac{(A-2Z)^2}{A} - \frac{\delta}{\sqrt{A}}\right)} \tag{11.4.423}$$

Remark

The numerical values of the constants are not yet internationally standardized and we can find in the literature several sets of different values.

Let us notice that the model of the liquid drop also fails to explain that the elements of fissions are not of symmetrical size (the model of liquid drop favouring a fission in two cores of the same size).

We have for the theoretical model above the corresponding graphical representation:

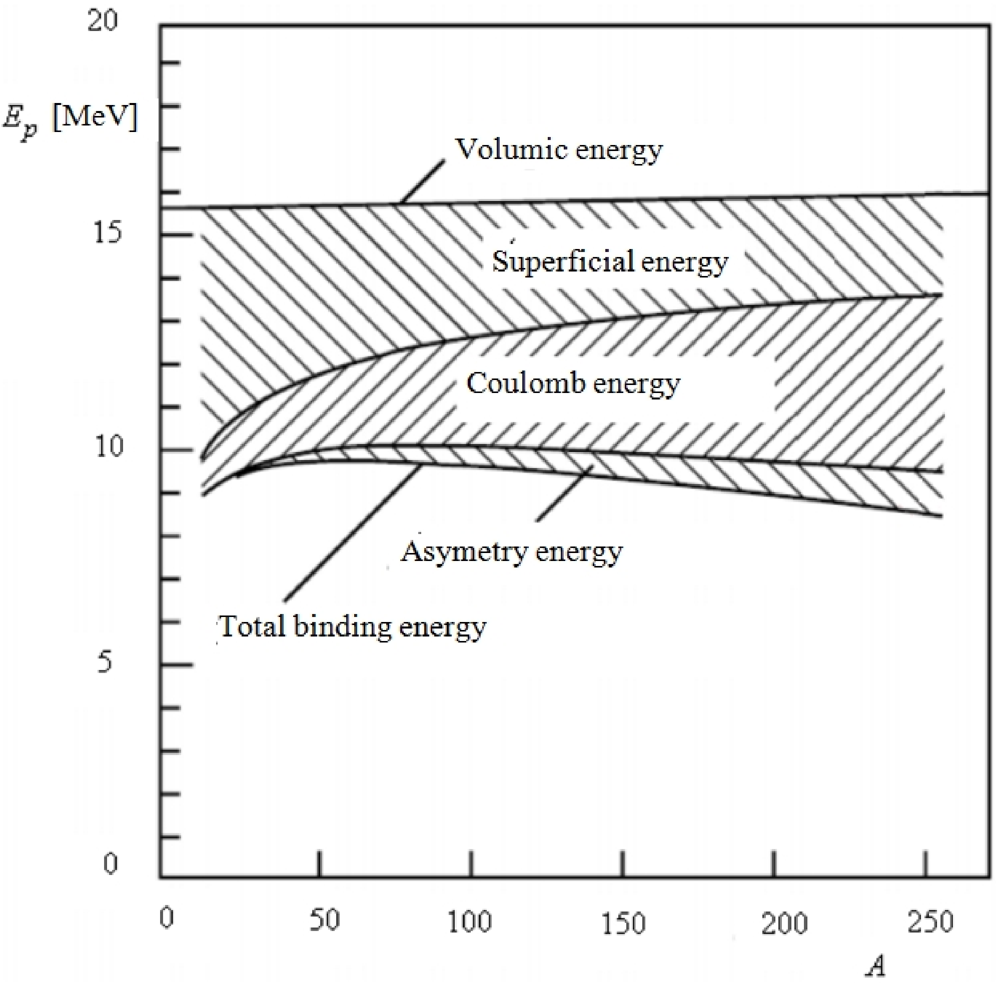


Figure 11.140: Schematic representation of the semi-empirical formula of von Weizsäcker

We see above that the average binding energy can be considered very approximately as constant. This can also be interpreted as a force exerted by a limited number of partners. We speak of "saturating force". By "saturating force" we mean that for a given force there is a limit to the number of nucleons placed side by side from which the addition of a nucleon only provides a constant additional binding energy. It is therefore the close neighbours who bring the force to its level, the arrival of new neighbours only subsequently supporting the average value reached. This is why we say that the energy of volume is calculated only with direct neighbours and that the model is also assimilable to a liquid drop (the molecules of a drop of water being sensitive only to directly adjacent molecules).

This approach also explains the increase in binding energy per nucleon for low masses. Indeed, consider a so-named force of type "F2". We have then the construction of the nuclei thanks to this type of geometry:

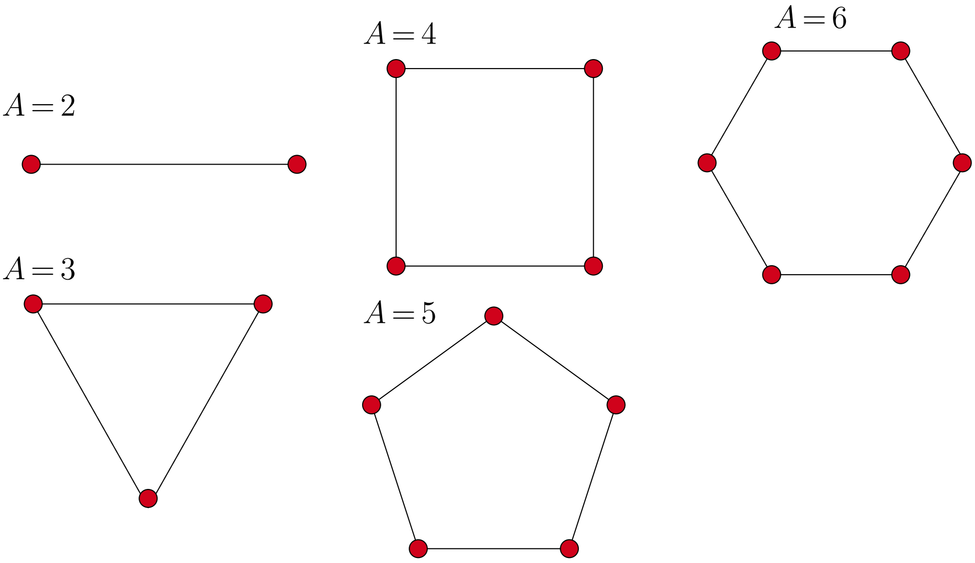

Figure 11.141: **Schematic representation of the saturating force of type F2**

Each nucleon has two bonds (except for the case $A=2$ which explains that the binding energy increases for the small A) and exhaust the possibilities of the force of the F2 type. This limitation imposes no restrictions on the size of the objects to be built and we can imagine constructions as large as we want, stabilized by this type of force.

If we calculate the total binding energy, we will have $1 \cdot E_p$ for $A=2$, where E_p is the potential binding energy provided by a bond. Similarly, we will have $3 \cdot E_p$ for $A=3$, $4 \cdot E_p$ for $A=4$, $5 \cdot E_p$ for $A=5$, and so on... The binding energy per nucleon will then be $E_p/2$ for $A=2$ and then E_p for all the other masses, for a constant force of type F2. Therefore this force saturates beyond $A=2$.

If we take a F3 force type, we will have:

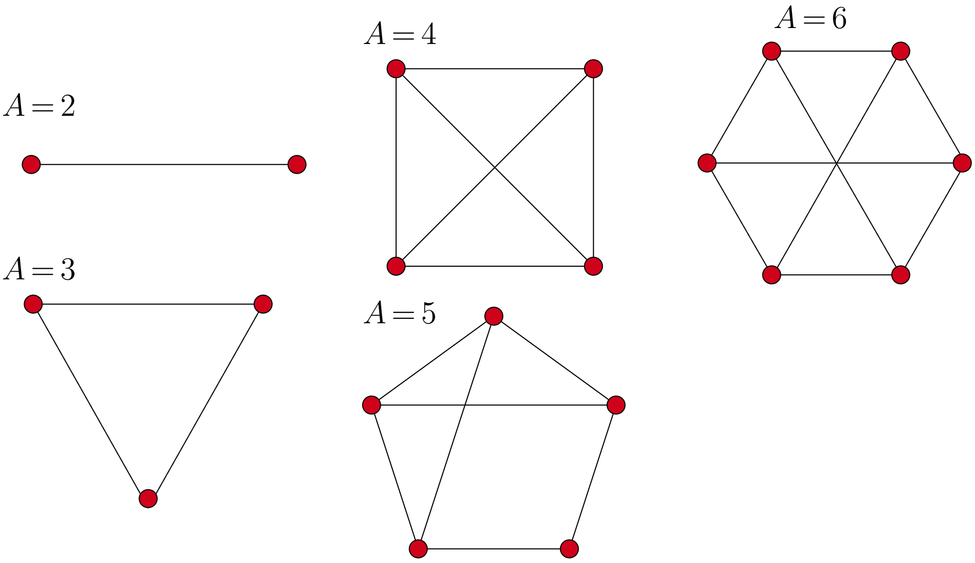

Figure 11.142: **Schematic representation of the saturating force of type F3**

If we calculate the total binding energy, we will have $1 \cdot E_p$ for $A=2$, where E_p still remains the potential binding energy provided by a bond. Similarly, we will have the $3 \cdot E_p$ for $A=3$, $6 \cdot E_p$ for $A=4$, $7 \cdot E_p$ for $A=5$, etc.

Remark

We notice that for $A=5$ only 2 bounds can start from the last vertex of the pentagon, otherwise another vertex of the pentagon would have 4 bounds and not 3 (force F3).

The asymptotic value of the binding energy per nucleon will then be $1.5 \cdot E_p$ for all masses greater than $A=3$, for a constant force F3. Therefore this force saturates beyond $A=3$.

We can continue so on with nuclei that include more and more nucleons.

In the particular case of a force that could interact with all other surrounding nucleons, there will be as we have proved in the section of Graph Theory for complete graphs ("graph size"):

$$\frac{A(A-1)}{2} \tag{11.4.424}$$

bounds and thus a behaviour in $(A-1)/2$ in the average binding energy (since it is simply a matter of dividing by A the number of bonds). Thus, in the classical case, the binding energy would only increase what is not compatible with the experiment.

✍**Example:**

Let us see some applications of this model starting by examining the predictions on the fission of the uranium ${}^{236}_{92}\text{U}$ in two equal sub-products in mass and in charge:

$${}^{A}_{Z}\text{X} \rightarrow 2\,{}^{A/2}_{Z/2}\text{X} \tag{11.4.425}$$

and this by using the liquid drop model by neglecting the terms of asymmetry and pairing energy.

For this, let us recall that:

$$E_p(A,Z) = a_V A - a_S A^{2/3} - a_C \frac{Z^2}{A^{1/3}} - a_A \frac{(A-2Z)^2}{A} - \frac{\delta}{\sqrt{A}} \tag{11.4.426}$$

and we will take as values of the constants:

$$\begin{aligned} a_V &\cong 15.85\,[\text{MeV}]\\ a_S &\cong 18.34\,[\text{MeV}]\\ a_C &\cong 0.71\,[\text{MeV}]\\ a_A &\cong 23.21\,[\text{MeV}]\\ \delta &\cong 12\,[\text{MeV}] \end{aligned} \tag{11.4.427}$$

Let us evaluate the difference of energy between on the one hand the 2 nuclei resulting from the fission and on the other hand the starting nucleus.

We have then:

$$\begin{aligned}\Delta E &= 2M\left({}^{A/2}_{Z/2}X_f\right)c^2 - M\left({}^{A}_{Z}X_m\right)c^2\\ &\cong 2\left(a_V A_f - a_S A_f^{2/3} - a_C\frac{Z_f^2}{A_f^{1/3}}\right) - \left(a_V A_m - a_S A_m^{2/3} - a_C\frac{Z_m^2}{A_m^{1/3}}\right)\end{aligned} \tag{11.4.428}$$

as:

$$2a_V A_f - a_V A_m = a_V\left(2A_f - A_m\right) = a_V\left(2A_f - 2A_f\right) = 0 \tag{11.4.429}$$

The development is simplified in:

$$\begin{aligned}\Delta E &= 2\left(-a_S A_f^{2/3} - a_C\frac{Z_f^2}{A_f^{1/3}}\right) - \left(-a_S A_m^{2/3} - a_C\frac{Z_m^2}{A_m^{1/3}}\right) = a_S\left(A_m^{2/3} - 2A_f^{2/3}\right) + a_C\left(\frac{Z_m^2}{A_m^{1/3}} - 2\frac{Z_f^2}{A_f^{1/3}}\right)\\ &= a_S\left(A_m^{2/3} - 2\left(\frac{A_m}{2}\right)^{2/3}\right) + a_C\left(\frac{Z_m^2}{A_m^{1/3}} - 2\frac{\left(\frac{Z_m}{2}\right)^2}{\left(\frac{A_m}{2}\right)^{1/3}}\right)\\ &= a_S A_m^{2/3}\left(1 - 2\cdot 2^{-2/3}\right) + a_C\frac{Z_m^2}{A_m^{1/3}}\left(1 - 2\frac{\left(\frac{1}{2}\right)^2}{\left(\frac{1}{2}\right)^{1/3}}\right)\\ &= a_S A_m^{2/3}\left(1 - 2^{1/3}\right) + a_C\frac{Z_m^2}{A_m^{1/3}}\left(1 - 2\cdot\frac{2^{-2}}{2^{-1/3}}\right) = a_S A_m^{2/3}\left(1 - 2^{1/3}\right) + a_C\frac{Z_m^2}{A_m^{1/3}}\left(1 - 2^{-2/3}\right)\end{aligned} \tag{11.4.430}$$

If there is fission, we will have $\Delta E \geq 0$, therefore:

$$a_S A_m^{2/3}\left(1 - 2^{1/3}\right) \geq -a_C\frac{Z_m^2}{A_m^{1/3}}\left(1 - 2^{-2/3}\right) \tag{11.4.431}$$

thus:

$$\frac{a_S\left(1 - 2^{1/3}\right)}{a_C\left(1 - 2^{-2/3}\right)} \geq -\frac{Z_m^2}{A_m} \tag{11.4.432}$$

Or rearranged:

$$\frac{Z_m^2}{A_m} \geq \frac{a_S\left(1 - 2^{1/3}\right)}{a_C\left(1 - 2^{-2/3}\right)} \tag{11.4.433}$$

Either by putting the constants, it gives:

$$\frac{Z_m^2}{A_m} \geq 18 \tag{11.4.434}$$

But for ${}^{236}_{92}\text{U}$, we have:

$$\frac{Z^2}{A_m} = \frac{92^2}{236} = 36 > 18 \tag{11.4.435}$$

So according to the above result ${}^{236}_{92}\text{U}$ can fission symmetrically but this is not the case in the experiment, because in reality we have:

$${}^{236}\text{U} + n \rightarrow {}^{236}\text{U}^* \rightarrow {}^{140}\text{Xe} + {}^{94}\text{Sr} + 2n \tag{11.4.436}$$

There is, however, another possible theoretical approach which gives a result more in agreement with the experiment. Indeed, we can imagine that a nucleus can undergo fission if the force derived from the superficial energy is exactly compensated by the Coulomb force.

In the end, we will compare the ratio Z^2/A_m with the result we will get with the new approach.

Let us first recall that we have seen in the section of Electrostatics (among others...) that the electrostatic force derives from the electrostatic potential:

$$F=\left|-\frac{\mathrm{d}U}{\mathrm{d}R}\right|=\left|-\frac{1}{e}\frac{\mathrm{d}E_p}{\mathrm{d}R}\right| \tag{11.4.437}$$

where the radius R has in our case the value of the nuclear radius, with for recall:

$$R=R_0A^{1/3} \tag{11.4.438}$$

We then have:

$$\begin{gathered}U_S(R)=-\frac{1}{e}a_SA^{2/3}=-\frac{1}{e}a_S\left(\frac{R}{R_0}\right)^2=-\frac{1}{e}\frac{a_S}{R_0^2}R^2\\U_C(R)=-\frac{1}{e}a_CZ^2A^{-1/3}=-\frac{1}{e}a_CZ^2\left(\frac{R}{R_0}\right)^{-1}=-\frac{1}{e}a_CZ^2R_0R^{-1}\end{gathered} \tag{11.4.439}$$

Therefore:

$$\begin{gathered}F_S(R)=\left|-\frac{\mathrm{d}}{\mathrm{d}R}\left(-\frac{a_S}{eR_0^2}R^2\right)\right|=\left|\frac{2a_S}{eR_0^2}R\right|=\frac{2a_S}{|e|R_0^2}R_0A^{1/3}=\frac{2a_S}{|e|R_0}A^{1/3}\\F_C(R)=\left|-\frac{\mathrm{d}}{\mathrm{d}R}\left(\frac{a_CZ^2R_0}{e}R^{-1}\right)\right|=\left|\frac{a_CZ^2R_0}{e}R^{-2}\right|=\frac{a_CZ^2R_0}{|e|}R_0^{-2}A^{-2/3}=\frac{a_CZ^2}{|e|R_0}A^{-2/3}\end{gathered} \tag{11.4.440}$$

If the Coulomb repulsion prevails, the fission prevails and we then have:

$$F_C(R)>F_S(R) \tag{11.4.441}$$

Therefore:

$$\frac{a_CZ^2}{|e|R_0}A^{-2/3}>\frac{2a_S}{|e|R_0}A^{1/3} \tag{11.4.442}$$

After simplification, it remains:

$$a_CZ^2A^{-2/3}>2a_SA^{1/3} \tag{11.4.443}$$

Therefore:

$$\frac{Z^2}{A}>\frac{2a_S}{a_C}\cong\frac{2\cdot 18.34}{0.71}\cong 52 \tag{11.4.444}$$

Since this ratio for ${}^{236}_{92}\mathrm{U}$ is close to 36 and therefore less than 52, this approach naively explains why there can be no symmetrical fission (as experience confirms it!).

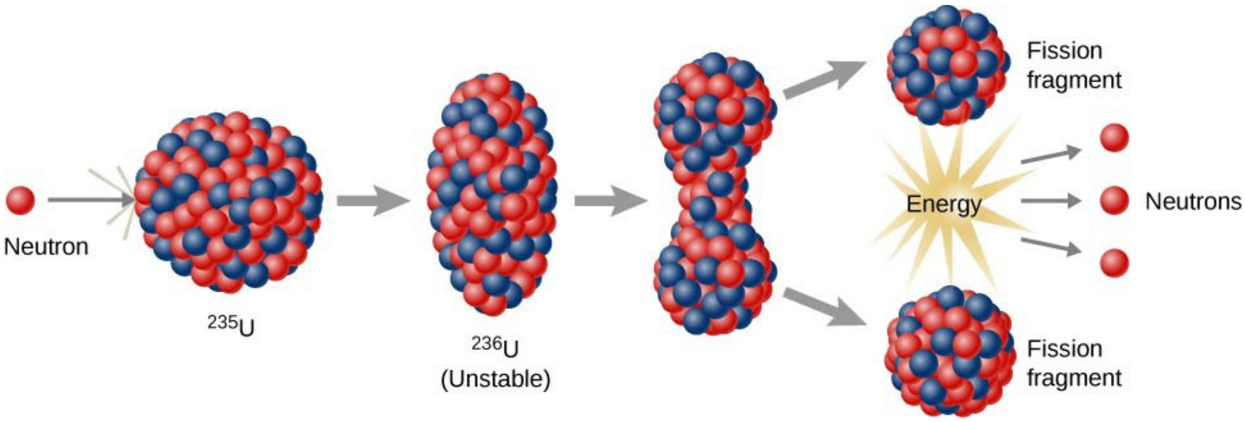

Figure 11.143: **Liquid drop model of Uranium 235 nuclear fission (source: OpenStax)**

We will conclude this section with a brief summary of the assumptions of each of the nuclear models we have discussed and what each can tell us about nuclear structure:

- **Liquid-drop model**: This model assumes that all nuclei have similar mass densities, with binding energies approximately proportional to their masses, just as in a classical charged liquid drop. The model leads to the SEMF (semi-empirical mass formula), which gives a good description of the average masses and binding energies. It is largely classical, with some quantum mechanical terms (the asymmetry and pairing terms) inserted in an ad hoc way. Input from experiment is needed to determine the coefficients of the SEMF.
- **Fermi gas model**: The assumption here is that nucleons move independently in a net nuclear potential. The model uses quantum statistics of a Fermi gas to predict the depth of the potential and the asymmetry term of the SEMF.
- **Shell model**: This is a fully quantum mechanical model that solves the Schrödinger equation with a specific spherical nuclear potential. It makes the same assumptions as the Fermi gas model about the potential, but with the addition of a strong spin–orbit term. It is able to successfully predict nuclear magic numbers, spins and parities of ground-state nuclei and the pairing term of the SEMF. It is less successful in predicting magnetic moments.
- **Collective model**: This is also a fully quantum mechanical model, but in this case the potential is allowed to undergo deformations from the strictly spherical form used in the shell model. The result is that the model can predict magnetic dipole and electric quadrupole magnetic moments with some success. Additional modes of excitation, both vibrational and rotational, are possible and are generally confirmed by experiment.

11.5. Quantum Field Theory

BEFORE the formulation of quantum physics, particles and fields were considered separate but linked. The particles have certain intrinsic characteristics (such as mass and electric charge) and produce fields (electromagnetic and gravitational). Each force field emanating from the particles and fills the space around them. The fields can store and transport energy; they are, in this sense, the real continuum that bind particles and communicate the interactions between them. It was considered that the particles were composed of matter and energy fields were compounds. The concept of force field was the alternative of the 119th century (holocene calendar) old and mysterious action at a distance. Particles that don't react to any force field are unobservable and physically are no sense. Similarly, force fields that act on no particles are also meaningless. The concepts of particles and fields thus have a sense only when they are connected.

The notion of field began to be fundamentally changed with the introduction by Albert Einstein of the concept of "photon". Under this new concept, the electromagnetic field has no energy distributed in a continuous manner in space. The photon is the "quantum of the electromagnetic field". It carries the energy and momentum of the field. The electromagnetic interaction between two charged particles and the transfer of energy and the amount of movement of a particle to another must therefore take place by the exchange of electromagnetic quanta of energy: the photons. The theory of such interactions (between charged particles), named "quantum electrodynamics" (QED), was the first successful application of these ideas (it allows to prove the fine structure of the Sommerfeld model, to explain the spin of the electron, etc.) and it is to it that we will look here.

Keep in mind however that in Quantum Field theory (QFT), there are fields for all types of subatomic particles, including quarks and electrons. The quark field describes the behavior of quarks, and the electron field describes the behavior of electrons. These fields are described by mathematical equations and can be used to make predictions about the behavior of these particles in different situations as we will see it. Mathematically, the quantum fields themselves are made up of quantum oscillators, an infinity-of-infinities of them as we will also see it! These oscillators are little gadgets, everywhere, that spew out and consume quanta, the building blocks of our world. In the early 121st century (holocene calendar) we don't know whether they exist (whatever "existing" means) and professional physicists don't really care as Science is just a tool based on a methodology. The point of physics is not to describe how the Universe actually is, but rather to say what it is like. The quantum oscillators can be seen as "energy reservoirs" and as we already know with everything what we have study so far: we don't know what is energy actually but we just know that in closed and human size systems (to a given order of magnitude) it is conserved!

The study of Quantum Field Theory is important as the Standard Model has in this early 121st century (according to holocene calendar) 17 quantum fields: 12 matter fields, 4 force fields, and the Higgs field as depicted in the illustration below (the gravitational field is not yet considered as a quantum field, until a viable theory of quantum gravity is established):

Figure 11.146: **Subparticles Standard Model (source: Wikipedia)**

In this section, we do not wish to make a complete course of Quantum Field Theory because for reminder, this entire textbook is only intended to give the basics of what an engineer must know in the early 121st century (holocene calendar) and incidentally the author to have fun studying subjects that he had not seen during his school curriculum. As such, the interested reader to deepen over this matter may be read to best textbook we've ever had hands so far (detailed, simple and pedagogical developments with many practical cases) on the subject which is [141].

Remark

Quantum Field Theory is the application of Quantum Mechanics to fields. It provides a framework widely used in Particle Physics and Condensed Matter Physics. The basics of Quantum Field Theory to which we will limit our study were developed between 11935 (holocene calendar) and 11955 (holocene calendar), mainly by Paul Dirac, Wolfgang Pauli, Sin-Itiro Tomonaga, Julian Schwinger, Richard Feynman and Freeman Dyson.

Before we launch into the calculations (see below), let us show that the approach suggested above, can be considerate with a simple formalism (pedagogical).

Readers should however remember that simple approaches require sometimes erroneous mental constructions (overly simplistic) compared to reality, but which meet the objective: to have a more or less understandable and intuitive model.

Consider at this purpose the figure below (representation of the elastic collision of two electrons):

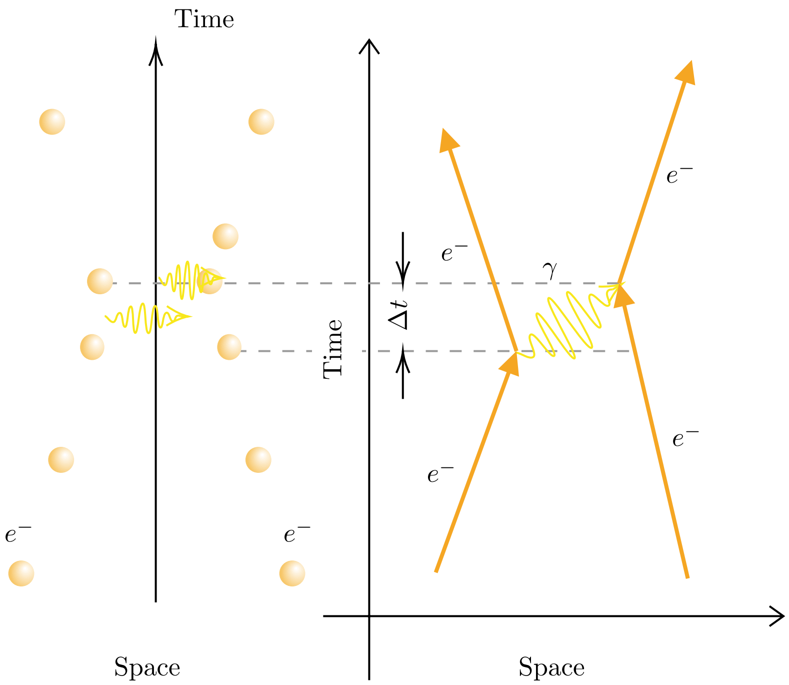

Figure 11.147: Example of pseudo Feynman-diagram

This figure is named, and wrongly (!), in many educational textbooks "Feynman diagram" (in reality it is only a diagram that looks like a little bit because the real Feynman diagrams are intended to calculate Wick products in a perturbation series).

Let us suppose that two electrons which are represented, initially move at the same speed. They approach first and then move away from each other along a straight line in space that is projected on the time axis, in the direction of increasing time. The left electron emits a photon (the wavy line), and for a time Δt, there are two electron and a photon. The electron on the right then absorbs the photon and the interaction is temporarily ended; other photons will eventually go back and forth between the electrons. The average force is proportional to the transfer rate of the amount of movement due to the exchange of photons. The probability of the emission or absorption of photons by a particle is connected to its electric charge. The force must be proportional to the product of the charges in interaction (according to Coulomb's law). Think of the repulsive force between two astronauts floating in space and sharing a ball in one direction and then the other (this is an educational approach to the problem but does not apply for example to the attraction between two particles of opposite charges!). However, the opposite phenomenon of attraction cannot be viewed in this way but only in formal mathematical form.

💣Caution!!!! At the quantum level, it is more accurate rigorously to speak about "interactions" rather than "forces". This is because the classical notion of a force as a continuous and deterministic influence that acts on an object over a distance breaks down at the quantum level. The concept of an interaction in Quantum Field Theory is more general than the classical notion of a force as an interaction can encompass both attractive and repulsive effects, and it can be mediated by a variety of particles, including photons, gluons, and W and Z bosons. In summary, while the classical notion of a force can still be useful in certain contexts (especially for pedagogical reason for undergraduate students), it is more accurate to speak about "interactions" at the quantum level, which are described by quantum fields and the exchange of virtual particles.

The collision shown in the figure above is elastic; the energy of each electron is unchanged in the collision. Despite this, for a time Δt, the system contains an additional energy $h\nu$ corresponding to the photon. Meanwhile this time Δt, conservation of energy is apparently non respected! Can we tolerate this situation? The answer given by modern physics, is: Yes! But it can never be observed (...). In other words, because there is always some uncertainty ΔE on the measured value of the energy of a system. The Heisenberg's uncertainty principle involving (see the simplified proof in the section of Wave Quantum Physics page 4704) that:

$$\Delta t \Delta E \cong \hbar \qquad (11.5.1)$$

A violation of the energy conservation law until a given amount ΔE will be hidden by uncertainty on energy provided that the time available to make the observation is sufficiently small as having for upper value:

$$\Delta t \cong \frac{\hbar}{\Delta E} \qquad (11.5.2)$$

obviously a value less than Δt also satisfies the condition. We can therefore write:

$$\Delta t \geq \frac{\hbar}{\Delta E} \qquad (11.5.3)$$

The uncertainty on the energy exceeds the energy of a photon $h\nu$ if the photon exists for a shorter time than:

$$\Delta t = \frac{\hbar}{h\nu} = \frac{1}{4\pi\nu} \qquad (11.5.4)$$

The photon can then be observed on a maximum distance of:

$$\boxed{R_\nu = c\Delta t = \frac{c}{4\pi\nu}} \qquad (11.5.5)$$

and as the frequency ν can be arbitrarily small, the scope of the transmitted force by the photon without mass is unlimited. It may seem in this relation that the scope is limited to a free photon. But this would be forgetting (see section Wave Quantum Physics page 4785) that a free photon does not exist, because it would have a totally unknown frequency. Therefore the interaction distance would be also undetermined.

These exchange of quanta, that are unobservable, are named "virtual photons". Since photons are not electrically charged, we also say that the interaction is made by "neutral current".

Remark

The term "virtual particle" is an endlessly confusing and confused subject for the layperson, and even for the non-expert scientist!!! A particle is a nice, regular ripple in a field, one that can travel smoothly and effortlessly through space, like a clear tone of a bell moving through the air. A "virtual particle", generally, is a disturbance in a field that will never be found on its own, but instead is something that is caused by the presence of other particles, often of other fields. A particle is a nice, regular ripple in a field, one that can travel smoothly and effortlessly through space, like a clear tone of a bell moving through the air. Physicists often say, and laypersons' books repeat, that the two electrons exchange virtual photons. But those are just words, and they lead to many confusions if you start imagining this word "exchange" as meaning that the electrons are tossing photons back and forth as two children might toss a ball.

A much more satisfactory approach is that of using mass as energy term:

$$\Delta t \leq \frac{\hbar}{m_0 c^2} \qquad (11.5.6)$$

Thanks to this relation, it is possible to know the time during which a massive virtual particle can travel a distance that would be:

$$\boxed{R_m = c\Delta t = \frac{\hbar}{m_0 c}} \qquad (11.5.7)$$

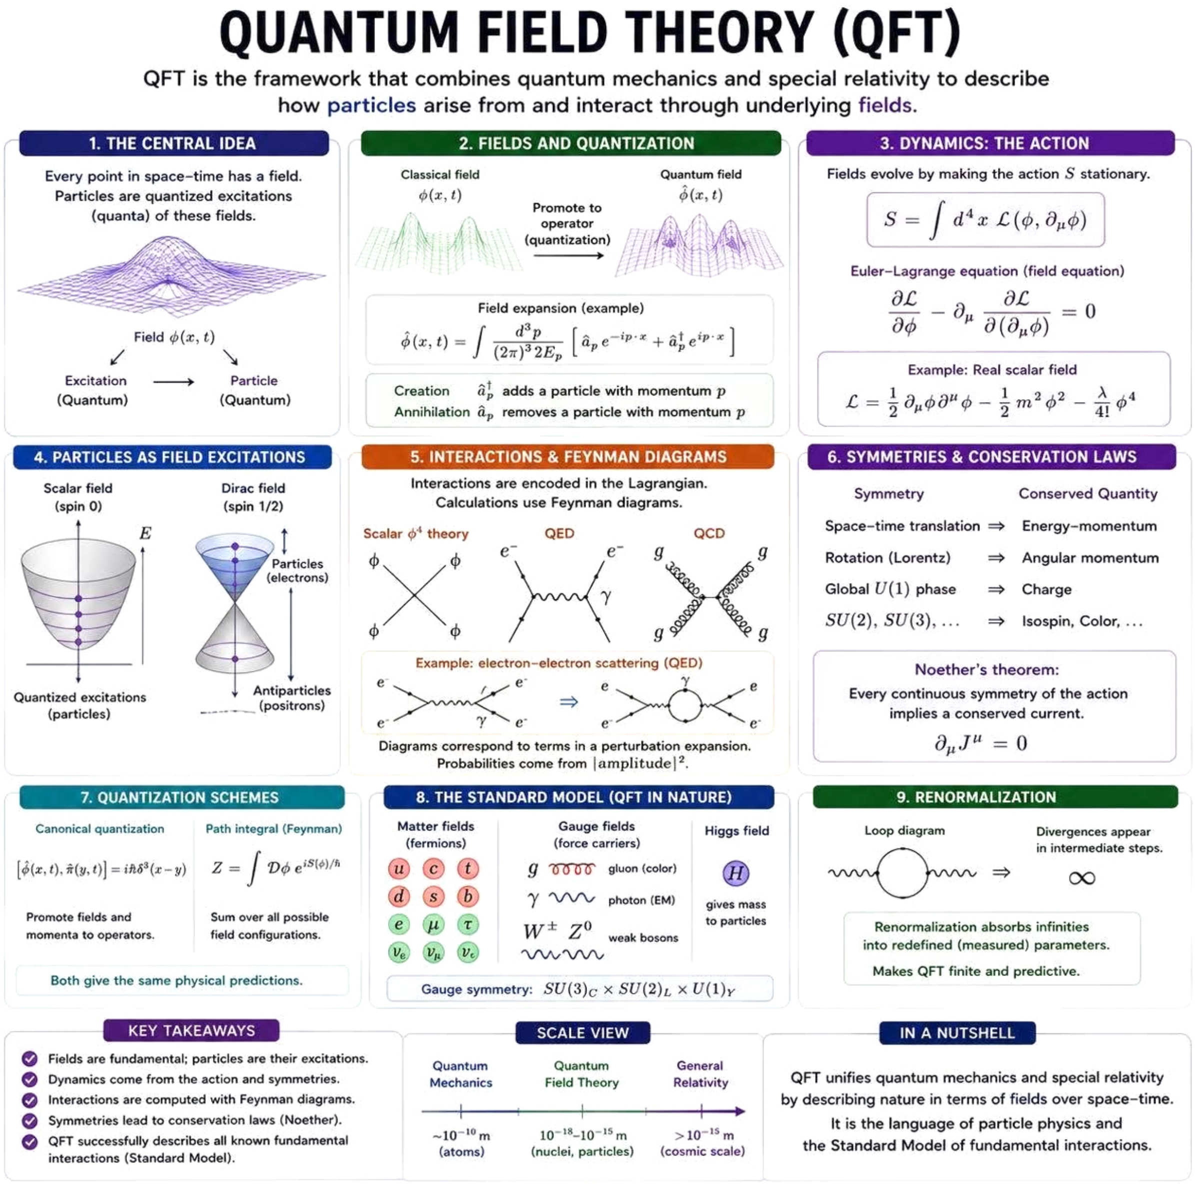
We will see later how to approximately determine the mass of virtual particles that mediate in the nuclear forces which will allow us to estimate the duration of interactions as being of the order of 10^{-24} [s].

In the late 11920s (holocene calendar), it became clear that we could consider each known particle (proton, electron, etc.) as the quantum of a specific field. In this vision, there is an electron field, a proton field, and so on as will be proven below (the Universe would be a set of unified field). Any object is in reality a set of manifestations of observables of field quantas.

Furthermore, we saw that the writing of wave equations for relativistic particles (Dirac equation and Klein-Gordon equation proven in the section of Relativistic Quantum Physics) brings intractable problems in a classical point of view, including negative energies. In fact, this approach is not justified, because according to Einstein equation mass and energy are equivalent, and if we add to that the energy-time Heisenberg's uncertainty principle we find that an infinite number of particles can be created or annihilated, hence the need for a model to take into account not only the properties of a single particle, but of a set of particles, both real and virtual!

Remark

When Fermi formulated his theory of weak interactions in 11932 (holocene calendar), he used the same principles those of quantum electrodynamics (this is one reason why QED is named the "jewel of physics" - the Standard Model is also based on this theory). Two years later, the Japanese physicist Hideki Yukawa proposed that the weak interaction was due to the exchange of a massive virtual boson.



QUANTUM FIELD THEORY (QFT)

QFT is the framework that combines quantum mechanics and special relativity to describe how particles arise from and interact through underlying fields.

1. THE CENTRAL IDEA

Every point in space-time has a field. Particles are quantized excitations (quanta) of these fields.

Field $\phi(x,t)$
Excitation (Quantum)
Particle (Quantum)

2. FIELDS AND QUANTIZATION

Classical field $\phi(x,t)$
Promote to operator (quantization)
Quantum field $\hat{\phi}(x,t)$

Field expansion (example)

$$\hat{\phi}(x,t)=\int\frac{d^3p}{(2\pi)^3 2E_p}\left[\hat{a}_p e^{-ip\cdot x}+\hat{a}_p^\dagger e^{ip\cdot x}\right]$$

Creation $\hat{a}_p^\dagger$ adds a particle with momentum p

Annihilation $\hat{a}_p$ removes a particle with momentum p

3. DYNAMICS: THE ACTION

Fields evolve by making the action S stationary.

$$S=\int d^4x\,\mathcal{L}(\phi,\partial_\mu\phi)$$

Euler-Lagrange equation (field equation)

$$\frac{\partial\mathcal{L}}{\partial\phi}-\partial_\mu\frac{\partial\mathcal{L}}{\partial(\partial_\mu\phi)}=0$$

Example: Real scalar field

$$\mathcal{L}=\frac{1}{2}\partial_\mu\phi\partial^\mu\phi-\frac{1}{2}m^2\phi^2-\frac{\lambda}{4!}\phi^4$$

4. PARTICLES AS FIELD EXCITATIONS

Scalar field (spin 0)
Dirac field (spin 1/2)
E
Particles (electrons)
Quantized excitations (particles)
Antiparticles (positrons)

5. INTERACTIONS & FEYNMAN DIAGRAMS

Interactions are encoded in the Lagrangian. Calculations use Feynman diagrams.

Scalar ϕ^4 theory
ϕ
ϕ
ϕ
ϕ
QED
e^-
e^-
γ
QCD
g
g
g
g
Example: electron-electron scattering (QED)
e^-
e^-
γ
e^-
e^-
$\Rightarrow$
e
γ
e
e^-
e^-

Diagrams correspond to terms in a perturbation expansion. Probabilities come from $|\text{amplitude}|^2$.

6. SYMMETRIES & CONSERVATION LAWS

Symmetry		Conserved Quantity
Space-time translation	⇒	Energy-momentum
Rotation (Lorentz)	⇒	Angular momentum
Global $U(1)$ phase	⇒	Charge
$SU(2)$, $SU(3)$, …	⇒	Isospin, Color, …

Noether's theorem:

Every continuous symmetry of the action implies a conserved current.

$$\partial_\mu J^\mu=0$$

7. QUANTIZATION SCHEMES

Canonical quantization	Path integral (Feynman)
$[\hat{\phi}(x,t),\hat{\pi}(y,t)]=i\hbar\delta^3(x-y)$	$Z=\int\mathcal{D}\phi\,e^{iS(\phi)/\hbar}$
Promote fields and momenta to operators.	Sum over all possible field configurations.

Both give the same physical predictions.

8. THE STANDARD MODEL (QFT IN NATURE)

Matter fields (fermions)

u c t

d s b

e μ τ

ν_e ν_μ ν_τ

Gauge fields (force carriers)

g gluon (color)

γ photon (EM)

$W^\pm$ Z^0 weak bosons

Higgs field

H gives mass to particles

Gauge symmetry: $SU(3)_C\times SU(2)_L\times U(1)_Y$

9. RENORMALIZATION

Loop diagram
$\Rightarrow$
∞

Divergences appear in intermediate steps.

Renormalization absorbs infinities into redefined (measured) parameters.

Makes QFT finite and predictive.

KEY TAKEAWAYS

- ✓ Fields are fundamental; particles are their excitations.
- ✓ Dynamics come from the action and symmetries.
- ✓ Interactions are computed with Feynman diagrams.
- ✓ Symmetries lead to conservation laws (Noether).
- ✓ QFT successfully describes all known fundamental interactions (Standard Model).

SCALE VIEW

Quantum Mechanics	Quantum Field Theory	General Relativity
$\sim 10^{-10}$ m (atoms)	10^{-18}–10^{-15} m (nuclei, particles)	$>10^{-15}$ m (cosmic scale)

IN A NUTSHELL

QFT unifies quantum mechanics and special relativity by describing nature in terms of fields over space-time.

It is the language of particle physics and the Standard Model of fundamental interactions.

11.5.1 Yukawa potential

The best way to argue the example of quantum remains the "proof" of the Coulomb's law (and also of Newton's Law) from the results we have achieved in Wave Quantum Physics (we own these developments to the physicist Hideki Yukawa).

A simplified version of this proof as we like them in this textbook is to first remember the free Klein-Gordon equation (see section Wave Quantum Physics page 4921):

$$\hbar^2\frac{\partial^2\Psi}{\partial t^2}=\hbar^2c^2\Delta\Psi-m_0^2c^4\Psi \tag{11.5.8}$$

this equation describes the amplitude dynamics of presence of a particle without spin in time in a given potential.

Let us consider a static component of Ψ (time-independent) with spherical symmetry:

$$\Psi = U(r) \tag{11.5.9}$$

The Klein-Gordon equation is then reduced to:

$$\hbar^2 c^2 \Delta U(r) - m_0 c^4 U(r) = 0 \tag{11.5.10}$$

If we divide on the both side of the equality by $\hbar^2 c^2$ we get obviously:

$$\Delta U(r) - \hbar^{-2} m_0 c^2 U(r) = 0 \tag{11.5.11}$$

Let us recall (see section Vector Calculus page 1899) the notation of the Laplacian of a scalar field:

$$\vec{\nabla}^2 = \Delta \tag{11.5.12}$$

and also its expression in spherical coordinates where $r = 0$ is identified to the source of the field (see section Vector Calculus page 1903):

$$\vec{\nabla}^2 f = \frac{\partial^2 f}{\partial r^2} + 2\frac{1}{r}\frac{\partial f}{\partial r} + \frac{1}{r^2}\frac{\partial^2 f}{\partial \theta^2} + \frac{\cot(\phi)}{r^2}\frac{\partial f}{\partial \theta} + \frac{1}{r^2 \sin^2(\theta)}\frac{\partial^2 f}{\partial \phi^2} \tag{11.5.13}$$

As the field $U(r)$ has a spherical symmetry (depending on r only) the Laplacian is reduced to:

$$\vec{\nabla}^2 f = \frac{\partial^2}{\partial r^2} + 2\frac{1}{r}\frac{\partial}{\partial r} = \frac{1}{r^2}\frac{\partial}{\partial r}\left(r^2 \frac{\partial}{\partial r}\right) \tag{11.5.14}$$

So the equation of the field U (r) is written:

$$\frac{1}{r^2}\frac{\partial}{\partial r}\left(r^2 \frac{\partial}{\partial r} U(r)\right) - \hbar^{-2} m_0^2 c^2 U(r) = 0 \tag{11.5.15}$$

This differential equation has for solution (we guess easily enough that the exponential is a possible solution):

$$U(r) = \frac{C}{r} e^{-r(\hbar^{-1} m_0 c)} \tag{11.5.16}$$

where C is an integration constant.

In the context of the use of natural units (which is most common at this level in the scientific literature) this potential is written:

$$U(r) = \frac{C}{r} e^{-r m_0} \tag{11.5.17}$$

and is named "Yukawa potential".

The reader will notice that apart from the distance r, the other variable in the exponential is the mass (the other terms are universal constants).

Consequence: the Yukawa potential has the aspect of a "scalar field" in the case where the mass is zero (see example below) and at the same time has the aspect of a "mass field" in the case where the mass is not zero!

This leads us to the following hypothesis: if it is the electric field that holds charged particles in the atom between them (see the treatment of non-mass fields below), it is the mass field which keeps the uncharged particles together in the atom.

In other words, if particles interact via a mass field of mass m_0 (instead of interacting with massless photons), their mutual strength will decrease exponentially (which is very fast).

The above relation is often denoted:

$$U(r)=g\frac{e^{-rm_0}}{r} \tag{11.5.18}$$

Where g is a constant that represent the strength of pion field similarly to electric charge q representing the strength of electromagnetic field. The above expression represents the exponential form of scalar meson potential or one pion exchange potential.

Yukawa's approach allows a new point of view to the interpretation of nuclear phenomena, but it is however too naive to adequately explain the strong interactions in general.

11.5.1.1 Mass fields

The physicist Hideki Yukawa therefore proposed in 11935 (holocene calendar) that nuclear power was own its very short range by the fact that it is transmitted by massive particles (more the mass of exchanged quanta is big, the greater the range of the interaction is reduced) described by the mass field above.

Remark

In the historical context of the time, these hypothetical particles were "mesons". But we will see that this assumption did not hold up very long.

Let's take a closer look to this. Let us write the Yukawa potential as follows:

$$U(r)=\frac{C}{r}e^{-r/R} \tag{11.5.19}$$

with:

$$\boxed{R=\frac{\hbar}{m_0 c}} \tag{11.5.20}$$

This notation is not innocent, because as we will see it in detail later, when $R\rightarrow+\infty$ (the case of electromagnetic and gravitational interaction) then $m_0\rightarrow 0$ and then we fall back on the fundamental law of electrodynamics or of gravitation where the particle interaction is respectively the photon (null mass) and the hypothesized graviton.

Thus, assuming that the radius of the strong nuclear force (cohesion of nucleons between them) is around $R\cong 1\cdot 10^{-15}$ [m] and that of the weak nuclear interaction (which should be the cause of the beta disintegration as we already mentioned in the section of Nuclear Physics) around $R\cong 1\cdot 10^{-18}$ [m], we get the binding interaction energies and their approximate weight immediately:

- For the "strong interaction":

$$\begin{aligned}E=m_0c^2=\frac{\hbar c}{R}\cong 3.15\cdot 10^{-12}\,[\text{J}]\cong 196\,[\text{MeV}]\\ m_0=\frac{\hbar}{cR}\cong 3.5\cdot 10^{-28}\,[\text{kg}]\cong 386 m_e\cong\frac{1}{5}m_p\end{aligned} \tag{11.5.21}$$

  that is to say approximately 386 times the mass of the electron (m_e) and $1/5$ the mass of the proton (m_p).

  Two years after this prediction of Hideki Yukawa, physicists discovered a particle corresponding to this mass: the meson μ^-. It was later that it was not good the good particle but a particle of the same type as the electron particle, that is to say a lepton and therefore a fermion[41] (so it can not be a messenger particle!!). Furthermore, the experiences of diffusion and collisions with protons, deuterons, etc. at energies higher and higher showed that there was a change in the intensity and shape of the strong interaction incompatible with the hypothesis of a single meson. Furthermore, the hadronic resonances showed that there was meson excited states which is hard to imagine for particles considered fundamental in analogy with the photon!!

---

[41] Go see the table of fundamental particles in the section Elementary Particle Physics at page 5200 to see how physicists classify elementary particles of the Standard Model

The particles detected in the laboratory and that seemed to be the best candidates at that time (since there were several ...) for the strong nuclear force were "pions" (or "pi mesons") which are know under three forms (at least at the time we write these lines):

$$\pi^+,\pi^-,\pi^0$$

and which are almost 270 times more massive than the electron. So this mass difference clearly indicates that the model of Yukawa is not entirely accurate.

Before the discovery of quarks (which mesons are made of), the pi mesons (pions) were therefore considered to be the vectors of the strong interaction (today we know that in fact these vectors are gluons).

- For the "weak interaction":

$$\begin{aligned}E&=m_0c^2=\frac{\hbar c}{R}=3.15\cdot 10^{-8}\,[\text{J}]\cong 196\,[\text{GeV}]\\ m_0&=\frac{\hbar}{cR}\cong 3.5\cdot 10^{-25}\,[\text{kg}]\end{aligned}\tag{11.5.22}$$

  It is therefore a colossal mass, a hundred times the mass of the proton! The vectors of interaction have been candidates that were identified in 11983 (holocene calendar) in the CERN accelerator. These carrier particles of the weak nuclear force are named "intermediate bosons" and denoted by W^+, W^-, Z^0.

These observations led the hypothesis that Yukawa's theory was not a fundamental theory enough even if it explain quite well some properties...

11.5.1.2 Non-mass fields

Let us now imagine a static scalar field with a spherical symmetric which the photon (particle without spin) is the hypothetical quantum exchange. As the photon's mass is zero, the expression $U(r)$ is reduced to:

$$U(r)=\frac{C}{r}\tag{11.5.23}$$

If we interpret $U(r)$ as the electrostatic potential source of a quantity $Q=nq$ of elementary electric charges q, then the constant C in our metric is:

$$C=\frac{Q}{4\pi\varepsilon}\tag{11.5.24}$$

Such that:

$$U(r)=\frac{1}{4\pi\varepsilon}\frac{Q}{r}\tag{11.5.25}$$

As we have:

$$U(r) = -\int_{\Lambda} E\mathrm{d}r \tag{11.5.26}$$

We get:

$$\frac{\mathrm{d}U(r)}{\mathrm{d}r} = -E = -\frac{1}{4\pi\varepsilon}\frac{Q}{r^2} \tag{11.5.27}$$

Which give us:

$$E = \frac{1}{4\pi\varepsilon}\frac{Q}{r^2} \tag{11.5.28}$$

We can conclude that if a particle is in a potential field with spherical symmetry $U(r)$, whose photon is assumed to be initially the interacting quantum, then we are dealing with an electrostatic field whose expression is identical to the Coulomb law (this valid once again in a big way the Wave Quantum Physics theory).

Remark

Hubert Reeves and his colleagues astrophysicists proved that at the time of the genesis of the Universe, the smallest deviance in coupling constants would have caused the instability of nucleons and would have condemned cosmic evolution.

The photon is therefore indeed the quantum interaction of the electric field with spherical symmetry (when the electric charges have a relativistic speed the electric field is not spherical anymore, and the equations become a bit more complicated - see the section of Special Relativity for some details about this) and we should not talk of electric charges but of "transparency" to photons. Indeed, the neutron being globally neutral it should not interact with the electric field, but as it is composed of charged particles (quarks) experiments show an influence in the presence of an electromagnetic field (which photon is the quantum interaction). That said, applying the same reasoning, we can still find the Newton's gravitational potential:

$$a = G\frac{M}{r^2} \tag{11.5.29}$$

This would imply that the quantum interaction of the gravitational field is massless (at least in the case of small masses as we know the Newton's potential is only an approximation of General Relativity in the case of small masses). Since the gravitational field does not seem to interact with the presence of a magnetic or electrostatic field, this leads us to speculate that the quantum of interaction is not the photon but another hypothesized particle that we name the "graviton".

11.5.2 Euler-Lagrange equation for Fields

How field theory was introduced from the elementary particles by Dirac is known for historical reasons under the name of "second quantization".

It may be useful to identify a possible source of confusion: the fields are not related to the wave-particle duality. What we mean by "field" is a concept that allows the creation or annihilation of particles at any point in space as we will discussed it in the mathematical developments below.

Recall that we have defined in the section of Wave Quantum Physics during the study of the Schrödinger's evolution equation the Heisenberg's operator necessary for the de Broglie normalization condition:

$$X(t)=e^{\frac{\mathrm{i}t}{\hbar}H}Xe^{-\frac{\mathrm{i}t}{\hbar}H}\tag{11.5.30}$$

Differentiating this operator with respect to time, we trivially have trivially (once known the notation seen in the section of Wave Quantum Physics):

$$\dot{X}(t)=\frac{\mathrm{i}H}{\hbar}e^{\frac{\mathrm{i}t}{\hbar}H}Xe^{-\frac{\mathrm{i}t}{\hbar}H}-\frac{\mathrm{i}H}{\hbar}e^{\frac{\mathrm{i}t}{\hbar}H}Xe^{-\frac{\mathrm{i}t}{\hbar}H}=-\frac{\mathrm{i}}{\hbar}[X(t),H]\tag{11.5.31}$$

where for recall, the commutator of two operators is given (as we have already seen it in our study of adjoint and Hermitian operators in the section of Wave Quantum Physics) by definition:

$$[\alpha,\beta]=\alpha\beta-\beta\alpha\tag{11.5.32}$$

This is the Hamiltonian H which appears first in the previous prior previous relation.

Now, as we know, we can substitute to $\dot{X}(t)$ observable that are also well known to us such that we get in the case of a constant Hamiltonian:

$$\boxed{\begin{aligned}\dot{q}(t)&=\frac{\mathrm{i}}{\hbar}[q(t),H]\\ \dot{p}(t)&=\frac{\mathrm{i}}{\hbar}[p(t),H]\end{aligned}}\tag{11.5.33}$$

But we can just as easily substitute a time-dependent Hamiltonian $H(t)$ such that:

$$\dot{X}(t)=-\frac{\mathrm{i}}{\hbar}[X(t),H]+e^{\frac{\mathrm{i}t}{\hbar}H}\frac{\partial X}{\partial t}e^{-\frac{\mathrm{i}t}{\hbar}H}\tag{11.5.34}$$

For example, as we know (see section Wave Quantum Physics page 4695), X can be replaced by the operators $q(t)\rightarrow\hat{q}(t)$ or $p(t)\rightarrow-\mathrm{i}\hbar\partial_k$. Then in this special cases we see that we can simplify the previous relation by:

$$\boxed{\dot{X}(t)=-\frac{\mathrm{i}}{\hbar}[X(t),H]+\partial_t X}\tag{11.5.35}$$

This is named "Heisenberg equation of motion".

What is interesting in the two relations $\dot{q},\dot{p}$ obtained previously, is the way in which is realized the connection between quantum physics and classical mechanics. Indeed, we proved in the section of Analytical Mechanics the following relations are will always be valid whatever the subject area:

$$\begin{aligned}\dot{q}(t)&=\frac{\partial H(t)}{\partial p(t)}\\ \dot{p}(t)&=-\frac{\partial H}{\partial q(t)}\end{aligned} \tag{11.5.36}$$

and also that:

$$p=\frac{\partial L}{\partial \dot{q}} \tag{11.5.37}$$

and assuming the generalization to several degrees of freedom as intuitive:

$$H=\sum p_n\dot{q}_n-L \tag{11.5.38}$$

The generalization to several degrees of freedom is immediate and gives us all the following relations (we simplify the notation by omitting the explicit time dependence):

$$p_n=\frac{\partial L}{\partial \dot{q}_n} \quad \text{and} \quad H=\sum p_n\dot{q}_n-L \tag{11.5.39}$$

and also:

$$\begin{cases}\dot{q}_n=\dfrac{\partial H}{\partial p_n}\\ \dot{p}_n=-\dfrac{\partial H}{\partial q_n}\end{cases} \quad \text{and} \quad \begin{cases}\dot{q}_n=-\dfrac{\mathrm{i}}{\hbar}[q_n,H]\\ \dot{p}_n=-\dfrac{\mathrm{i}}{\hbar}[p_n,H]\end{cases} \tag{11.5.40}$$

We still need two other important relations that we will immediately determined. First, according to the definitions of the commutators, we already prove in the section of Analytical Mechanics:

$$[q,q]=[p,p]=0 \tag{11.5.41}$$

By cons, it is a little more subtle to prove the value of $[q,p]$ (we joke...). Recall that we had prove in our study functional linear operators (we restrict ourselves to the case of the x here):

$$p_x=\frac{\hbar}{\mathrm{i}}\frac{\partial}{\partial x} \tag{11.5.42}$$

and that q represents a generalized coordinate (x for example ...). So we have (results already proven in the section of Wave Quantum Physics):

$$[q,p]=\left[x,\frac{\hbar}{\mathrm{i}}\frac{\partial}{\partial x}\right]=x\frac{\hbar}{\mathrm{i}}\frac{\partial}{\partial x}-\frac{\hbar}{\mathrm{i}}\frac{\partial}{\partial x}x=0-\frac{\hbar}{\mathrm{i}}=\mathrm{i}\hbar \tag{11.5.43}$$

The last two relations can be generalized to all necessary components such as:

$$\boxed{[q_i,q_j]=[p_i,p_j]=0 \quad [q_i,p_j]=\mathrm{i}\hbar\delta_{ij}} \tag{11.5.44}$$

with for recall (see section Tensor Calculus page 2044):

$$\delta_{ij}=\delta^{ij}=\delta_i^j=\begin{cases}1 & \text{if } i=j\\ 0 & \text{if } i\neq j\end{cases} \tag{11.5.45}$$

which is the Kronecker symbol.

To arrive finally to Quantum Field Theory, we still need to generalize to a continues infinite number of degrees of freedom. Even the simplest of fields is characterized, at a time t, by an infinity of continuous quantities:

$$\Phi(x,y,z,t)=\Phi(\vec{x},t)=\Phi^A \tag{11.5.46}$$

for any $\vec{x}$. We could then imagine to represent the function Φ by its values $\Phi(\vec{x},t)$ in a discrete set of points $\vec{x}_i$ that we will ultimately make infinitely dense (beware of the fact that we use the concept of density!). We can also work, to begin, not in all space, but in a finite volume that we will eventually make very large. By doing so, we can find how to generalize the canonical formalism and the quantification process. At the formal level, notwithstanding subtle issues of convergence (see the mathematical parts of this textbook), the generalization to continuous systems is mainly to replace the quantities with index i by integrals of the arguments $\vec{x}$, and the deltas of Kronecker by the delta of Dirac (on space-time):

$$\delta^4\left((x_1,y_1,z_1,t)-(x_2,y_2,z_2,t)\right)=\delta^4\left((A)-(B)\right)=\delta^4(\vec{x}-\vec{y})=\delta^4_{AB} \tag{11.5.47}$$

Considering then the variational principle as we have studied it in the section of Analytical Mechanics:

$$S(q,\dot{q})=\int\limits_{t_A}^{t_B} L(q,\dot{q})\mathrm{d}t \tag{11.5.48}$$

and the principle of least action requiring us to have:

$$\delta S=\delta\int\limits_{t_A}^{t_B} L\mathrm{d}t=\int\limits_{t_A}^{t_B}\delta L\mathrm{d}t=0 \tag{11.5.49}$$

where the Lagrangian will be now a function of the field $\Phi(\vec{x},t)$ and of derivative with respect to $\phi(\vec{x},t)$ (since there is no concept of momentum for a field!).

If we divide the above equation by $\delta q(t)=\delta q\neq 0$ we get:

$$\frac{\delta S(q,\dot{q})}{\delta q}=0 \tag{11.5.50}$$

what gives us the right to write:

$$\delta S(q,\dot{q})=\int\frac{\delta S(q,\dot{q})}{\delta q}\delta q\mathrm{d}t=\int\delta q\mathrm{d}t=0 \tag{11.5.51}$$

and imposing an analogy with the concept of field:

$$\delta S(q,\dot{q})=\int\frac{\delta S(q,\dot{q})}{\delta q}\delta q\mathrm{d}t=\int\frac{\delta S(\Phi^A,\dot{\Phi}^A)}{\delta\Phi^A}\delta\Phi^A\mathrm{d}x^4 \tag{11.5.52}$$

where $x := (\vec{x}, t)$ and $\mathrm{d}x^4 = \mathrm{d}x_1 \mathrm{d}x_2 \mathrm{d}x_3 \mathrm{d}x_t$.

Finally, since all the following terms are equal to zero, they are equal (we introduce the Euler-Lagrange equation proved in the section of Analytical Mechanics):

$$\delta S(q,\dot{q}) = \frac{\delta S(q,\dot{q})}{\delta q(t)} = \frac{\partial L}{\partial q_i(t)} - \frac{\mathrm{d}}{\mathrm{d}t}\frac{\partial L}{\partial \dot{q}_i(t)} = 0 \tag{11.5.53}$$

in analogy with the field Φ^A we get (thus it is an intuitive approach with the physicist way of life...):

$$\frac{\delta S(\Phi^A, \dot{\Phi}^A)}{\delta \Phi^A} = \frac{\partial L}{\partial \Phi^A} - \frac{\mathrm{d}}{\mathrm{d}(A)}\frac{\partial L}{\partial \dot{\Phi}^A} = 0 \tag{11.5.54}$$

However, since this writing is not very convenient, it is customary to write the partial differentials (using the natural units of physics) of the components $\partial/\partial t$, $\partial/\partial y$, $\partial/\partial z$, $\partial/\partial x$ in the form ∂_μ, which finally gives us the "Lagrangian field equations":

$$\boxed{\frac{\partial L}{\partial \Phi^A} - \partial_\mu \left(\frac{\partial L}{\partial(\partial_\mu \Phi^A)}\right) = 0} \tag{11.5.55}$$

Obviously, if we do not use natural units, we should adopt the notation:

$$\partial_\mu = \left(\frac{\partial}{c\partial t}, \frac{\partial}{\partial x}, \frac{\partial}{\partial y}, \frac{\partial}{\partial z}\right) \tag{11.5.56}$$

The fact that the partial derivation ∂_μ now acts on all the components and not only on t is due to the change of generalized coordinate q function only from t to a function of the field Φ^A dependent on x, y, z and t. The reason for this lies in the fact that time and spatial coordinates play the same role, that of describing the space-time continuum on which the physical system evolves.

This also leads us to write the principle of least action in the following form:

$$\begin{gathered}\delta S(q,\dot{q}) = \int \delta L \mathrm{d}t = 0 \\ \Rightarrow \delta S(\Phi^A, \dot{\Phi}^A) = \int \frac{\delta L}{\delta \Phi^A}\delta\Phi^A \mathrm{d}x^4 = \int \frac{\partial L}{\partial \Phi^A}\delta\Phi \mathrm{d}x^4 = 0\end{gathered} \tag{11.5.57}$$

With the action of fields denoted more traditionally:

$$S = \int L(\Phi^A, \dot{\Phi}^A, \partial_\mu \Phi^A)\mathrm{d}x^3\mathrm{d}t = \int L(\Phi^A, \dot{\Phi}^A, \partial_\mu \Phi^A)\mathrm{d}x^4 \tag{11.5.58}$$

or to differentiate Lagrangian and Lagrangian density (we "stylized" sometimes the L to makes the difference between the both):

$$\boxed{S = \int \mathcal{L}(\Phi^A, \dot{\Phi}^A, \partial_\mu \Phi^A)\mathrm{d}x^4} \tag{11.5.59}$$

to be compared to the action of the particle:

$$S(q,\dot{q}) = \int_{t_\lambda}^{t_s} L(q,\dot{q})\mathrm{d}t \tag{11.5.60}$$

In analogy with $p_n=\dfrac{\partial L}{\partial \dot{q}_n}$, we will write:

$$\prod_A=\frac{\partial L}{\partial(\partial_\mu \Phi^A)}=\frac{\partial L}{\partial \dot{\Phi}^A} \tag{11.5.61}$$

and in analogy with $H=\sum p_n\dot{q}_n-L$ we write:

$$H=\sum\prod_A \dot{\Phi}^A-L \tag{11.5.62}$$

But a field is a continuous medium! The sigma sum is therefore no longer adapted and we must move to an integration over all space-time such that:

$$H=\int\prod_A \dot{\Phi}^A\mathrm{d}^4x-L \tag{11.5.63}$$

In analogy with the Heisenberg equations of motion (this way of doing things is often named the "principle of correspondence"), we write:

$$\begin{cases}\dot{q}_n=\dfrac{\partial H}{\partial p_n}\\ \dot{p}_n=-\dfrac{\partial H}{\partial q_n}\end{cases}\Leftrightarrow\begin{cases}\Phi^A=\dfrac{\partial H}{\partial \prod_A}\\ \dot{\prod}_A=-\dfrac{\partial H}{\partial \Phi^A}\end{cases} \tag{11.5.64}$$

Let us now turn to quantum theory by postulating corresponding of "Heisenberg field operators". Let us recall that we had obtained earlier above that:

$$\dot{q}_n=-\frac{\mathrm{i}}{\hbar}[q_n,H],\dot{p}_n=-\frac{\mathrm{i}}{\hbar}[p_n,H]\quad\text{and}\quad[q_n,q_m]=[p_n,p_m]=0,[q_n,p_m]=\mathrm{i}\hbar\delta_{nm} \tag{11.5.65}$$

which gives us:

$$\dot{\Phi}^A=-\frac{\mathrm{i}}{\hbar}\left[\Phi^A,H\right],\dot{\prod}^A=-\frac{\mathrm{i}}{\hbar}\left[\prod^A,H\right]\quad\text{and}\quad\left[\Phi^A,\Phi^B\right]=\left[\prod^A,\prod^B\right]=0,\left[\Phi^A,\prod^B\right]=\mathrm{i}\hbar\delta^3_{AB} \tag{11.5.66}$$

If we summarize a little and we display the comparison with Wave Quantum Physics, we have finally:

1. In Wave Quantum Physics (it's nice to look at it isn't it?):

$$\boxed{\begin{array}{l}p_n=\dfrac{\partial L}{\partial \dot{q}_n}\quad\text{and}\quad H=\sum p_n\dot{q}_n-L\\ \begin{cases}\dot{q}_n=\dfrac{\partial H}{\partial p_n}\\ \dot{p}_n=-\dfrac{\partial H}{\partial q_n}\end{cases}\quad\text{and}\quad\begin{cases}\dot{q}_n=-\dfrac{\mathrm{i}}{\hbar}[q_n,H]\\ \dot{p}_n=-\dfrac{\mathrm{i}}{\hbar}[p_n,H]\end{cases}\\ \begin{cases}[q_n,q_m]=[p_n,p_m]=0\\ [q_n,p_m]=\mathrm{i}\hbar\delta_{nm}\end{cases}\end{array}} \tag{11.5.67}$$

2. And the equivalent by the principle of correspondence in Quantum Field Theory (here it don't just look nice... it becomes art!):

$$\boxed{\begin{array}{l} \prod_A=\dfrac{\partial L}{\partial\dot{\Phi}^A} \quad \text{and} \quad H=\displaystyle\int\prod_A\dot{\Phi}^A\mathrm{d}^4x-L \\ \begin{cases}\Phi^A=\dfrac{\partial H}{\partial\prod_A}\\ \dot{\prod}_A=-\dfrac{\partial H}{\partial\Phi^A}\end{cases} \quad \text{and} \quad \begin{cases}\dot{\Phi}^A=-\dfrac{\mathrm{i}}{\hbar}\left[\Phi^A,H\right]\\ \dot{\prod}^A=-\dfrac{\mathrm{i}}{\hbar}\left[\prod^A,H\right]\end{cases} \\ \begin{cases}\left[\Phi^A,\Phi^B\right]=\left[\prod^A,\prod^B\right]=0\\ \left[\Phi^A,\prod^B\right]=\mathrm{i}\hbar\delta^3_{AB}\end{cases}\end{array}} \qquad (11.5.68)$$

And voila! We have just passed from the parameters of Wave Quantum Physics where the punctual bodies are described by wave functions, to a Quantum Physics where the punctual bodies become continuous fields.

It remains only to apply this general scheme to concrete examples:

We will start with a first example taking into account the relativistic aspect. Thus, the simplest non-trivial Lagrangian density that we can construct is of the form (you will see immediately what it will lead us to, which will confirm its theoretical validity - moreover, the development that follows could very well have been presented backwards):

$$\boxed{L=-\frac{1}{2}\partial_\mu\Phi^A\partial^\mu\Phi^A-\frac{1}{2}m_0^2(\Phi^A)^2} \qquad (11.5.69)$$

Or more explicitly:

$$L=\underbrace{-\frac{1}{2}\partial_0\Phi^A\partial^0\Phi^A}_{\text{kinetic energy term of }L}-\underbrace{\left(\frac{1}{2}\underbrace{\partial_k\Phi^A\partial^k\Phi^A}_{\substack{\text{Einstein summation}\\\text{only on the}\\\text{spatial components}}}+\underbrace{\frac{1}{2}m_0^2(\Phi^A)^2}_{\text{mass term}}\right)}_{\text{potential energy term of }L}=T-V \qquad (11.5.70)$$

that the physicists name "scalar field for a free and spinless particle" or "Klein-Gordon Lagrangian" for a spin-free particle where we use the usual condensed notations:

$$\partial_\mu\Phi^A=\frac{\partial\Phi^A}{\partial x_\mu} \qquad \partial_\mu\Phi^A\partial^\mu\Phi^A=\sum_\mu\partial_\mu\Phi^A\partial^\mu\Phi^A \qquad (11.5.71)$$

and the natural units:

$$\hbar=c=1 \qquad (11.5.72)$$

Otherwise in the S.I. units, we have:

$$L=-\frac{1}{2}\partial_\mu\Phi^A\partial^\mu\Phi^A-\frac{c^2m_0^2}{2\hbar^2}(\Phi^A)^2 \qquad (11.5.73)$$

With c and $\hbar$ set to 1, energy has the unit of $[\text{m}^{-1}]$ and the 4D integral of the Lagrangian density is dimensionless as $\hbar$. It means that the Lagrangian density is of the unit $[\text{m}^{-4}]$, so $\partial_\mu\phi$ is of the unit $[\text{m}^{-2}]$ and ϕ of the unit $[\text{m}^{-1}]$.

In S.I. units we start with the fact that that $\mathcal{L}$ has units of energy density (i.e. $[\text{J}\cdot\text{m}^{-3}]$). Hence using the fact that ${}^{c^2m_0^2}/_{2\hbar^2}(\Phi^A)^2$ must have the same units, we conclude that Φ^A has for units $[\text{J}^{-1/2}\cdot\text{m}^{-1/2}]$.

Let us calculate the Euler-Lagrange equation relative to it (normally it is trivial) without forgetting that it is a functional derivative, which greatly simplifies the calculation:

$$\frac{\partial L}{\partial\Phi^A}-\partial_\mu\left(\frac{\partial L}{\partial(\partial_\mu\Phi^A)}\right)=-m_0^2\Phi^A+\partial_\mu\partial^\mu\Phi^A \tag{11.5.74}$$

Following the request of a reader here are the details allowing to arrive at this result:

$$\begin{aligned}
&\frac{\partial L}{\partial\Phi^A}-\partial_\mu\left(\frac{\partial L}{\partial(\partial_\mu\Phi^A)}\right)\\
&=\frac{\partial\left(-\frac{1}{2}\partial_0\Phi^A\partial^0\Phi^A-\left(\frac{1}{2}\partial_\mu\Phi^A\partial^\mu\Phi^A+\frac{1}{2}m_0^2(\Phi^A)^2\right)\right)}{\partial\Phi^A}\\
&-\partial_\mu\left(\frac{\partial\left(-\frac{1}{2}\partial_0\Phi^A\partial^0\Phi^A-\left(\frac{1}{2}\partial_\mu\Phi^A\partial^\mu\Phi^A+\frac{1}{2}m_0^2(\Phi^A)^2\right)\right)}{\partial(\partial_\mu\Phi^A)}\right)\\
&=\frac{\partial\left(-\frac{1}{2}m_0^2(\Phi^A)^2\right)}{\partial\Phi^A}-\partial_\mu\left(\frac{\partial\left(-\frac{1}{2}\partial_\mu\Phi^A\partial^\mu\Phi^A\right)}{\partial(\partial_\mu\Phi^A)}\right)\\
&=-\frac{1}{2}m_0^2\frac{\partial\left((\Phi^A)^2\right)}{\partial\Phi^A}+\frac{1}{2}\partial_\mu\left(\frac{\partial\left(\partial_\mu\Phi^A\partial^\mu\Phi^A\right)}{\partial(\partial_\mu\Phi^A)}\right)\\
&=-m_0^2\Phi^A+\frac{1}{2}\partial_\mu\left(\partial^\mu\Phi^A\right)=-m_0^2\Phi^A+\frac{1}{2}\partial_\mu\partial^\mu\Phi^A
\end{aligned} \tag{11.5.75}$$

Hence the equation of motion in natural units and daring a dangerous notation for the double partial derivative (the Einstein summation is then implicit...):

$$\left(\partial_\mu^2-m_0^2\right)\Phi^A=0 \tag{11.5.76}$$

or as we will quick see it, in order to fall back on the results obtained in the Relativistic Quantum Physics section, we are obliged to introduce the contravariant and covariant differential operator (see section Tensor Calculus page 2059) with the signature $(-,+,+,+)$:

$$\partial^\mu=\left(\frac{\partial^2}{c^2\partial t^2},\frac{\partial^2}{\partial x^2},\frac{\partial^2}{\partial y^2},\frac{\partial^2}{\partial z^2}\right)=\left(\frac{\partial^2}{c^2\partial t^2},\vec{\nabla}^2\right) \tag{11.5.77}$$

$$\partial_\mu=\eta_{\mu\nu}\partial^\nu=\left(-\frac{\partial^2}{c^2\partial t^2},\frac{\partial^2}{\partial x^2},\frac{\partial^2}{\partial y^2},\frac{\partial^2}{\partial z^2}\right)=\left(\frac{-\partial^2}{c^2\partial t^2},\vec{\nabla}^2\right) \tag{11.5.78}$$

Let us recall now for comparison purpose that in the section of Wave Quantum Physics we had obtained the following free Klein-Gordon equation:

$$\left(\hbar^2\Box - m_0^2c^2\right)\Psi = 0 \tag{11.5.79}$$

also with the signature $(-,+,+,+)$ thus with the Alembertien operator:

$$\Box = -\frac{\partial^2}{c^2\partial t^2}+\frac{\partial^2}{\partial x^2}+\frac{\partial^2}{\partial y^2}+\frac{\partial^2}{\partial z^2} \tag{11.5.80}$$

We then have a perfect correspondence between the free Klein-Gordon equation and the field equation (written below in natural units as usual):

$$\left(\partial_\mu^2 - m_0^2\right)\Psi = 0 \quad \text{and} \quad \left(\partial_\mu^2 - m_0^2\right)\Phi^A = 0 \tag{11.5.81}$$

and it is here that one can eventually feel a shiver in the back and stay admiring in front of the power of mathematical formalism opening new perspectives on how to see the gears of our Universe... Thus, in Quantum Field Theory, the Klein-Gordon equation can be reinterpreted as a field equation!

The form of the free Klein-Gordon equation involving fields is sometimes named the "Klein-Gordon field equation".

Remark

We can generalize the Klein-Gordon field equation to curved space. Indeed, as:

$$\partial_\mu\Phi^A\partial^\mu\Phi^A = g_{\nu\mu}\partial^\nu\Phi^A\partial^\mu\Phi^A \tag{11.5.82}$$

and therefore:

$$L = -\frac{1}{2}g_{\nu\mu}\partial^\nu\Phi^A\partial^\mu\Phi^A - \frac{1}{2}m_0^2(\Phi^A)^2 \tag{11.5.83}$$

Then the action S must be corrected using the invariant volume introduced in the section of Tensor Calculus such that:

$$\boxed{S = \int \mathcal{L}\mathrm{d}x^4 = \int\left(-\frac{1}{2}g_{\nu\mu}\partial^\nu\Phi^A\partial^\mu\Phi^A - \frac{1}{2}m_0^2(\Phi^A)^2\right)\sqrt{g}\mathrm{d}x^4} \tag{11.5.84}$$

And even... better ... you will see, we'll do it a little in a blind way ... and therefore!!!: Let us now consider the following Lagrangian (which we assume will be obtained by successive trials and errors... but again we could have done the development backwards), intending to express the "Lagrangian interaction of an electromagnetic field with a current density":

$$\boxed{L = \frac{1}{4}F^{\mu\nu}F_{\mu\nu} - j^\nu A_\nu} \tag{11.5.85}$$

where we recognize there the tensors of the electromagnetic field proved and determined in the section of Electrodynamics (see page 4128) and Special Relativity and for which, for recall, we have:

$$F^{\mu\nu} = \partial_\mu A_\nu - \partial_\nu A_\mu \tag{11.5.86}$$

In this Lagrangian, let us treat the vector potential as a field such that:

$$\frac{\partial L}{\partial \Phi^A}-\partial_\mu\left(\frac{\partial L}{\partial(\partial_\mu \Phi^A)}\right)=\frac{\partial L}{\partial A_\nu}-\partial_\mu\left(\frac{\partial L}{\partial(\partial_\mu A_\nu)}\right)=0 \qquad (11.5.87)$$

Therefore, by decomposing the developments, we get very easily:

$$\frac{\partial(j^\nu A_\nu)}{\partial(\partial_\mu A_\nu)}=0 \quad \text{and} \quad \frac{\partial(j^\nu A_\nu)}{\partial A_\nu}=j^\nu \quad \text{and} \quad \frac{\partial(F^{\alpha\beta}F_{\alpha\beta})}{\partial A_\nu}=0 \qquad (11.5.88)$$

In a first step, the reader will verify by doing some relatively elementary tensor calculus that:

$$\frac{\partial F_{\alpha\beta}}{\partial(\partial_\mu A_\nu)}=\frac{\partial(\partial_\alpha A_\beta-\partial_\beta A_\alpha)}{\partial(\partial_\mu A_\nu)}=\delta_\alpha^\mu\delta_\beta^\nu-\delta_\beta^\mu\delta_\alpha^\nu \qquad (11.5.89)$$

Then:

$$\begin{aligned}\frac{\partial(F^{\alpha\beta}F_{\alpha\beta})}{\partial(\partial_\mu A_\nu)}&=F^{\alpha\beta}\frac{\partial F_{\alpha\beta}}{\partial(\partial_\mu A_\nu)}+\frac{\partial F^{\alpha\beta}}{\partial(\partial_\mu A_\nu)}F_{\alpha\beta}=2\frac{\partial F_{\alpha\beta}}{\partial(\partial_\mu A_\nu)}F^{\alpha\beta}\\&=2[\delta_\alpha^\mu\delta_\beta^\nu-\delta_\beta^\mu\delta_\alpha^\nu]F^{\alpha\beta}=2[F^{\mu\nu}-F^{\nu\mu}]=4F^{\mu\nu}\end{aligned} \qquad (11.5.90)$$

Therefore, the equation of the field is written:

$$\frac{\partial L}{\partial A_\nu}-\partial_\mu\left(\frac{\partial L}{\partial(\partial_\mu A_\nu)}\right)=j^\nu-\partial_\mu\left(\frac{1}{4}4F^{\mu\nu}\right)=0 \qquad (11.5.91)$$

hence:

$$\partial_\mu F^{\mu\nu}=j^\nu \qquad (11.5.92)$$

We must admit that the result is quite beautiful even if the approach is not the most rigorous one! We thus fall back on the Maxwell equation with sources with the same Lagrangian of the field (see section Electrodynamics page 4131). Thus, this massless Lagrangian is assimilated to the Lagrangian of the vector field of spin 1 assimilated to the bosons (see section Statistical Mechanics page 3571).

Let us recall now that we had obtained in the section on Electrodynamics (see page 4126) the following action for a charged particle in an electromagnetic field (before a long development which had brought us to the tensor of the electromagnetic field...):

$$S=\int_\alpha^\beta -m_0c\mathrm{d}s-qA^i\mathrm{d}x_i \qquad (11.5.93)$$

and remembering that (see section Electrodynamics page 4126):

$$\frac{\mathrm{d}s}{\mathrm{d}t}=c\sqrt{1-\frac{v^2}{c^2}} \qquad (11.5.94)$$

it comes:

$$S=\int_\alpha^\beta\left(-m_0c^2\sqrt{1-\frac{v^2}{c^2}}-qA^i\mathrm{d}v_i\right)\mathrm{d}t \qquad (11.5.95)$$

The corresponding Lagrangian density is therefore:

$$L = -\rho_0 c^2\sqrt{1-\frac{v^2}{c^2}} - j^\nu A_\nu \tag{11.5.96}$$

So we have finally:

1. The Lagrangian (Lagrangian density) of a charged particle in an electromagnetic field (which we have just obtained):

$$L = -\rho_0 c\sqrt{1-\frac{v^2}{c^2}} - j^\nu A_\nu \tag{11.5.97}$$

2. The Lagrangian (Lagrangian density) we get just before (which allowed us to fall back on Maxwell's equations with sources):

$$L = \frac{1}{4}F^{\mu\nu}F_{\mu\nu} - j^\nu A_\nu \tag{11.5.98}$$

Hence, it is natural to write the "Lagrangian (total Lagrangian density) of the electromagnetic field":

$$\boxed{L = -\rho_0 c^2\sqrt{1-\frac{v^2}{c^2}} - j^\nu A_\nu + \frac{1}{4\mu_0}F^{\mu\nu}F_{\mu\nu}} \tag{11.5.99}$$

Let us now continue our way with the free Dirac equation! Let us recall that in the Relativistic Quantum Physics section we obtained the free Dirac equation (see page 4931) in the form (basically, let us also recall that it is a relativistic equation):

$$(\mathrm{i}\gamma^\mu\partial_\mu - m_0)\,\Psi = (\mathrm{i}\not{\partial} - m_0)\,\Psi = 0 \tag{11.5.100}$$

Now let us recall (see section Linear Algebra page 1951) that $(AB)^\dagger = B^\dagger A^\dagger$. Therefore, it comes:

$$((\mathrm{i}\not{\partial} - m_0)\,\Psi)^\dagger = 0^\dagger \Rightarrow \Psi^\dagger\,(\mathrm{i}\not{\partial} - m_0)^\dagger = \Psi^\dagger\left(\mathrm{i}^\dagger\not{\partial}^\dagger - m_0\right) = \Psi^\dagger\left(-\mathrm{i}\gamma^{\mu\dagger}\partial_\mu^\dagger - m_0\right) = 0 \tag{11.5.101}$$

where we have introduced the "Feynman slash notation" $\not{\partial}$ (less commonly known as the "Dirac slash notation").

But, $\partial_\mu^\dagger = \partial_\mu$ and it is super easy to verify (do not forget that we use the Dirac representative form of Pauli matrices!!!):

$$\gamma^{\mu\dagger} = \gamma^0\gamma^\mu\gamma^0 \tag{11.5.102}$$

which leads us to write:

$$\Psi^\dagger\left(-\mathrm{i}\gamma^0\gamma^\mu\gamma^0\partial_\mu - m_0\right) = 0 \tag{11.5.103}$$

It is then convenient to introduce the "Dirac adjoint" or "adjoint spinor":

$$\boxed{\bar{\Psi} = \bar{\Psi}^T\gamma^0 = \Psi^\dagger\gamma^0 = \left(\bar{\Psi}_1, \bar{\Psi}_2, -\bar{\Psi}_3, -\bar{\Psi}_4\right)} \tag{11.5.104}$$

Sadly this notation may be misleading ast the adjoint spinor $\bar{\Psi}$ can be confused with the complex conjugate $\bar{\Psi}$ because they have exactly the same notation! That's why in many textbooks the above is instead denoted as:

$$\bar{\Psi}=\Psi^{\dagger}\gamma^0=(\Psi^*)^T\gamma^0=(\Psi^*,\Psi^*,\Psi^*,\Psi^*)\begin{pmatrix}1&0&0&0\\0&1&0&0\\0&0&-1&0\\0&0&0&-1\end{pmatrix}\tag{11.5.105}$$

Remark

Let us recall that Ψ is a matrix-column and $\Psi^{\dagger}$ a matrix-line. So it comes that $\bar{\Psi}$ is also a matrix-line!

Using the fact that in the Dirac representation $\gamma^0\gamma^0=\mathbb{1}$ we can write:

$$\begin{aligned}&\Psi^{\dagger}\left(-\mathrm{i}\gamma^0\gamma^{\mu}\gamma^0\partial_{\mu}-m_0\mathbb{1}\right)=0\\&\Rightarrow\Psi^{\dagger}\left(-\mathrm{i}\gamma^0\gamma^{\mu}\gamma^0\partial_{\mu}-m_0\gamma^0\gamma^0\right)=0\\&\Rightarrow\Psi^{\dagger}\gamma^0\left(-\mathrm{i}\gamma^{\mu}\gamma^0\partial_{\mu}-m_0\gamma^0\right)=0\\&\Rightarrow\bar{\Psi}\left(-\mathrm{i}\gamma^{\mu}\gamma^0\partial_{\mu}-m_0\gamma^0\right)=0\\&\Rightarrow\bar{\Psi}\left(\mathrm{i}\gamma^{\mu}\gamma^0\partial_{\mu}+m_0\gamma^0\right)=0\end{aligned}\tag{11.5.106}$$

by simplifying the γ^0 it comes the "free adjoint Dirac equation":

$$\bar{\Psi}\left(\mathrm{i}\gamma^{\mu}\partial_{\mu}+m_0\right)=\bar{\Psi}\left(i\not{\partial}+m_0\right)=0\tag{11.5.107}$$

What we traditionally write:

$$\boxed{\bar{\Psi}\left(\mathrm{i}\overleftarrow{\not{\partial}}+m_0\right)=0}\tag{11.5.108}$$

The notation $\overleftarrow{\not{\partial}}$ meaning that the operator $\not{\partial}$ operates on $\bar{\Psi}$ on the left such that:

$$\bar{\Psi}\overleftarrow{\not{\partial}}=\left(\partial_{\mu}\bar{\Psi}\right)\gamma^{\mu}\tag{11.5.109}$$

Remark

Some authors write $(\mathrm{i}\not{\partial}+m_0)\bar{\Psi}=0$ but this is false because $\bar{\Psi}$ is a line matrix as we pointed out above !!!

Finally we have for the free Dirac equations:

$$\boxed{\begin{aligned}\left(\mathrm{i}\overleftarrow{\not{\partial}}+m_0\right)\Psi=0\Leftrightarrow\mathrm{i}\gamma^{\mu}\partial_{\mu}\Psi-m_0\Psi=0\\\bar{\Psi}\left(\mathrm{i}\overleftarrow{\not{\partial}}+m_0\right)=0\Leftrightarrow\mathrm{i}\left(\partial_{\mu}\bar{\Psi}\right)\gamma^{\mu}+m_0\Psi=0\end{aligned}}\tag{11.5.110}$$

Let us now suppose that the "Lagrangian of the free Dirac spinor field" is of the form (because in the end it is the Lagrangian that interests us!):

$$\boxed{L=\bar{\Psi}\left(\mathrm{i}\gamma^{\mu}\partial_{\mu}-m_0\right)\Psi}\tag{11.5.111}$$

where we have for recall $\bar{\Psi}=\Psi^{\dagger}\gamma^0$. It is therefore the Lagrangian of the spinor field for the particles of spin $1/2$ which are therefore free fermions.

Remark

Now, I take Ψ and rotate it by some angle in the complex plane. This means that I multiply it by $e^{\mathrm{i}\theta}$ for some angle θ. Note that the rotation is not a physical rotation in space-time, it's just a redefinition of the values of the field Ψ. You can think of it as a rotation in some internal mathematical space.

Recall that the kinetic term in the Lagrangian has a product of Ψ and its complex conjugate $\bar{\Psi}$. If I replace Ψ with $e^{\mathrm{i}\theta}\Psi$, I also need to replace $\bar{\Psi}$ with $\bar{\Psi}e^{-\mathrm{i}\theta}$, where the minus sign in the exponent comes from complex conjugation.

Therefore the product $\bar{\Psi}\Psi$ becomes $\bar{\Psi}e^{-\mathrm{i}\theta}e^{\mathrm{i}\theta}\Psi$. Obviously, the two exponents cancel each other, and we get $\bar{\Psi}\Psi$ again.

This means that the Lagrangian is invariant to rotation of the field Ψ by a complex phase. A fancier way of saying this is that the Lagrangian possesses $U(1)$ symmetry. $U(1)$ is the circle group, or the group of complex numbers with absolute value 1, that is, the complex numbers of the form $e^{\mathrm{i}\theta}$.

Now, remember that Noether's theorem (see section Mechanics page 3132) says that for any symmetry of the Lagrangian there is a conserved quantity. This symmetry is, of course, no exception as it is the symmetry for the conservation of charge!

Considering the quantities $\bar{\Psi}$, Ψ as independent (this is what they are anyway since they are orthogonal) and choosing the spinor field as being $\Psi^{\dagger}$, we have the Euler-Lagrange equation:

$$\frac{\partial L}{\partial\bar{\Psi}}-\partial_{\mu}\left(\frac{\partial L}{\partial(\partial_{\mu}\bar{\Psi})}\right)=0 \tag{11.5.112}$$

The second term is equal to zero since the Dirac Lagrangian does not contain terms with $\partial_{\mu}\Psi^{\dagger}$. In fact it remains:

$$\frac{\partial L}{\partial\bar{\Psi}}=\frac{\partial\left(\bar{\Psi}\mathrm{i}\gamma^{\mu}\partial_{\mu}\Psi-\bar{\Psi}\right)}{\partial\bar{\Psi}}=\mathrm{i}\gamma^{\mu}\partial_{\mu}\Psi-\Psi m_0=(\mathrm{i}\not{\partial}-m_0)\,\Psi=0 \tag{11.5.113}$$

So we fall back on the free Dirac equation (the same development that can be done for the free adjoint Dirac equation)! Thus, in this framework, the only way to explain the quantum properties of the material containing particles with spin $1/2$ is to involve the fields $\bar{\Psi}$, Ψ representing electrically charged particles, electrons and positrons as we know. We then name then these entities "Dirac field" also named "spinor field" or spin $1/2$ fermion field ".

Remark

Often, when using the Dirac equation one finds the slash notation introduced in the section of Relativistic Quantum Physics used on four-momentum. Using the Dirac basis for the gamma matrices:

$$\gamma^0=\begin{pmatrix}\mathbb{1} & 0\\ 0 & -\mathbb{1}\end{pmatrix}\qquad \gamma^i=\begin{pmatrix}0 & \sigma^i\\ -\sigma^i & 0\end{pmatrix} \tag{11.5.114}$$

as well as the definition of four momentum (see section Special Relativity page 5687):

$$p_{\mu}=(E,-p_x,-p_y,-p_z) \tag{11.5.115}$$

we see explicitly that:

$$\not{p}=\gamma^\mu p_\mu=\gamma^0 p_0+\gamma^i p_i=\begin{bmatrix} p_0 & 0 \\ 0 & -p_0 \end{bmatrix}+\begin{bmatrix} 0 & \sigma^i p_i \\ -\sigma^i p_i & 0 \end{bmatrix}=\begin{bmatrix} E & -\sigma\circ\vec{p} \\ \sigma\circ\vec{p} & -E \end{bmatrix} \tag{11.5.116}$$

Similar results hold in other bases, such as the Weyl basis.

Now, to make the reader able to understand some other traditional notation used by practitioners (and useful to simplified some proofs), let us introduce matrix γ_5 taken to be:

$$\gamma_5=\begin{bmatrix} -\mathbb{1} & 0 \\ 0 & \mathbb{1} \end{bmatrix} \tag{11.5.117}$$

Let us write the four component Dirac spinors as sum of left and right chirality components, i.e.:

$$\begin{aligned} \Psi_L&=\frac{1}{2}\left(1-\gamma^5\right)\Psi \\ \Psi_R&=\frac{1}{2}\left(1+\gamma^5\right)\Psi \end{aligned} \tag{11.5.118}$$

where the 1 above represents a 4×4 diagonal matrix with only 1 in the diagonal!

Adopting the 'spin-up', 'spin-down' notation in quantum mechanics, we can write :

$$\Psi_L=\begin{pmatrix} \Psi_{L_\uparrow} \\ \Psi_{L_\downarrow} \end{pmatrix} \text{ and } \Psi_R=\begin{pmatrix} \Psi_{R\uparrow} \\ \Psi_{R_\downarrow} \end{pmatrix} \tag{11.5.119}$$

Remark

We define therefore the "projection operators" as:

$$\hat{P}_L=\frac{1-\gamma_5}{2},\qquad \hat{P}_R=\frac{1+\gamma_5}{2} \tag{11.5.120}$$

as (therefore they commute) $\hat{P}_L\hat{P}_R=\hat{P}_R\hat{P}_L=0$.

We can write:

$$\Psi=\Psi_L+\Psi_R \tag{11.5.121}$$

Substituting this in the above Lagrangian we get:

$$\begin{aligned} L&=\left(\bar{\Psi}_L+\bar{\Psi}_R\right)\left(\gamma^\mu \mathrm{i}\partial_\mu-m\right)\left(\Psi_L+\Psi_R\right) \\ &=\left(\bar{\Psi}_L+\bar{\Psi}_R\right)\left(\gamma^\mu \mathrm{i}\partial_\mu\right)\left(\Psi_L+\Psi_R\right)-m\left(\bar{\Psi}_L+\bar{\Psi}_R\right)\left(\Psi_L+\Psi_R\right) \\ &=\left(\Psi_L^\dagger\gamma^0+\Psi_R^\dagger\gamma^0\right)\left(\gamma^\mu \mathrm{i}\partial_\mu\right)\left(\Psi_L+\Psi_R\right)-m\left(\bar{\Psi}_L\Psi_L+\bar{\Psi}_R\Psi_L+\bar{\Psi}_L\Psi_R+\bar{\Psi}_R\Psi_R\right) \\ &=\left(\Psi_L^\dagger\gamma^0\left(\gamma^\mu \mathrm{i}\partial_\mu\right)\Psi_L+\Psi_L^\dagger\gamma^0\left(\gamma^\mu \mathrm{i}\partial_\mu\right)\Psi_R+\Psi_R^\dagger\gamma^0\left(\gamma^\mu \mathrm{i}\partial_\mu\right)\Psi_L+\Psi_R^\dagger\gamma^0\left(\gamma^\mu \mathrm{i}\partial_\mu\right)\Psi_R\right)-m \\ &\left(\bar{\Psi}_L\Psi_L+\bar{\Psi}_R\Psi_L+\bar{\Psi}_L\Psi_R+\bar{\Psi}_R\psi_R\right) \end{aligned} \tag{11.5.122}$$

Now using above definition of Ψ_L and Ψ_R and using:

$$\gamma^5\gamma^0=-\gamma^0\gamma^5 \text{ and } \gamma^5\gamma^\mu=-\gamma^\mu\gamma^5 \tag{11.5.123}$$

We get:

$$L=\bar{\Psi}_L\gamma^\mu i\partial_\mu\Psi_L+\bar{\Psi}_R\gamma^\mu i\partial_\mu\Psi_R-m\left(\bar{\Psi}_R\psi_L+\bar{\Psi}_L\Psi_R\right) \tag{11.5.124}$$

At this point, the reader must know, that at our actual level of knowledge, all fields have particles, while all particles are quanta of fields. That's why the equations used to describe the physics of the Standard Model are named "Quantum Field Theory", not "Quantum Particle Theory".

11.5.2.1 Field interactions ($\lambda\varphi^4$ theory)

Let us remind that we have derive earlier above in natural units:

$$L=\underbrace{-\frac{1}{2}\partial_0\Phi^A\partial^0\Phi^A}_{\text{kinetic energy term of } L}-\underbrace{\left(\frac{1}{2}\underbrace{\partial_k\Phi^A\partial^k\Phi^A}_{\substack{\text{Einstein summation}\\\text{only on the}\\\text{spatial components}}}+\underbrace{\frac{1}{2}m_0^2(\Phi^A)^2}_{\text{mass term}}\right)}_{\text{potential energy term of } L}=T-V \tag{11.5.125}$$

Also often denoted:

$$\mathcal{L}=T-V=\frac{1}{2}\partial_\mu\varphi\partial^\mu\varphi-V(\varphi) \tag{11.5.126}$$

Now to consider physically interesting theories we need to specialize or restrict ourselves to some specific forms of the potential function, $V(\varphi)$. One physical such restriction is that the potential should be an analytic function in φ. At the level of classical theory one might not be able to appreciate the significance of this restriction, but in quantum theory it will become evident that non-analytic potentials or terms in the action will imply or result in breakdown of effective field theory description at some regions of moduli space. Foreseeing this situation we will strictly consider analytic potentials, $V(\varphi)$ and since analytic functions as a power series:

$$V(\varphi)=\sum_{n=0}^{+\infty}a_n\varphi^n=a_0+a_1\varphi+a_2\varphi^2+a_3\varphi^3+a_4\varphi^4+\ldots:=\sum_{n=0}^{+\infty}\frac{\lambda_n}{n!}\varphi^n \tag{11.5.127}$$

Now the odd-power terms, $V_{\text{odd}}=a_1\varphi, a_3\varphi^3$ etc. have a pathological property, namely, $V_{\text{odd}}\rightarrow-\infty$ as $\varphi\rightarrow+\infty$.

In Quantum Field Theory (QFT), the behavior of terms in the potential, particularly odd and even powers of fields, can often be understood through symmetry considerations and stability arguments:

- Symmetry in the Lagrangian: Typically, the potential in QFT is constructed to respect certain symmetries of the theory. For example, if the theory involves a scalar field, a common choice is to impose symmetry under a transformation like ($\varphi \rightarrow -\varphi$) (parity symmetry). This symmetry forbids odd powers of the field in the potential because such terms would break the symmetry. Odd terms, when present, often introduce asymmetries that can lead to inconsistencies or instabilities in the field dynamics, particularly under quantization or renormalization.

- Stability Considerations: For a potential to describe a stable system, it needs to have a minimum where the field can "sit." If odd powers dominate, they can lead to a potential that is not bounded from below, creating pathological behavior essentially, the energy becomes unbounded, leading to physical instability. Even terms are preferred as they allow for stable minima and are more consistent with renormalizable interactions.

Pathologies in odd terms often arise in specific contexts where symmetry or stability conditions are violated, leading to unphysical or non-viable theories.

Thus if we keep such odd power terms in the potential energy function, V, they will lead to the potential having no lower bound. Systems which have potentials with no lower bound have no stable ground state, and hence are considered nonphysical. Since we are interested with physical systems we will omit such odd powered terms in the potential function:

$$V(\varphi)=a_2\varphi^2+a_4\varphi^4+\ldots \tag{11.5.128}$$

and we put for the the coefficients, $a_2=\frac{m}{2}$, and $a_4=\frac{\lambda}{4!}$, to make the potential look consistent with the literature:

$$V(\varphi)=\frac{m}{2}\varphi^2+\frac{\lambda}{4!}\varphi^4 \tag{11.5.129}$$

The quadratic piece, $\frac{m}{2}\varphi^2$ is referred to as the "mass term" and the quartic piece, $\frac{\lambda}{4!}\varphi^4$ is referred to as the "(self) coupling term" or "(self) interaction term".

The nomenclature will become obvious further below. It will turn out this restriction to quadratic and quartic potentials will cover a large class of physical systems especially in particle physics and statistical mechanics and is a widely studied system which goes by the name of "$\lambda\varphi^4$ theory". Terms with higher powers of φ, are also undesirable in a fundamental theory since they will lead to quantum theory with no predictive power (non-renormalizable), so we will not consider them. However, for effective field theories such nonrenormalizable terms are fine.

Let's determine the (mass) dimensions of the field, φ, the constants in the potential, m,λ!

Remember that the action has the dimensions of J · s which is identical to the unit of angular momentum and that Planck constant also has the units of an angular momentum. Therefore in natural units, as Planck constant is without dimensions, then the action S is also without dimension in natural units!

From the speed of light being unitless in natural units, we get, $[\mathrm{L}]=[\mathrm{T}]$ (length is time).

We have unit-wise $E=mc^2$ meaning that in natural units $E=m=[\mathrm{J}]$. Furthermore we have $hc=[\mathrm{J}\cdot\mathrm{m}]=[1]$ in natural units, so distance is the same units as energy inverse here, which is same as mass inverse, i.e. $[\mathrm{M}]=[\mathrm{L}]^{-1}$.

That being said, to determine the dimensions of φ, we look at the kinetic term in the action:

$$S=\int\frac{1}{2}\partial_{\mu}\varphi\partial^{\mu}\varphi\mathrm{d}x^4+\ldots \qquad (11.5.130)$$

This means the RHS should have dimension zero as well. Let's look at the dimensions of the RHS. The integration measure, d^4x of course has dimensions as four powers of length, $\mathrm{d}^4x=[\mathrm{L}]^4$. Similarly the derivatives have dimensions of inverse length, $\partial=[\mathrm{L}]^{-1}$. Thus we have:

$$\left[\mathrm{d}^4x\frac{1}{2}\partial_{\mu}\varphi\partial^{\mu}\varphi\right]=\left[\mathrm{L}^2\varphi^2\right] \qquad (11.5.131)$$

But as in natural units $[\mathrm{L}]^2=[\mathrm{M}]^{-2}$ we have therefore that φ has the same dimension as mass in natural units.

These naive dimensions we are determining based on dimensional analysis are referred to the "classical dimensions" or "engineering dimensions" of φ.

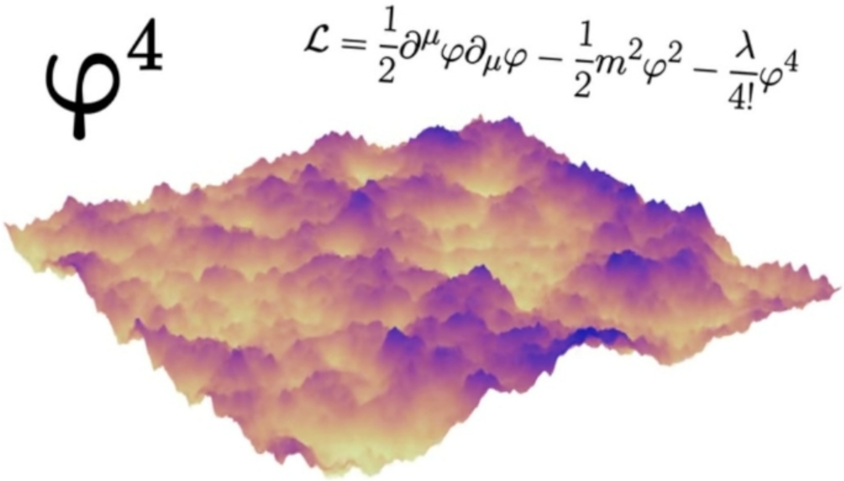
Having determined the dimension of the field φ, it will now be easy to determine the engineering dimensions of the constants, m and λ. Again we start from the fact that the action is dimensionless, so the dimension of each term from the potential energy integral should vanish as well:

$$\left[\int\frac{m}{2}\varphi^2\mathrm{d}^4x\right]=[1] \qquad \left[\int\frac{\lambda}{4!}\varphi^4\mathrm{d}^4x\right]=[1] \qquad (11.5.132)$$

These two conditions immediately imply:

$$[m]=[\mathrm{kg}] \qquad [\lambda]=[1] \qquad (11.5.133)$$

Since the constant, m has dimensions of mass, we are justifying in referring the term $\frac{m}{2!}\varphi^2$ in the lagrangian as the mass term. Later on, when we quantize this theory we will see that indeed, m is (related to) the mass of the quantum of this field (particle). The quartic coupling constant, λ is dimensionless (in $3+1$ space-time dimensions only, in higher or lower dimensions it will have non-zero dimensions).



φ^4
$\mathcal{L}=\frac{1}{2}\partial^{\mu}\varphi\partial_{\mu}\varphi-\frac{1}{2}m^2\varphi^2-\frac{\lambda}{4!}\varphi^4$

Figure 11.148: Artistic representation of quantum fluctuation in an interacting field (source: ScienceClic, author: Alessandro Roussel)

11.5.3 Gauge Theories

We will now see a simple approach to a tool that revolutionized the approach of modern particle physics in the mid-120th century (holocene calendar) and that has earned several Nobel Prizes to those who contributed to it.

We advise very strongly before reading what follows that the reader also take a preliminary look at the sub-section of Gauge Theory of the Electrodynamics section (see page 4115), as it contains a first example of an invariance of Gauge making emerging a field (the vector potential) necessary to explain certain phenomena at the quantum scale as clearly explained by Pauli's equation (see section Relativistic Quantum Physics page 4979).

Since the early 11980s (holocene calendar), popularization magazines have talked a lot when dealing about Quantum Physics on Gauge theories. Electromagnetic interactions and Weak interactions are described jointly by a Gauge theory developed by Glashow, Weinberg and Salam. Strong interactions also seem correctly described by a Gauge theory. It is within the framework of these gauge theories that theoretical physicists try to unify the various fundamental interactions of nature. It is therefore appropriate, even in this textbook which treats in an elementary way of Quantum Physics, to speak of Gauge theory within the framework of this study domain.

To do this, we will already consider the context that led to the discovery of Gauge invariance in the context of Electrodynamics (see the section of the same name at page 4115 for the details) and make a comparison with certain developments seen in the section of General Relativity and the role played by Weyl in the proof of the fundamental principles of a Gauge theory.

Let us recall that the Special Relativity and General Relativity are based on the premise that there is no absolute reference frame in the universe. We have seen in the section of Special Relativity in a long and broad way that the relations which make it possible to pass the laws of physics from one reference frame to another one depend only on the relative speed between them. Thus, Special Relativity is a theory with global symmetry. We have also seen in the section of General Relativity that the affine connection is the link between the referentials of the local theory (weak field approximation) that is General Relativity.

In 11919 (holocene calendar), the first experimental observation of the deviation of the light of a star by the gravitational field of the Sun (actually a G2V-type star, aka yellow dwarf) took place. This spectacular confirmation of the theory of General Relativity inspired Hermann Weyl, who proposed the same year a revolutionary conception of Gauge invariance: If the effects of a gravitational field can be described by a connection expressing the relative orientation between local repositories of space-time, can other forces of nature such as electromagnetism also be associated with similar connections?

We consider two types of Gauge symmetry: one known as "global Gauge" and the other named "local Gauge". They are distinguished by the parameter characterizing the phase change of the wave function (we will see this in detail further below).

11.5.3.1 Global Gauge invariance

We will therefore study the Gauge invariance using the Schrödinger equation and show that even if the results may seem confusing (in the context of complex set $\mathbb{C}$ applications), they nevertheless remain mathematically correct!

Remark

The global gauge invariance is rigorously referred to as "global symmetry".

Let us consider the Schrödinger's equation:

$$H\Psi=\mathrm{i}\hbar\frac{\partial}{\partial t}\Psi \tag{11.5.134}$$

with as we have shown:

$$H=-\frac{\hbar^2}{2m}\vec{\nabla}^2+V \tag{11.5.135}$$

with $\Psi=\Psi(\vec{r},t)$. Either in the case of a free particle:

$$H=-\frac{\hbar^2}{2m}\vec{\nabla}^2=\hbar^2\frac{(-\mathrm{i}\vec{\nabla})^2}{2m} \tag{11.5.136}$$

This operator is obviously invariant in the transformation which passes from Ψ to Ψ' with (change of the phase of a plane wave by an angle α):

$$\Psi'=e^{\mathrm{i}g\alpha}\Psi\Rightarrow\Psi=e^{-\mathrm{i}g\alpha}\Psi' \tag{11.5.137}$$

where g is a coupling constant (to ensure the homogeneity of the units and the amplitude) being considered as a real number and α a real parameter independent of the coordinates (in a first time ...) of space and time.

Then:

$$H\Psi=\mathrm{i}\hbar\frac{\partial}{\partial t}\Psi \tag{11.5.138}$$

becomes:

$$He^{-\mathrm{i}g\alpha}\Psi'=\mathrm{i}\hbar\frac{\partial}{\partial t}e^{-\mathrm{i}g\alpha}\Psi' \tag{11.5.139}$$

and as α does not depend on x, y, z, t then:

$$e^{-\mathrm{i}g\alpha}H\Psi'=e^{-\mathrm{i}g\alpha}\mathrm{i}\hbar\frac{\partial}{\partial t}\Psi' \tag{11.5.140}$$

Either after simplification:

$$H\Psi'=\mathrm{i}\hbar\frac{\partial}{\partial t}\Psi' \tag{11.5.141}$$

The form of the equation remained the same when we made the change from Ψ to Ψ'.

Thus, the description of a free system is not affected by the global phase change. In the language of group theory (see section Set Algebra page 1424), we speak of invariance under the $\text{U}(1)$ group of phases.

In other words to speak like the physicists...:

$$e^{\text{i}g\alpha}\Psi \tag{11.5.142}$$

defines a Gauge transformation by the rotation α (the parameter in the sense of the Lie groups) in the complex plane (but that corresponds to a phase change in the field of wave theory).

The set of rotations forms a group denoted $\text{U}(1)$ which the usage make we name it the "gauge group" (isomorphic to $\text{SO}(2)$ as we have seen it in the section of Set Algebra).

The set of all $e^{\text{i}g\alpha}$ forms a monodimensional representation of the group $\text{U}(1)$ which we name the "representation g". There is, of course, an infinity of representations g (as much as there are values of g!).

Since the parameter α does not depend on position and time, we say that the system is "invariant by global gauge" transformation (everywhere at the same time) or simply an invariant of $\text{U}(1)$ in time and space.

Remark

In fact, global Gauge transformations are a subset of local gauge transformation: changing the same amount everywhere is a special case (i.e., more restricting) of changing the phase of each point independently. A local Gauge transformation is therefore not a subset of a global Gauge transformation. In this respect the name is a bit misleading.

11.5.3.2 Local Gauge invariance

But but... either the global gauge invariance shows that we have an equation that remains valid as part of a fixed phase change. But now in a laboratory this Schrödinger equation must be valid even if the phase depends on position and time. This constraint is named a "local gauge invariance".

We consider this time that α is a function $\alpha(\vec{r},t)$ and the idea obviously is to check whether the Schrödinger equation remains invariant in the transformation:

$$\Psi \rightarrow \Psi' = e^{\mathrm{i}g\alpha}\Psi \qquad (11.5.143)$$

It is therefore obvious that Schrödinger's equation:

$$H\Psi = \mathrm{i}\hbar\frac{\partial}{\partial t}\Psi \qquad (11.5.144)$$

is no longer invariant. Indeed, we quickly see that just the operator $\vec{\nabla}^2$ in the Hamiltonian will pose problem by making appear annoying terms that will not cancel out:

$$\begin{aligned}
&\vec{\nabla}\Psi = e^{-\mathrm{i}g\alpha}\left(\vec{\nabla}\Psi'\right) - \mathrm{i}ge^{-\mathrm{i}g\alpha}\left(\vec{\nabla}\alpha\right)\Psi' \\
&\vec{\nabla}^2\Psi = \vec{\nabla}\left(e^{-\mathrm{i}g\alpha}\left(\vec{\nabla}\Psi'\right)\right) - \mathrm{i}g\vec{\nabla}\left(e^{-\mathrm{i}g\alpha}\left(\vec{\nabla}\alpha\right)\Psi'\right) \\
&= \left[e^{-\mathrm{i}g\alpha}\left(\vec{\nabla}^2\Psi'\right) - \mathrm{i}ge^{-\mathrm{i}g\alpha}\left(\vec{\nabla}\alpha\right)\left(\vec{\nabla}\Psi'\right)\right] - \mathrm{i}g\left[(-\mathrm{i}g)e^{-\mathrm{i}g\alpha}\left(\vec{\nabla}\alpha\right)\Psi' + e^{-\mathrm{i}g\alpha}\vec{\nabla}^2\alpha\Psi' + e^{-\mathrm{i}g\alpha}\vec{\nabla}\alpha\vec{\nabla}\Psi'\right] \\
&\ldots
\end{aligned} \qquad (11.5.145)$$

To solve this problem, we introduce the force field associated with the vector potential and the electrical potential and we will see that it guarantees the local invariance (therefore it is impossible to envisage an invariant phase change without the presence of a force field of this type). The local invariance imposes that the particle is no longer free (there are therefore no free charged particles!).

To do this, let us take again the Hamiltonian of the Pauli equation (see section Relativistic Quantum Physics page 4979):

$$\frac{\left(\vec{p}-q\vec{A}\right)^2}{2m_0} - \frac{\hbar q}{2m_0}\vec{\sigma}\circ\vec{B} + qU \qquad (11.5.146)$$

and let us neglect the interaction between the spin and the magnetic field such that the Hamiltonian becomes:

$$\frac{\left(\vec{p}-q\vec{A}\right)^2}{2m_0} + qU \qquad (11.5.147)$$

Therefore:

$$\frac{\left(-\mathrm{i}\hbar\vec{\nabla}-q\vec{A}\right)^2}{2m_0} + qU \qquad (11.5.148)$$

We thus get the following Schrödinger equation:

$$\left[\frac{\left(-\mathrm{i}\hbar\vec{\nabla}-q\vec{A}\right)^2}{2m_0}+qU\right]\Psi=\mathrm{i}\hbar\frac{\partial}{\partial t}\Psi \tag{11.5.149}$$

What in comparison to the free Schrödinger equation:

$$\frac{\left(-\mathrm{i}\hbar\vec{\nabla}\right)^2}{2m_0}\Psi=\mathrm{i}\hbar\frac{\partial}{\partial t}\Psi \tag{11.5.150}$$

involves the following correspondences (these are operators):

$$\begin{gathered}\vec{\nabla}\rightarrow\vec{D}\equiv\vec{\nabla}-\mathrm{i}\frac{q}{\hbar}\vec{A}\\ \frac{\partial}{\partial t}\rightarrow D^0\equiv\frac{\partial}{\partial t}+\mathrm{i}\frac{q}{\hbar}U\end{gathered} \tag{11.5.151}$$

Let us consider the following gauge transformation (see section Electrodynamics page 4115):

$$\begin{gathered}\vec{A}\rightarrow\vec{A}'=\vec{A}+\vec{\nabla}f\\ U\rightarrow U'=U-\frac{\partial f}{\partial t}\end{gathered} \tag{11.5.152}$$

where $f=f(\vec{r},t)$.

First, we immediately see that the operators are invariant. Indeed, for the first one $\vec{D}$:

$$\begin{aligned}&\left(\vec{\nabla}-\mathrm{i}\frac{q}{\hbar}\vec{A}'\right)e^{\mathrm{i}g\alpha}=\left(\vec{\nabla}-\mathrm{i}\frac{q}{\hbar}\left(\vec{A}+\vec{\nabla}f\right)\right)e^{\mathrm{i}g\alpha}=\left(\vec{\nabla}-\mathrm{i}\frac{q}{\hbar}\vec{A}+\mathrm{i}\frac{q}{\hbar}\vec{\nabla}f\right)e^{\mathrm{i}g\alpha}\\&=\mathrm{i}ge^{\mathrm{i}g\alpha}\left(\vec{\nabla}\alpha\right)+e^{\mathrm{i}g\alpha}\vec{\nabla}-\mathrm{i}\frac{q}{\hbar}\vec{A}e^{\mathrm{i}g\alpha}-\mathrm{i}\frac{q}{\hbar}\vec{\nabla}fe^{\mathrm{i}g\alpha}\\&=e^{\mathrm{i}g\alpha}\left(\mathrm{i}g\vec{\nabla}\alpha+\vec{\nabla}-\mathrm{i}\frac{q}{\hbar}\vec{A}-\mathrm{i}\frac{q}{\hbar}\vec{\nabla}f\right)\end{aligned} \tag{11.5.153}$$

However, if we put g as being $q/\hbar$ and f as α then we have:

$$\left(\vec{\nabla}-\mathrm{i}\frac{q}{\hbar}\vec{A}'\right)e^{\mathrm{i}\frac{q}{\hbar}\alpha}=e^{\mathrm{i}\frac{q}{\hbar}\alpha}\left(\mathrm{i}\cancel{\frac{q}{\hbar}\vec{\nabla}}f+\vec{\nabla}-\mathrm{i}\frac{q}{\hbar}\vec{A}-\mathrm{i}\cancel{\frac{q}{\hbar}\vec{\nabla}}f\right)=e^{\mathrm{i}\frac{q}{\hbar}\alpha}\left(\vec{\nabla}-\mathrm{i}\frac{q}{\hbar}\vec{A}\right) \tag{11.5.154}$$

Thus simply:

$$\left(\vec{\nabla}-\mathrm{i}\frac{q}{\hbar}\vec{A}'\right)e^{\mathrm{i}\frac{q}{\hbar}\alpha}=e^{\mathrm{i}\frac{q}{\hbar}\alpha}\left(\vec{\nabla}-\mathrm{i}\frac{q}{\hbar}\vec{A}\right) \tag{11.5.155}$$

Similarly, knowing now that f is α we have for the operator D^0:

$$\begin{aligned}\left(\frac{\partial}{\partial t}+\mathrm{i}\frac{q}{\hbar}U'\right)e^{\mathrm{i}\frac{q}{\hbar}\alpha}&=\left(\frac{\partial}{\partial t}+\mathrm{i}\frac{q}{\hbar}\left(U-\frac{\partial\alpha}{\partial t}\right)\right)e^{\mathrm{i}\frac{q}{\hbar}\alpha}\\&=\mathrm{i}\frac{q}{\hbar}e^{\mathrm{i}\frac{q}{\hbar}\alpha}\frac{\partial\alpha}{\partial t}+e^{\mathrm{i}\frac{q}{\hbar}\alpha}\frac{\partial}{\partial t}+\mathrm{i}\frac{q}{\hbar}Ue^{\mathrm{i}\frac{q}{\hbar}\alpha}-\mathrm{i}\frac{q}{\hbar}\frac{\partial\alpha}{\partial t}e^{\mathrm{i}\frac{q}{\hbar}\alpha}\\&=e^{\mathrm{i}\frac{q}{\hbar}\alpha}\left(\frac{\partial}{\partial t}+\mathrm{i}\frac{q}{\hbar}U\right)\end{aligned} \tag{11.5.156}$$

Therefore we have:

$$\begin{gathered}\left(\vec{\nabla}-\mathrm{i}\frac{q}{\hbar}\vec{A}'\right)e^{\mathrm{i}\frac{q}{\hbar}\alpha}=e^{\mathrm{i}\frac{q}{\hbar}\alpha}\left(\vec{\nabla}-\mathrm{i}\frac{q}{\hbar}\vec{A}\right)\\ \left(\frac{\partial}{\partial t}+\mathrm{i}\frac{q}{\hbar}U'\right)e^{\mathrm{i}\frac{q}{\hbar}\alpha}=e^{\mathrm{i}\frac{q}{\hbar}\alpha}\left(\frac{\partial}{\partial t}+\mathrm{i}\frac{q}{\hbar}U\right)\end{gathered}\tag{11.5.157}$$

Thus:

$$\begin{gathered}\vec{D}'e^{\mathrm{i}\frac{q}{\hbar}\alpha}=e^{\mathrm{i}\frac{q}{\hbar}\alpha}\vec{D}\\ \left(D^{0\prime}\right)e^{\mathrm{i}\frac{q}{\hbar}\alpha}=e^{\mathrm{i}\frac{q}{\hbar}\alpha}\left(D^{0}\right)\end{gathered}\tag{11.5.158}$$

The relation:

$$\frac{\left(-\mathrm{i}\hbar\vec{\nabla}\right)^2}{2m}\Psi=\mathrm{i}\hbar\frac{\partial}{\partial t}\Psi\tag{11.5.159}$$

Becomes then with the new correspondences:

$$\frac{\left(-\mathrm{i}\hbar\vec{D}\right)^2}{2m}\Psi=\mathrm{i}\hbar D^0\Psi\tag{11.5.160}$$

and with the previous developments, we have:

$$e^{\mathrm{i}g\alpha}\frac{\left(-\mathrm{i}\hbar\vec{D}\right)^2}{2m}\Psi=\frac{\left(-\mathrm{i}\hbar\vec{D}'\right)^2}{2m}e^{\mathrm{i}g\alpha}\Psi\tag{11.5.161}$$

Or written differently:

$$e^{\mathrm{i}g\alpha}\mathrm{i}\hbar D^0\Psi=\mathrm{i}\hbar D^{0\prime}e^{\mathrm{i}g\alpha}\Psi\tag{11.5.162}$$

Thus:

$$\frac{\left(-\mathrm{i}\hbar\vec{D}'\right)^2}{2m}e^{\mathrm{i}g\alpha}\Psi=\mathrm{i}\hbar D^{0\prime}e^{\mathrm{i}g\alpha}\Psi\tag{11.5.163}$$

Which gives after simplification:

$$\frac{\left(-\mathrm{i}\hbar\vec{D}'\right)^2}{2m}\Psi=\mathrm{i}\hbar D^{0\prime}\Psi\tag{11.5.164}$$

Thus, by requesting the local gauge invariance, we have make appear an interaction ... and we know well which interaction it is!

The Schrödinger equation of a particle moving in an electromagnetic field is therefore invariant under the local phase transformation. The phase of a wave function is indeed a new local variable in the Weyl sense and the electromagnetic potential can be interpreted, according to Weyl, as a connection binding the phases to different points.

We conclude that the electromagnetic field is a consequence of the local gauge invariance based on the group $\mathrm{U}(1)$, a group of one-dimensional unitary matrices (see section Set Algebra page

1424). The interest is to build Gauge theories on more complicated (non-abelian) groups: these theories are named "Yang-Mills theories".

So we can make an analogy: If a global gauge is like to turn all the hands of a watch of a constant angle around the circle, the local gauge is similar as if we make this angle vary continuously from one point to another of space-time. One might think that such an upheaval of the hands of a watch generate tensions and compressions on the springs, sign of a modification of the electromagnetic field at each point!? But not at all: all the springs remain at rest, as if the electromagnetic field automatically adjusted to compensate for these local deformations:

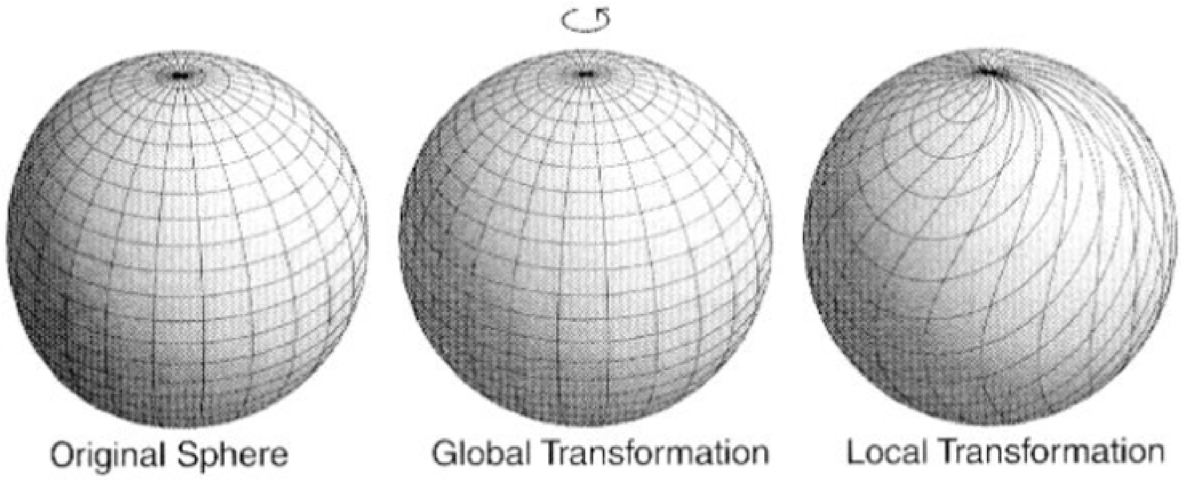


Figure 11.149: Global and local gauge illustration concept (source: ?)

Now let us go a little further but without going too deep (as this textbook is only about Elementary Applied Mathematics)... We showed earlier above that the Lagrangian of the free Dirac equation was:

$$L=\bar{\Psi}\left(\mathrm{i}\gamma^{\mu}\partial_{\mu}-m_0\right)\Psi \qquad (11.5.165)$$

Now, since this Lagrangian does not reveal the electromagnetic field, we strongly suspect that it does not carry in it a local Gauge invariance...

Therefore the operator ∂_{μ} has somewhere a lack... But, the equivalent of the divergence operator $\vec{\nabla}$ in the free Schrödinger equation is here the covariant derivative ∂_{μ}. So in the same way that we have associated the following operators to guarantee the local Gauge invariance of the free Schrödinger equation:

$$\begin{gathered}\vec{\nabla}\rightarrow\vec{D}\equiv\vec{\nabla}-\mathrm{i}\frac{q}{\hbar}\vec{A}\\ \frac{\partial}{\partial t}\rightarrow D^0\equiv\frac{\partial}{\partial t}+\mathrm{i}\frac{q}{\hbar}U\end{gathered} \qquad (11.5.166)$$

It is tempting to combine the whole into a new operator called the "covariant derivative":

$$D_{\mu}\equiv\partial_{\mu}-\mathrm{i}\frac{q}{\hbar}A_{\mu} \qquad (11.5.167)$$

with:

$$D_0\equiv\partial_0+\mathrm{i}\frac{q}{\hbar}A_0=\frac{\partial}{c\partial t}+\mathrm{i}\frac{q}{\hbar}(-U) \qquad (11.5.168)$$

The Lagrangian of the free Dirac equation would then be written:

$$L=\bar{\Psi}\left(\mathrm{i}\gamma^{\mu}D_{\mu}-m_0\right)\Psi \tag{11.5.169}$$

or in Feynman notation:

$$L=\bar{\Psi}\left(\mathrm{i}\not{D}-m_0\right)\Psi \tag{11.5.170}$$

Therefore:

$$\begin{aligned}L&=\bar{\Psi}\left(\mathrm{i}\gamma^{\mu}\left(\partial_{\mu}-\mathrm{i}\frac{q}{\hbar}A_{\mu}\right)-m_0\right)\Psi=\bar{\Psi}\left(\mathrm{i}\gamma^{\mu}\partial_{\mu}-m_0\right)\Psi-\bar{\Psi}\mathrm{i}\gamma^{\mu}\mathrm{i}\frac{q}{\hbar}A_{\mu}\Psi\\&=\bar{\Psi}\left(\mathrm{i}\gamma^{\mu}\partial_{\mu}-m_0\right)\Psi+\bar{\Psi}\gamma^{\mu}\Psi\frac{q}{\hbar}A_{\mu}=\bar{\Psi}\left(\mathrm{i}\gamma^{\mu}\partial_{\mu}-m_0\right)\Psi-j^{\mu}A_{\mu}\end{aligned} \tag{11.5.171}$$

with:

$$\boxed{j^{\mu}=-\frac{q}{\hbar}\bar{\Psi}\gamma^{\mu}\Psi} \tag{11.5.172}$$

It only remains to add the term of the field to obtain the total Lagrangian of the Dirac equation (it would have been relatively hard to find it in another way ...):

$$\boxed{L_D=\bar{\Psi}\left(\mathrm{i}\gamma^{\mu}\partial_{\mu}-m_0\right)\Psi-j^{\mu}A_{\mu}+\frac{1}{4}\mu_0F_{\mu\nu}F^{\mu\nu}} \tag{11.5.173}$$

which corresponds to the "Dirac-Maxwell equations" and which is the "Quantum electrodynamic Lagrangian" (in natural units) where on the left we have the term of the fermions and on the right the interaction part of the bosons of zero mass (photons).

Thus the fact of having added to the free Lagrangian a condition of invariance by local transformations, has led us to a theory with interaction that we can write with more rigour and in developed form:

$$\mathcal{L}_{\text{QED}}=\bar{\Psi}\left(\mathrm{i}\gamma^{\mu}\partial_{\mu}-m_0\right)\Psi+\frac{q}{\hbar}\bar{\Psi}\gamma^{\mu}\Psi A_{\mu}+\frac{1}{4}\mu_0F_{\mu\nu}F^{\mu\nu} \tag{11.5.174}$$

Or in natural units and with the charge of the electron:

$$\mathcal{L}_{\text{QED}}=\bar{\Psi}\left(\mathrm{i}\gamma^{\mu}\partial_{\mu}-m_0\right)\Psi+q\bar{\Psi}\gamma^{\mu}\Psi A_{\mu}+\frac{1}{4}F_{\mu\nu}F^{\mu\nu} \tag{11.5.175}$$

However, quantum electrodynamics was lacking in the 11940s (holocene calendar) to describe a large number of particles that were detected by accelerators. Certainly, in a way, it has been extended to describe new particles. But many of them seemed to enjoy properties that quantum electrodynamics could not account for.

In fact, the reason is simple ... it is a theory in which no exact solution is known so far, a situation that persists until the day these lines are written (12008 according to holocene calendar). The only available calculation method is named "perturbative development". The idea is essentially the same as that of limited development practised in the field of differential calculus. In this case, if we do not know how to calculate the value of a function, we decompose it into a sequence of polynomials and the approximation is refined as we take into account terms of higher order. Such a series development begins with a zero order term, which is just the value of the unknown function at a certain point where we know how to calculate this function.

In the case of the perturbative development of quantum electrodynamics, the zero order term represents pure propagation without interaction (the intensity of the interaction between the electron and the magnetic field is set to zero). In this approximation, quantum electrodynamics is a theory of free particles and it is exactly calculable. We have electrons, positrons and photons but they cross without influencing each other. The next term in the series development, that of the first order, is also exactly calculable. In this approximation, the theory seems to reflect the real world fairly accurately. Very interesting physical phenomena appear in this first-order approximation of the real theory of photon-electron interaction and the theory agrees well with the experimental results.

Unfortunately, it soon became apparent that the calculation of second-order terms and higher terms seemed meaningless as they yielded infinite values... today there still exist only approximate methods of resolution and that are not completely satisfactory. Since then physicists have been obliged to look for another technique of approximation based on a renormalization of the equations... and the results are extraordinarily good (to the 11th decimal!) but in the facts it looks like a bit like do-it-yourself physics...

Remark

Quantum electrodynamics also suffer from a perceived lack of aesthetic appeal. The theory give rise to infinities that had to be removed by provisional methods introduced for no reason other than to give useful results. It is a pragmatic approach that Dirac didn't like at all: « *Recent work by Lamb, Schwinger, Feynman and others has been very successful... but the resulting theory is an ugly and incomplete one and cannot be considered as a satisfactory solution of the problem of the electron.* » When asked for his opinion about the recent developments in quantum electrodynamics, Dirac said, « *I might have thought that the new ideas were correct if they had not been so ugly.* »

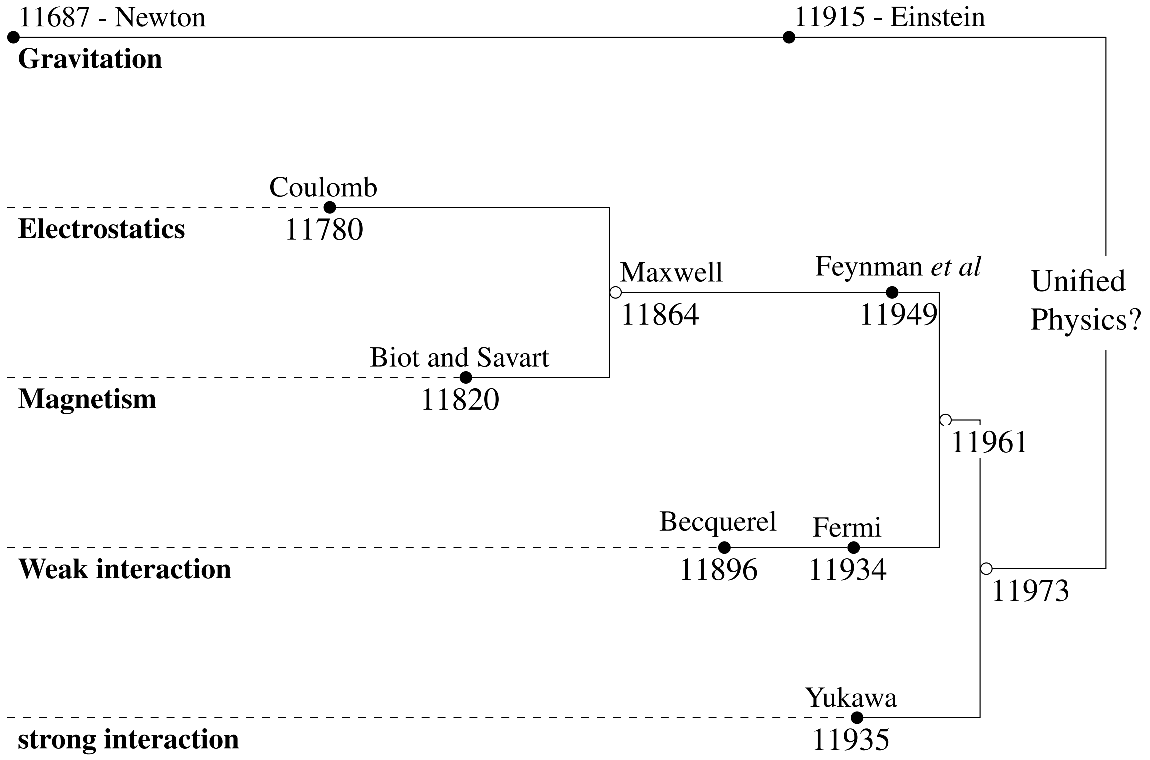
11.6. Elementary Particle Physics

We have already mentioned in the section of Nuclear Physics that we experiment that the radioactive nuclei does not emit neutrons or protons (i.e. its single constituents). But we can ask ourselves: How do it synthesize an alpha particle, or transform a proton into a neutron or vice versa? To answer these questions, let us examine the forces in presence!

Before the discovery of radioactivity, physicists had identified two fundamental forces: the gravitational force[42] and the electromagnetic force. The discovery of radioactivity and studies on the atomic nucleus led physicists to introduce not one but two new fundamental forces! In the figure below, the years are given according to the holocene calendar:



11687 - Newton
11915 - Einstein
Gravitation
Coulomb
Electrostatics
11780
Maxwell
11864
Feynman *et al*
11949
Unified Physics?
Biot and Savart
Magnetism
11820
11961
Becquerel
Fermi
Weak interaction
11896
11934
11973
Yukawa
strong interaction
11935

Figure 11.150: **Interactions discoveries (source: `http://femto-physique.fr`, author: Jimmy Roussel)**

Even before knowing the exact composition of the nuclei, to explain the existence of these tiny systems and wearing sometimes strong positive charges, physicists had foreseen the need for a powerful cohesive force capable of dominating the electrostatic repulsion exerted between these charges (remember that we saw in the section of Classical Mechanics that the gravitational force between two bodies of equivalent masses to those of particles is completely negligible). Since the nucleus is small, this "nuclear force" had to have influence at very short distances. When J.

---

[42] We will see it during our study of General Relativity that the gravitational force is fictional and we should us the expression "gravitational interaction" instead.

Chadwick discovered the neutron, it was shown experimentally that attractive force is also well practised between two neutrons, two protons and between a neutron and a proton. In 11935 (holocene calendar), Hideki Yukawa elaborated a theory about the nuclear force whose outlines seems to be still accepted, but must still be improved following some issues that have been identified (see section Quantum Field Theory page 5158).

However, as we already know, this nuclear force does not explain the transformation of a proton into a neutron, which takes place in the beta radioactivity. It was necessary to introduce a fourth fundamental force, of lower intensity, named for this reason "weak interaction", the nuclear force becomes ipso facto the "strong interaction".

Thus, in principle, radioactivity involves the four fundamental forces of nature: gravity and the electromagnetic force, as alpha and beta particles have mass and charge, and the two nuclear forces, strong and weak (in fact, the gravitation, of lesser intensity than the other three is often neglected at sub-atomic scales).

We partially addressed in the section of Quantum Field Theory (see page 5158) the fundamental interactions and their interactions vectors. Let's do some reminders:

1. We have proved in the section of Special Relativity (see page 5627) that there are two types of particles: those with a mass and will never go at the speed of light (because it will required an infinite energy to get them at this velocity) and those which have zero mass and which are therefore necessarily at the speed of light.

2. We proved in the section of Quantum Field Theory that more a particle has energy, that more (following the Heisenberg's uncertainty principles) it may have long virtual life time and travel considerable distances. We distinguish therefore the interaction that have infinite range of interaction whose particles have no mass and a the interactions that have finite range whose interaction particles have a mass.

Before starting with some arduous calculations, it is desirable first to acquire a vocabulary that is common use among theoretical physicists.

The easiest concept to be addressed in the field of elementary particle physics is the comparison of the four elemental forces via their respective coupling constant (that is something that physicists like to do...).

Remark

Particle physics research has significantly contributed to civil applications across various fields, including medical imaging and treatment with technologies like MRI and proton therapy, radiation detectors for security and environmental monitoring, and material science advancements through synchrotron light sources. It has also revolutionized global communication with the invention of the World Wide Web at CERN and supported innovations in renewable energy and environmental tools. These breakthroughs showcase how fundamental research drives practical innovations that benefit society.

Before we tackle with the various topics we have seen that some people are misleaded by the treatment of certain particles in modern physics as being "pointlike" (i.e. dimensionless). So first thing... "pointlike" is a misleading terminology (like "Big Bang" and many others in physics!) - it just means a quantum particle not made of more fundamental quantum particles. Second, treating particles like pointlike is similar as in astronomy where we often treat planets as pointlike because the scales involved in a given case authorize us such an acceptable approximation (even really big objects such as stars are pointlike particles when viewed from far enough away).

11.6.1 Coupling Constants

We will try here to rank the four forces according to their intensity through the use of "coupling constants".

> Caution!!!! All couplings in Quantum Field Theory are running (with scale), and are not constants (like the fine structure constant or the Hubble constant in Cosmology...!), but are named such for historical reasons. Even the electromagnetic coupling runs, and its "constant value" is taken to be the infrared (long distance) value computed and fit. The strong gauge coupling α_s varies by a factor of two between 10 and $1,000$ [GeV].

To do this, we need to calculate the four interactions for two same particles, for example two protons at identical distances, so of nuclear type and compare them to a common value of the units so that their ratio provides a dimensionless number.

This common value will be chosen as the product:

$$\frac{h}{2\pi}c=\hbar c\cong 3.16\cdot 10^{-26}\,[\text{N}\cdot\text{m}^2] \tag{11.6.1}$$

Thus we find:

1. For the gravitational "force" (see section Astronomy page 5255) where:

   $$Fr^2=GmM\,[\text{N}\cdot\text{m}^2] \tag{11.6.2}$$

   with the proton mass such that $m=M\cong 1.67\cdot 10^{-27}$ [kg], the coupling constant of the gravitational force is therefore by definition:

   $$\alpha_G=\frac{GMm}{\hbar c}=\frac{Gm_p^2}{\hbar c}\cong 6\cdot 10^{-39} \tag{11.6.3}$$

2. For the electrical force (see section Electrostatics page 3968) where:

   $$Fr^2=\frac{1}{4\pi\varepsilon_0}qQ\,[\text{N}\cdot\text{m}^2] \tag{11.6.4}$$

   with the proton charge such that $q=Q\cong 1.602\cdot 10^{-19}$ [C], the coupling constant of the electric force is therefore by definition:

   $$\alpha=\frac{\dfrac{1}{4\pi\varepsilon_0}qQ}{\hbar c}\cong\frac{1}{137} \tag{11.6.5}$$

Remark

Here we fall back on the "fine-structure constant" that we had already seen in the section of Corpuscular Quantum Physics. We therefore better understand the start choice for the relative comparison of interactions.

3. For the strong nuclear force, where F represents the "strong nuclear charge", the strong coupling constant has for value (caution! the value depends on the chosen theoretical model!):

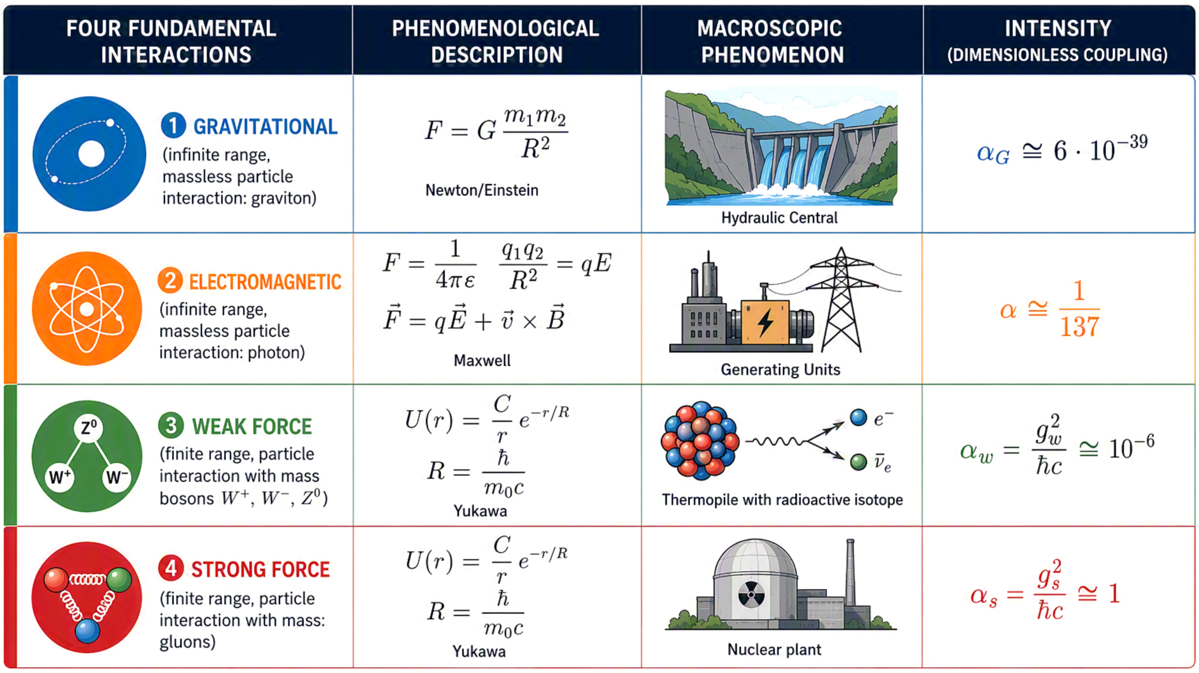
$$\alpha_s=\frac{F\cdot F}{\hbar c}=\frac{g_s^2}{\hbar c}\cong 1 \tag{11.6.6}$$

hence its name.

4. For the weak nuclear force responsible for the decay of particles, f represents the "weak nuclear charge", and its weak coupling constant value is then (caution! the value depends on the chosen theoretical model!):

$$\alpha_w=\frac{f\cdot f}{\hbar c}=\frac{g_w^2}{\hbar c}\cong 10^{-6} \tag{11.6.7}$$

So all this can be summarized in the following phenomenological table:



FOUR FUNDAMENTAL INTERACTIONS	PHENOMENOLOGICAL DESCRIPTION	MACROSCOPIC PHENOMENON	INTENSITY (DIMENSIONLESS COUPLING)
① **GRAVITATIONAL** (infinite range, massless particle interaction: graviton)	$F=G\dfrac{m_1m_2}{R^2}$ Newton/Einstein	Hydraulic Central	$\alpha_G\cong 6\cdot 10^{-39}$
② **ELECTROMAGNETIC** (infinite range, massless particle interaction: photon)	$F=\dfrac{1}{4\pi\varepsilon}\dfrac{q_1q_2}{R^2}=qE$ $\vec{F}=q\vec{E}+\vec{v}\times\vec{B}$ Maxwell	Generating Units	$\alpha\cong\dfrac{1}{137}$
③ **WEAK FORCE** (finite range, particle interaction with mass bosons W^+, W^-, Z^0)	$U(r)=\dfrac{C}{r}e^{-r/R}$ $R=\dfrac{\hbar}{m_0c}$ Yukawa	e^- $\bar{\nu}_e$ Thermopile with radioactive isotope	$\alpha_w=\dfrac{g_w^2}{\hbar c}\cong 10^{-6}$
④ **STRONG FORCE** (finite range, particle interaction with mass: gluons)	$U(r)=\dfrac{C}{r}e^{-r/R}$ $R=\dfrac{\hbar}{m_0c}$ Yukawa	Nuclear plant	$\alpha_s=\dfrac{g_s^2}{\hbar c}\cong 1$

Figure 11.151: **Phenomenological table of the 4 fundamental interactions**

Caution!!! There is no principle of physics yet (in the beginning of the 121st century according to holocene calendar) that says physicals laws or constants have to be the same everywhere and always. Indeed, the reader must remember that the "laws" of physics are **descriptive**, not **imperative** and therefore they are some observed regularity in what we can observe experimentally with sufficiently wide occurrence or relevance! Asking whether the laws can change is no more and no less than asking whether regularities which have been observed up till now might not be quite as universal as was thought. The answer to that is: YES! This could drive the reader a bit mad. Indeed, how can we possibly do Science if the rules keep changing? But if you are a professional active scientist, you have to face up to that possibility - and you have a responsibility to check out if there is evidence beyond reasonable doubt about it! We will repeat this warning multiple times in this textbook as its seems that this is something necessary!

Or also with the following diagram (more interesting) where we can see, taking into account the results we have found during our study of the massic fields and non-massic fields in the context of the Yukawa model (see section Quantum Field Theory page 5164):

1. In ordinate the intensity of the forces as previously calculated according to the distance as given by the Yukawa model of massic fields (weak and strong interactions) and non-massic fields (electromagnetic and gravitational interactions).
2. The representative interaction patterns (Feynman diagrams) in accordance with the results obtained and particles already mentioned in the section of Quantum Field Theory.

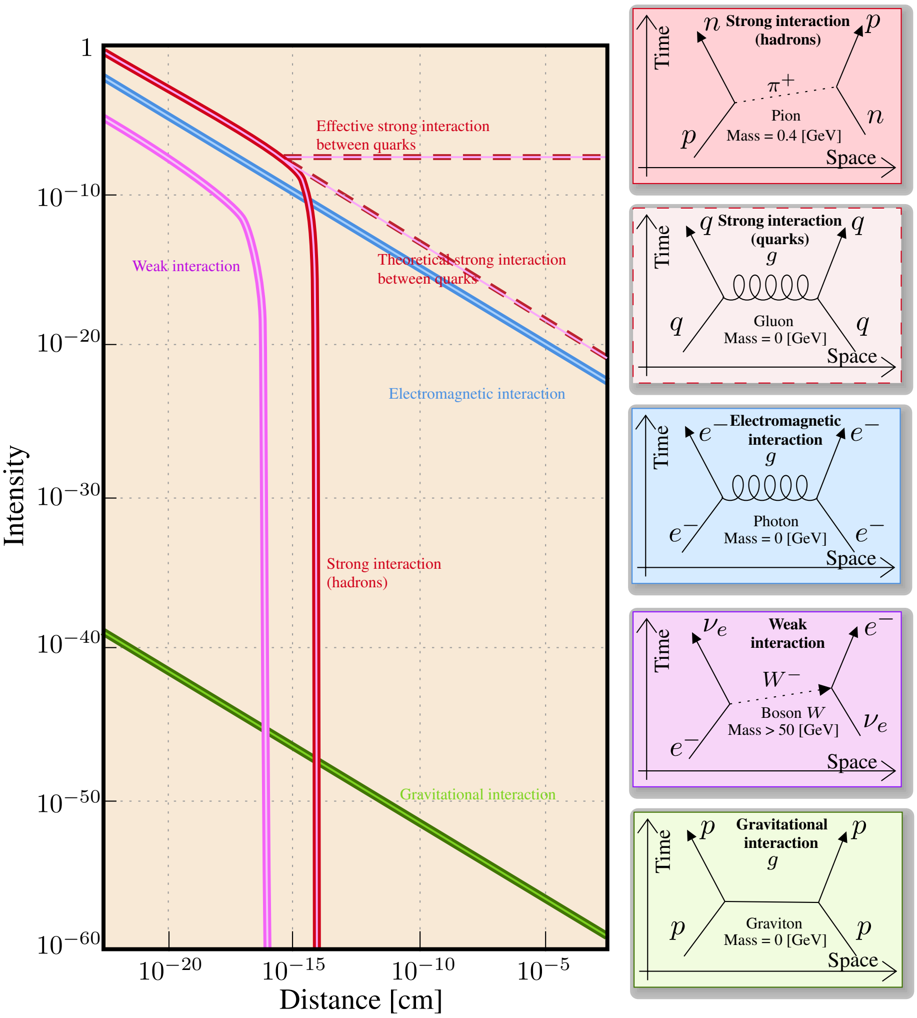


Figure 11.152: **Feynman diagrams and interaction distance of the fundamental forces**

In most physics textbooks you will read that gravity is the weakest of all forces, many orders of magnitude weaker than electromagnetism. This is wrong! Recall that the gravitational force is fictional, like the centrifugal (fictional) force. No one compares the value of centrifugal (fictional) force with other forces. Its value depends on the circumstances! So it is with gravity. The gravitational force depends on the masses and charges of the particles. Most textbooks just take a special case (an electron and a proton most of the time) and make from it a stupid generalization. It is not the relative strength of the gravitational and electrical forces in all cases. In fact, there is no universal way we can describe the strength of the gravitational force!

Figure 11.155: Splitting particles/antiparticles by electric charge (quarks and gluons as shown as different color states) (credit: Izaak Neutelings)

As already mentioned in the section of Nuclear Physics, not only nucleus of atoms decays! But also most particles and even some fundamental particles (yes! but they are not made of the stuff they decay of as experience show us but with the τ fundamental particle that has at least 30 different decay chains[43]). However some particles don't decay (as far as we know) like: the photon, the electron (anti-electron), the lightest neutrino (and its anti-particle) and (presumed) the graviton. The reader can refer to the *Review of Particle Physics: particle data groups* (see [526]) that contains more than a hundred pages of fundamental particles properties with for each a huge list of disintegrations paths.

Type	Name	Symbol	Energy [MeV]	Mean lifetime
Lepton	Electron / Positron	e^-/e^+	0.511	$>6.6\cdot 10^{28}$ years
	Muon / Antimuon	μ^-/μ^+	105.7	$2.2\cdot 10^{-6}$ seconds
	Tau lepton / Antitau	τ^-/τ^+	$1,777$	$2.9\cdot 10^{-13}$ seconds
Meson	Neutral Pion	π^0	135	$8.4\cdot 10^{-17}$ seconds
	Charged Pion	π^+/pi^-	139.6	$2.6\cdot 10^{-8}$ seconds
Baryon	Proton / Antiproton	p^+/p^-	938.2	$>10^{29}$ years
	Neutron / Antineutron	$n/\bar{n}$	939.6	885.7 seconds
Boson	W boson	W^+/W^-	$80,377$	10^{-25} seconds
	Boson	W^+/W^-	$80,377$	10^{-25} seconds
	Photon	γ	$-$	$+\infty$

Table 11.23: Some "fundamental" particles mean lifetime and mass

Remark

The electron is a charge lepton and leptons can decay to other leptons, but in standard conditions not the electron since the other two charge leptons are heavier. However, if we accelerate the electron in high velocities (energies actually not reachable with accelerators like the LHC in the early 121st century according to holocene calendar but energies level that were existing during the first instant of the Big Bang) then we now talk about its electroweak field. Since W bosons have zero average rest mass under an electroweak field it is possible for an electron to decay to a W^- and an electron neutron ν_e.

It should be specified for the general knowledge of the reader that these four forces are described by respectively four theories:

1. General Relativity (includes Classical Mechanics) for gravitation.
2. Quantum Electrodynamics (includes Electrodynamics) for the electromagnetic force.
3. Electroweak Theory (which includes Quantum Electrodynamics) for the weak interaction.
4. Quantum Chromodynamics for the strong interaction.

The last three are grouped in the "Standard Model".

Here is another figure summarizing the state of the art knowledge of particles in the early 121st (holocene calendar):

---

[43] Like $\tau\to e^-\bar{\nu}_e\nu_\tau$ (17.83% of the time) or $\tau\to\mu^-\bar{\nu}_\mu\nu_\tau$ (17.41% of the time) or $\tau\to\pi^-\nu_\tau$ (10.83% of the time) or $\tau\to\pi^-\pi^0\nu_\tau$ (25.52% of the time), etc.

t'
top-prime

Six flavors (u, d, s, c, b, t) and their hypothetical extensions (b', t') form hadrons.

1.2 LEPTONS: LIGHT AND COLORLESS

		e^-	μ^-	τ^-
CHARGED ($Q=-1$)	Name	electron	muon	tau
	Mass (approx.)	0.511 MeV/c^2	105.66 MeV/c^2	1.776 GeV/c^2
	Magnetic dipole μ $[e\cdot\hbar/2m_e]$	−1.001 159 652 181(28)	−1.001 165 920(7)	−1.001 177 21(5)
NEUTRINOS ($Q=0$)		ν_e	ν_μ	ν_τ
	Name	electron neutrino	muon neutrino	tau neutrino
	Mass (approx.)	< 0.8 eV/c^2	< 0.17 MeV/c^2	< 18.2 MeV/c^2
	Magnetic dipole μ $[e\cdot\hbar/2m_e]$	$< 2.9\times10^{-11}$	$< 1.8\times10^{-10}$	$< 1.5\times10^{-10}$

The family including the electron, the muon and the tau, as well as their respective neutrinos.

1.3 GAUGE BOSONS AND THE HIGGS BOSON

γ **Photon**
Electromagnetic force

g **Gluon**
Strong force
(interaction of quarks)

$W^{+,-}, Z^0$ **Bosons**
Weak force
(weak interaction)

H **Higgs boson**
Higgs field
(origin of mass)

G **Graviton (hypothetical)**
Gravitational force
(hypothetical)

Particle	Charge Q/e	Mass (approx.)	Magnetic dipole μ $[e\cdot\hbar/2m_p]$
γ	0	0	0
g	0	0	0
W^+	+1	80.4 GeV/c^2	+1.93
W^-	−1	80.4 GeV/c^2	−1.93
Z^0	0	91.2 GeV/c^2	0
H	0	125.2 GeV/c^2	0
G	0	0	0

Force carriers (γ, g, W, Z, graviton) and the Higgs boson, origin of mass.

2. COMPOSITE PARTICLES (THE UNIVERSE OF HADRONS)

This structure extends to composite particles such as hadrons and explores frontiers beyond the established model.

2.1 BARYONS: QUARK TRIPLETS

p Proton

Charge Q/e	+1
Mass (approx.)	938.27 MeV/c^2
Magnetic dipole μ $[e\cdot\hbar/2m_p]$	+2.793

n Neutron

Charge Q/e	0
Mass (approx.)	939.57 MeV/c^2
Magnetic dipole μ $[e\cdot\hbar/2m_p]$	−1.913

Λ_b Lambda-b

Charge Q/e	0
Mass (approx.)	5619.6 MeV/c^2
Magnetic dipole μ $[e\cdot\hbar/2m_p]$	−0.16 ± 0.05

Ξ^- Xi-minus

Charge Q/e	−1
Mass (approx.)	1321.71 MeV/c^2
Magnetic dipole μ $[e\cdot\hbar/2m_p]$	−0.6507

Composed particles of three quarks, such as the proton (p), the neutron (n) or the baryons Λ_b and Ξ^-.

2.2 MESONS: QUARK–ANTIQUARK PAIRS

π^+ (pion)

Charge Q/e	+1
Mass (approx.)	139.57 MeV/c^2
Magnetic dipole μ $[e\cdot\hbar/2m_p]$	+0.51

K^+ (kaon)

Charge Q/e	+1
Mass (approx.)	493.68 MeV/c^2
Magnetic dipole μ $[e\cdot\hbar/2m_p]$	+0.31

J/ψ (charmonium)

Charge Q/e	0
Mass (approx.)	3096.9 MeV/c^2
Magnetic dipole μ $[e\cdot\hbar/2m_p]$	0

Υ (upsilon)

Charge Q/e	0
Mass (approx.)	9460.3 MeV/c^2
Magnetic dipole μ $[e\cdot\hbar/2m_p]$	0

Ephemeral particles such as the pion (π), the kaon (K) or the heavy quarkonium states J/ψ and Υ.

3. BEYOND THE STANDARD MODEL: AXIONS AND DARK MATTER

Axion

Charge Q/e	0
Mass (approx.)	$10^{-6}-10^{-3}$ eV/c^2 *
Magnetic dipole μ $[e\cdot\hbar/2m_e]$	≈ 0

Dark Matter

Charge Q/e	0
Mass (approx.)	GeV – TeV **
Magnetic dipole μ $[e\cdot\hbar/2m_e]$	Unknown

Search for very light hypothetical particles (axions) to explain cosmic mysteries.

●	FERMIONS (matter)
⬡	HADRONS (composite)
∿	BOSONS (force carriers)
—	STRONG BOND (between quarks)
- - -	HYPOTHETICAL EXTENSIONS

* Typical QCD axion mass range (model dependent).

** Typical mass range for dark matter candidates (model dependent).

Values are approximate and model dependent.

11.6.2 Spin magnetic resonance

We have hesitated to treat the subject of spin resonance in this section but after reflection, it's not nuclear physics because the calculations does not apply only well to the nucleus of atoms and this is not really pure relativistic quantum physics because it does not only apply well to elementary particles like electrons (as assumed in our developments in the section of Relativistic Quantum Physics).

During our proof of the Pauli equation in the section of Relativistic Quantum Physics using physicist art of life... we saw that for a particle of spin $^1/_2$ (which could be a nuclear nucleus of spin $^1/_2$), we had:

$$\mathrm{i}\hbar\frac{\partial}{\partial t}\phi_{a0}\cong\left[\frac{\|\vec{p}\|^2}{2m_0}-\frac{q\vec{B}\circ\vec{L}}{2m_0}-\frac{\hbar q}{2m_0}\vec{\sigma}\circ\vec{B}+qU\right]\phi_{a0} \tag{11.6.8}$$

where there is therefore a term relatively to the spin in the Hamiltonian, that is:

$$H_S=-\frac{\hbar q}{2m}\vec{\sigma}\circ\vec{B}=-\mu\vec{\sigma}\circ\vec{B}=-\frac{2}{2}\mu\vec{\sigma}\circ\vec{B}=-\frac{g\mu}{2}\vec{\sigma}\circ\vec{B} \tag{11.6.9}$$

By putting:

$$g=2 \tag{11.6.10}$$

Being for reminder the "Lande factor" or "gyromagnetic factor" (see section Relativistic Quantum Physics page 4985).

Now let us dive the particle that will be named "probe" in a stable oscillating magnetic field following a horizontal plane and constant on the vertical plane of the type:

$$\vec{B}=\begin{pmatrix}B_A\cos(\omega t)\\-B_A\sin(\omega t)\\B_0\end{pmatrix} \tag{11.6.11}$$

where in practice the field B_0 goes form 0.1 to 17 Teslas.

Therefore it comes:

$$\begin{aligned}H_S&=-\frac{g\mu}{2}\vec{\sigma}\circ\vec{B}=-\frac{g\mu}{2}\begin{pmatrix}\sigma_1\\\sigma_2\\\sigma_3\end{pmatrix}\circ\begin{pmatrix}B_A\cos(\omega t)\\-B_A\sin(\omega t)\\B_0\end{pmatrix}\\&=-\frac{g\mu}{2}\left(\sigma_1B_A\cos(\omega t)-\sigma_2B_A\sin(\omega t)+\sigma_3B_0\right)\\&=-\frac{g\mu}{2}\left(\begin{bmatrix}0&1\\1&0\end{bmatrix}B_A\cos(\omega t)-\begin{bmatrix}0&-\mathrm{i}\\\mathrm{i}&0\end{bmatrix}B_A\sin(\omega t)+\begin{bmatrix}1&0\\0&-1\end{bmatrix}B_0\right)\\&=-\frac{g\mu}{2}\left(\begin{bmatrix}0&B_A\cos(\omega t)\\B_A\cos(\omega t)&0\end{bmatrix}-\begin{bmatrix}0&-\mathrm{i}B_A\sin(\omega t)\\\mathrm{i}B_A\sin(\omega t)&0\end{bmatrix}+\begin{bmatrix}B_0&0\\0&-B_0\end{bmatrix}\right)\\&=-\frac{g\mu}{2}\begin{bmatrix}B_0&B_A\cos(\omega t)+\mathrm{i}B_A\sin(\omega t)\\B_A\cos(\omega t)-\mathrm{i}B_A\sin(\omega t)&-B_0\end{bmatrix}\\&=-\frac{g\mu}{2}\begin{bmatrix}B_0&B_Ae^{\mathrm{i}\omega t}\\B_Ae^{-\mathrm{i}\omega t}&-B_0\end{bmatrix}\end{aligned} \tag{11.6.12}$$

We then have by focusing only on this Hamiltonian:

$$\mathrm{i}\hbar\frac{\partial}{\partial t}\phi_{a0}=-\frac{g\mu}{2}\begin{bmatrix}B_0 & B_Ae^{\mathrm{i}\omega t}\\ B_Ae^{-\mathrm{i}\omega t} & -B_0\end{bmatrix}\phi_{a0} \tag{11.6.13}$$

And as ϕ_{a0} is the double component of a spinor, let us write it explicitly:

$$\mathrm{i}\hbar\frac{\partial}{\partial t}\begin{pmatrix}\alpha_+(t)\\ \alpha_-(t)\end{pmatrix}=-\frac{g\mu}{2}\begin{bmatrix}B_0 & B_Ae^{\mathrm{i}\omega t}\\ B_Ae^{-\mathrm{i}\omega t} & -B_0\end{bmatrix}\begin{pmatrix}\alpha_+(t)\\ \alpha_-(t)\end{pmatrix} \tag{11.6.14}$$

Thus after rearrangement:

$$\frac{\partial}{\partial t}\begin{pmatrix}\alpha_+(t)\\ \alpha_-(t)\end{pmatrix}=\frac{\mathrm{i}}{2}\begin{bmatrix}\dfrac{g\mu}{\hbar}B_0 & \dfrac{g\mu}{\hbar}B_Ae^{\mathrm{i}\omega t}\\ \dfrac{g\mu}{\hbar}B_Ae^{-\mathrm{i}\omega t} & -\dfrac{g\mu}{\hbar}B_0\end{bmatrix}\begin{pmatrix}\alpha_+(t)\\ \alpha_-(t)\end{pmatrix} \tag{11.6.15}$$

And let us recall that we proved at the very end of the section of Relativistic Quantum Physics that:

$$\omega=-g\gamma B=-\frac{g\mu_BB}{\hbar} \tag{11.6.16}$$

It comes then naturally to write:

$$\omega_0=-g\gamma B=-\frac{g\mu_BB_0}{\hbar} \tag{11.6.17}$$

$$\omega_A=-g\gamma B=-\frac{g\mu_BB_A}{\hbar} \tag{11.6.18}$$

This gives us:

$$2\begin{pmatrix}\dot{\alpha}_+(t)\\ \dot{\alpha}_-(t)\end{pmatrix}=\mathrm{i}\begin{bmatrix}\omega_0 & \omega_Ae^{\mathrm{i}\omega t}\\ \omega_Ae^{-\mathrm{i}\omega t} & -\omega_0\end{bmatrix}\begin{pmatrix}\alpha_+(t)\\ \alpha_-(t)\end{pmatrix} \tag{11.6.19}$$

that is to say a system of two partial differential equation:

$$\begin{aligned}2\dot{\alpha}_+(t)&=\mathrm{i}\left(\omega_0\alpha_+(t)+\omega_Ae^{\mathrm{i}\omega t}\alpha_-(t)\right)\\ 2\dot{\alpha}_-(t)&=\mathrm{i}\left(\omega_Ae^{-\mathrm{i}\omega t}\alpha_+(t)-\omega_0\alpha_-(t)\right)\end{aligned} \tag{11.6.20}$$

If we assume that the spinor is orient to the top initially (initial conditions), then:

$$\begin{pmatrix}\alpha_+(0)\\ \alpha_-(0)\end{pmatrix}=\begin{pmatrix}1\\ 0\end{pmatrix} \tag{11.6.21}$$

Now to solve this system of differential equations we will use the laborious trial and error work already done by our predecessors by assuming that the answer is probably of the type:

$$\begin{aligned}\alpha_+(t)&=A_+e^{\mathrm{i}\omega_+t}=|+\rangle\\ \alpha_-(t)&=A_-e^{\mathrm{i}\omega_-t}=|-\rangle\end{aligned} \tag{11.6.22}$$

that is to say... wave functions!!!

So by injecting these solutions in the system of differential equations we get:

$$\begin{aligned}2\frac{\mathrm{d}}{\mathrm{d}t}A_+e^{\mathrm{i}\omega_+t}&=\mathrm{i}\left(\omega_0A_+e^{\mathrm{i}\omega_+t}+\omega_Ae^{\mathrm{i}\omega t}A_-e^{\mathrm{i}\omega_-t}\right)\\2\frac{\mathrm{d}}{\mathrm{d}t}A_-e^{\mathrm{i}\omega_-t}&=\mathrm{i}\left(\omega_Ae^{-\mathrm{i}\omega t}A_+e^{\mathrm{i}\omega_+t}-\omega_0A_-e^{\mathrm{i}\omega_-t}\right)\end{aligned}\tag{11.6.23}$$

That is to say:

$$\begin{aligned}2\mathrm{i}\omega_+A_+e^{\mathrm{i}\omega_+t}&=\mathrm{i}\left(\omega_0A_+e^{\mathrm{i}\omega_+t}+\omega_AA_-e^{\mathrm{i}\omega t+\mathrm{i}\omega_-t}\right)\\2\mathrm{i}\omega_-A_-e^{\mathrm{i}\omega_-t}&=\mathrm{i}\left(\omega_AA_+e^{-\mathrm{i}\omega t+\mathrm{i}\omega_+t}-\omega_0A_-e^{\mathrm{i}\omega_-t}\right)\end{aligned}\tag{11.6.24}$$

and after simplification by the exponential and the pure imaginary number:

$$\begin{aligned}2\omega_+A_+&=\omega_0A_++\omega_AA_-e^{\mathrm{i}\omega t+\mathrm{i}\omega_-t-\mathrm{i}\omega_+t}\\2\omega_-A_-&=\omega_AA_+e^{-\mathrm{i}\omega t+\mathrm{i}\omega_+t-\mathrm{i}\omega_-t}-\omega_0A_-\end{aligned}\tag{11.6.25}$$

Hence:

$$\begin{aligned}2\omega_+A_+&=\omega_0A_++\omega_AA_-e^{\mathrm{i}(\omega+\omega_--\omega_+)t}\\2\omega_-A_-&=\omega_AA_+e^{-\mathrm{i}(\omega-\omega_++\omega_-)t}-\omega_0A_-\end{aligned}\tag{11.6.26}$$

We can get rid of the time dependence above by putting:

$$\omega_+=\omega_-+\omega\tag{11.6.27}$$

Our system then reduces to:

$$\begin{aligned}2\omega_+A_+&=\omega_0A_++\omega_AA_-\\2\omega_-A_-&=\omega_AA_+-\omega_0A_-\end{aligned}\tag{11.6.28}$$

Thus by rearranging:

$$\begin{aligned}A_+(2\omega_+-\omega_0)-\omega_AA_-&=0\\-\omega_AA_++A_-(2\omega_-+\omega_0)&=0\end{aligned}\tag{11.6.29}$$

which can be written in matrix form:

$$\begin{bmatrix}2\omega_+-\omega_0&-\omega_A\\-\omega_A&2\omega_-+\omega_0\end{bmatrix}\begin{pmatrix}A_+\\A_-\end{pmatrix}=0\tag{11.6.30}$$

To get a consistent solution (not all zero solutions) and unique one, the determinant of the matrix must be zero to be reversible (see section Linear Algebra page 1980). But the determinant of this matrix is:

$$\begin{aligned}&\det\left(\begin{bmatrix}2\omega_+-\omega_0&-\omega_A\\-\omega_A&2\omega_-+\omega_0\end{bmatrix}\right)=(2\omega_+-\omega_0)(2\omega_-+\omega_0)-(-\omega_A)(-\omega_A)\\&=(2\omega_+-\omega_0)(2\omega_-+\omega_0)-\omega_A^2=4\omega_+\omega_-+2\omega_+\omega_0-2\omega_-\omega_0-\omega_0^2-\omega_A^2\\&=4(\omega_-+\omega)\omega_-+2(\omega_-+\omega)\omega_0-2\omega_-\omega_0-\omega_0^2-\omega_A^2\\&=4\omega_-^2+4\omega\omega_-+2\omega_-\omega_0+2\omega\omega_0-2\omega_0\omega_0-\omega_0^2-\omega_A^2\\&=4\omega_-^2+4\omega\omega_-+2\omega\omega_0-\omega_0^2-\omega_A^2\end{aligned}\tag{11.6.31}$$

But the roots of this polynomial of second degree in ω_- are (see section Calculus page 1383):

$$\begin{aligned}\omega_{-,1,2}&=\frac{-4\omega\pm\sqrt{(4\omega)^2-4\cdot 4\cdot(2\omega\omega_0-\omega_0^2-\omega_A^2)}}{2\cdot 4}\\&=\frac{-\omega\pm\sqrt{\omega^2-(2\omega\omega_0-\omega_0^2-\omega_A^2)}}{2}=\frac{-\omega\pm\sqrt{\omega^2-(2\omega\omega_0-\omega_0^2)+\omega_A^2}}{2}\\&=\frac{-\omega\pm\sqrt{\omega^2-2\omega\omega_0+\omega_0^2+\omega_A^2}}{2}=\frac{-\omega\pm\sqrt{(\omega-\omega_0)^2+\omega_A^2}}{2}\\&=-\frac{\omega}{2}\pm\frac{\sqrt{(\omega-\omega_0)^2+\omega_A^2}}{2}=-\frac{\omega}{2}\pm\Delta\omega\end{aligned} \tag{11.6.32}$$

So we deduce:

$$\omega_+=\omega_-+\omega\Rightarrow\omega_{+,1,2}=\omega_{-,1,2}+\omega=-\frac{\omega}{2}\pm\Delta\omega+\omega=+\frac{\omega}{2}\pm\Delta\omega \tag{11.6.33}$$

So we have for summary:

$$\begin{aligned}\omega_{-,1,2}&=-\frac{\omega}{2}\pm\Delta\omega\\\omega_{+,1,2}&=+\frac{\omega}{2}\pm\Delta\omega\end{aligned} \tag{11.6.34}$$

Results to inject in:

$$\begin{aligned}\alpha_+(t)&=A_+e^{\mathrm{i}\omega_+t}\\\alpha_-(t)&=A_-e^{\mathrm{i}\omega_-t}\end{aligned} \tag{11.6.35}$$

So as each pulsation has two solution, the general solution will be the sum of the special solutions (see section Differential and Integral Calculus page 1605). Let us focus on the second relation. We then have:

$$\alpha_-(t)=A_-e^{-\mathrm{i}\frac{\omega}{2}t}e^{+\mathrm{i}\Delta\omega t}+B_-e^{-\mathrm{i}\frac{\omega}{2}t}e^{-\mathrm{i}\Delta\omega t} \tag{11.6.36}$$

But let us recall the initial condition that we required for the second component of the spinor (due to the fact that the spinor is oriented to the top):

$$\alpha_-(0)=0 \tag{11.6.37}$$

Then we have:

$$A_-=-B_-:=A \tag{11.6.38}$$

Therefore:

$$\alpha_-(t)=Ae^{-\mathrm{i}\frac{\omega}{2}t}e^{+\mathrm{i}\Delta\omega t}-Ae^{-\mathrm{i}\frac{\omega}{2}t}e^{-\mathrm{i}\Delta\omega t} \tag{11.6.39}$$

with:

$$\dot{\alpha}_-(t)=\mathrm{i}A\left(-\frac{\omega}{2}+\Delta\omega\right)e^{-\mathrm{i}\frac{\omega}{2}t}e^{+\mathrm{i}\Delta\omega t}-\mathrm{i}A\left(-\frac{\omega}{2}-\Delta\omega\right)e^{-\mathrm{i}\frac{\omega}{2}t}e^{-\mathrm{i}\Delta\omega t} \tag{11.6.40}$$

and:

$$\dot{\alpha}_-(0)=\mathrm{i}A\left(-\frac{\omega}{2}+\Delta\omega\right)-\mathrm{i}A\left(-\frac{\omega}{2}-\Delta\omega\right)=2\mathrm{i}A\Delta\omega \tag{11.6.41}$$

Now, to determine A, we will use in a clever way the differential we started from earlier above:

$$2\dot{\alpha}(t)=\mathrm{i}\left(\omega_A e^{-\mathrm{i}\omega t\alpha_+(t)}-\omega_0\alpha_-(t)\right) \tag{11.6.42}$$

without forgetting the chosen initial conditions, we have:

$$2\dot{\alpha}(0)=\mathrm{i}\left(\omega_A e^{-\mathrm{i}\omega 0\alpha_+(0)}-\omega_0\alpha_-(0)\right)=\mathrm{i}(\omega_A\cdot 1-\omega_0\cdot 0)=\mathrm{i}\omega_A \tag{11.6.43}$$

Therefore:

$$\dot{\alpha}_-(0)=\frac{\mathrm{i}\omega_A}{2} \tag{11.6.44}$$

We must have the equality between the both expressions:

$$\begin{aligned}\dot{\alpha}_-(0)&=\frac{\mathrm{i}\omega_A}{2}\\ \dot{\alpha}_-(0)&=2\mathrm{i}A\Delta\omega\end{aligned} \tag{11.6.45}$$

and this can be satisfied obviously if and only if:

$$A=\frac{\omega_A}{4\Delta\omega} \tag{11.6.46}$$

Then we have:

$$\begin{aligned}\alpha_-(t)&=\frac{\omega_A}{4\Delta\omega}e^{-\mathrm{i}\frac{\omega}{2}t}\left(e^{+\mathrm{i}\Delta\omega t}-e^{+\mathrm{i}\Delta\omega t}\right)=\frac{\omega_A}{4\Delta\omega}e^{-\mathrm{i}\frac{\omega}{2}t}2\mathrm{i}\sin(\mathrm{i}\Delta\omega t)\\ &=\frac{\omega_A}{2\Delta\omega}\mathrm{i}\sin(\mathrm{i}\Delta\omega t)e^{-\mathrm{i}\frac{\omega}{2}t}\end{aligned} \tag{11.6.47}$$

Thus explicitly:

$$\alpha_-(t)=\frac{\omega_A}{\sqrt{(\omega-\omega_0)^2+\omega_A^2}}\mathrm{i}\sin(\mathrm{i}\Delta\omega t)e^{-\mathrm{i}\frac{\omega}{2}t} \tag{11.6.48}$$

As the second component of the spinor represents the angle and what we have above represents the angular position over time, the term:

$$\boxed{\frac{\omega_A}{\sqrt{(\omega-\omega_0)^2+\omega_A^2}}} \tag{11.6.49}$$

can be seen as the maximum value of the amplitude of the angle (Larmor rotation of the spin of the electron around the magnetic field). This maximum amplitude has itself a maximum if the denominator is as small as possible and therefore:

$$\omega=\omega_0=\frac{g\mu}{\hbar}B_0 \tag{11.6.50}$$

Then we say that there is "spin resonance".

So the magnetic field may make switch the energy state of each spin if the oscillation amplitude is maximum. As we have just proved above for an isolated particle, the energy change from one state to the other is:

$$E_\pm=\pm\frac{1}{2}\hbar\omega \tag{11.6.51}$$

and therefore when a spin flip it generates the emission of radiation named "free induction decay". The collected signal depends on several parameters that characterize the particle or the nuclear core. In short, in practice it is 99% engineering and 1% theory!

When we apply these theoretical results to an unpaired electron, that is to say, for the "electronic magnetic resonance", we have the following experimental data for a constant field $B_0 \cong 0.3$ [T]:

$$f \cong 10\,[\text{GHz}],\ \lambda \cong 3\,[\text{cm}],\ E_\gamma = \Delta E \cong 4 \cdot 10^{-4}\,[\text{eV}] \tag{11.6.52}$$

and therefore the electronic magnetic resonance technology is based on the detection of microwaves.

When we apply these theoretical results to a nuclear core of a single proton, that is to say, for the "nuclear magnetic resonance", we have the following experimental data for a constant field $B_0 \cong 1$ [T]:

$$f \cong 40\,[\text{MHz}],\ \lambda \cong 7\,[\text{m}],\ E_\gamma = \Delta E \cong 2 \cdot 10^{-7}\,[\text{eV}] \tag{11.6.53}$$

and therefore the nuclear magnetic resonance technology is based on the detection of radio waves.

Nowadays, nuclear magnetic resonance is also used to check the quality of food. For example, modern machines can detect whether orange juice is contaminated with juice from other fruit and can check whether the fruit were ripe when pressed. Other machines can check whether wine was made from the correct grapes and how it aged.

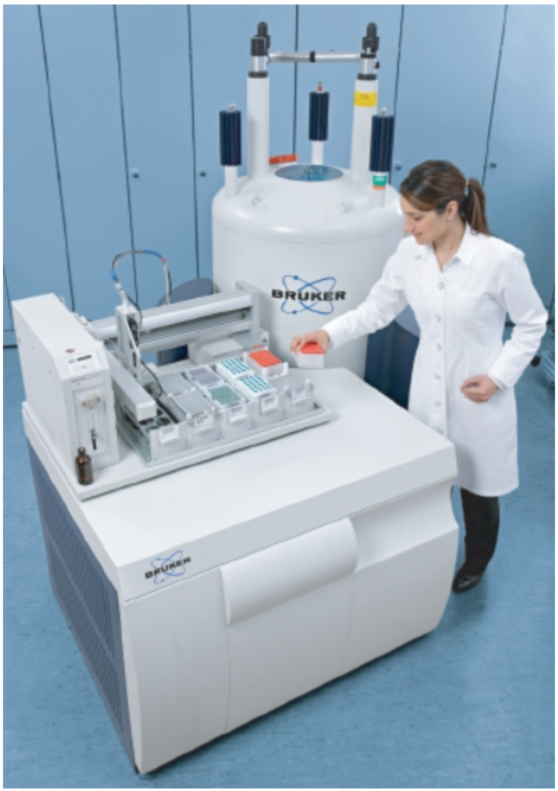

Figure 11.159: Machine to test fruit quality with the help of nuclear magnetic resonance (source: Bruker)

12.1. Astronomy (Celestial Mechanics)

CELESTIAL MECHANICS is the consequence of the universal Newton's law of attraction (see page 5255) and of the fundamental principle of mechanics (see section Classical Mechanics page 3194). Its main objective is the description of the motion of astronomical objects such as stars and planets using physical and mathematical theories.

In this section we will approach the subject as always in this textbook, in the most elementary possible way (to this day the topics in this section are not technically beyond the level of what was done in the beginning of 120th century (holocene calendar) in the field of astronomy).

First we will make a warm up with a funny law on the living in the Universe ... (the Drake equation). Once completed this warm up, we will begin to "enumerate" Kepler's laws (often referring to the section of Classical Mechanics) and then study in detail the properties of Keplerian orbits thanks to our knowledge on classical mechanics and then to using Special Relativity, which will lead us to find a theoretical procession of studied orbitals. Then we will have fun to model approximately the variation of the duration of the day (or night) on the Earth based on the month and latitude. Finally, to finish in style, we will launch the detailed calculation of the five Lagrangian points!

Definition (#12.1.521): It seems that Plato formulated the goal of "astronomy" as the purpose to represent the visible motion of celestial bodies by a combination of uniform rotations on circles. This is actually a very reasonable approach since we know that every bounded motion (path) can be approximated by linear combinations of motions on circles with constant speeds. This approximation is named as we already know the "Fourier series", and this is how the motion of planets is represented even now, for the purposes of prediction and computation.

Remark

Modern astronomy, that of the end and beginning of the 121st century (holocene calendar), makes extensive use of statistical methods (i.e. Data Science/Data Mining). The reader interested on this topic can have an in-deep look at the page 6768 of this textbook or an overview in this excellent book [173].

Astronomy uses a lot of parameters (i.e. "constants") that can be determined only by experimental observations and most of them evolves (obviously!) through time. If the reader is interested in a good reference, we strongly recommend *Handbook of Space Astronomy and Astrophysics* (see [600]).

Caution! Astronomy must not be confused with "Astrology". The latter has not demonstrated its effectiveness in controlled studies and has no scientific validity, and is thus regarded as pseudoscience and a source of income for charlatans (that are not able to found a real job...) that dupe naive and fragile people.

12.1.1 Sun, Moon distances and radii

We have already see how to determine the radius of the Earth in the section of Trigonometry using the method of Al-Bīrūnī (see page 2529) or that of Eratosthenes (see page 2579).

However in this section we will use plenty of times the radius and the distance of the Sun (actually a G2V-type star, aka yellow dwarf) and the Moon. And as requested by some readers, a question arise: what is the oldest and simplest method used to determine these two parameters?

For that let us refer to *On the Sizes and Distances (of the Sun and Moon)* widely accepted as the only extant work written by Aristarchus of Samos, an ancient Greek astronomer who lived circa 9700-9800 century according to holocene calendar (therefore long time before Al-Bīrūnī and almost a century before Eratosthenes). This work calculates the sizes of the Sun (actually a G2V-type star, aka yellow dwarf) and Moon, as well as their distances from the Earth in terms of Earth's radius (that was unknown at his time as determined only later by Eratosthenes!).

Aristarchus began with the premise that, during a half Moon, the Moon forms a right triangle with the Sun (actually a G2V-type star, aka yellow dwarf) and Earth. By observing the angle between the Sun and Moon, φ, the ratio of the distances to the Sun and Moon could be deduced using a form of trigonometry.

Remark

We often associate the Sun with daytime and the Moon with nighttime. The Sun is obviously not visible at night, but the Moon can certainly be observed in broad daylight and it is not always visible at night. It all depends on its phase! But if we associate the Moon with nighttime, it is because we notice it much more easily at night than during the day.

Definitions (#12.1.522): There are three types of twilight, which are stages of partial darkness before nightfall or after sunrise, and night itself. These are civil, nautical, and astronomical twilight, each defined by the position of the Sun below the horizon:

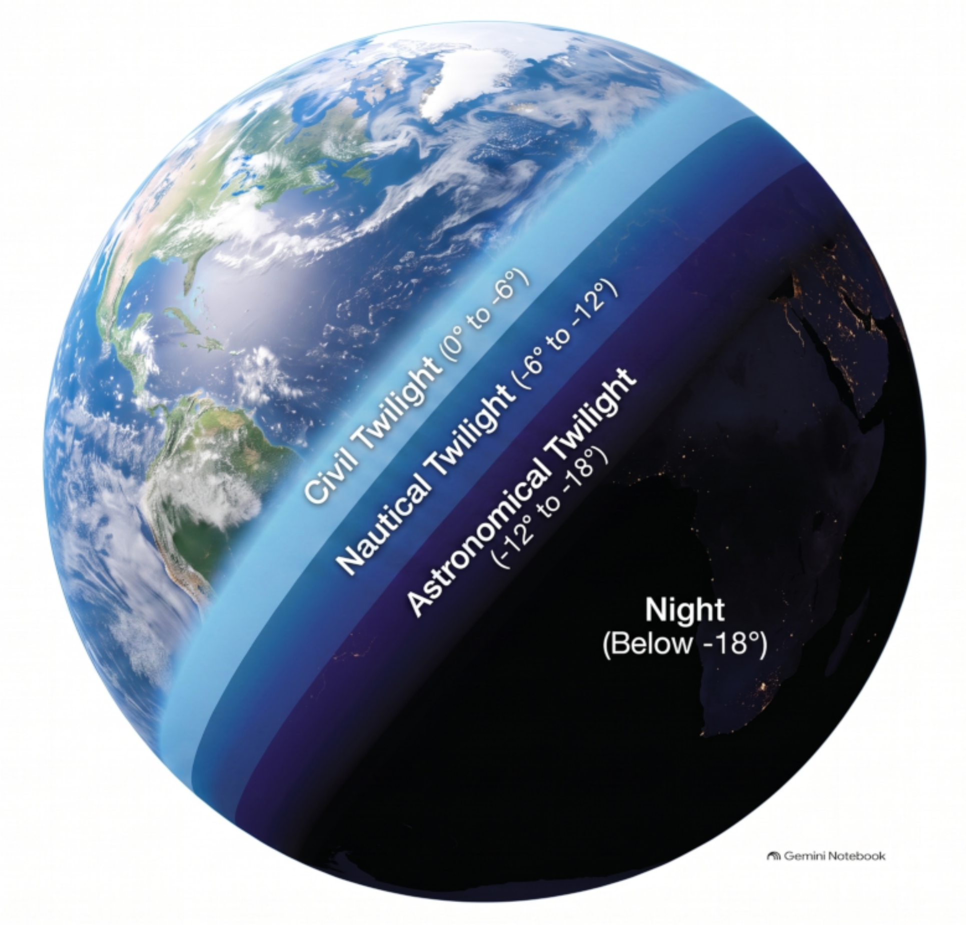
D1. The "civil twilight" is when the Sun is between 0 and 6 degrees below the horizon. This is when it's bright enough to see and do some activities without artificial light, but streetlights and vehicle headlights are often used.

D2. The "nautical twilight" is when Sun is between 6 and 12 degrees below the horizon. It's dark enough that the horizon is still somewhat visible for navigation at sea, as the brightest stars become visible.

D3. The "astronomical twilight" is when the Sun is between 12 and 18 degrees below the horizon. It's dark enough that the sky is beginning to appear dark for astronomical observations.

D4. The "night" is when the Sun is 18 degrees or more below the horizon, it's considered night, and the sky is generally dark, allowing for full stargazing.

These different twilights that exist due to light refraction and Rayleigh diffusion is one of the reason that every day more of the 50% of the Earth is not in the dark[1].



---

[1] Caution! Some newspapers claim that once a year 90% to 99% of the World population is under the light of the day plus of the three twilights. However without citing any scientific peer-review paper that confirms these claims! Remember that what is claimed without evidence can be rejected without evidence...

Let us also introduce some other important definitions:

Definitions (#12.1.523):

D1. For computational purposes, in compliance with the Astronomical Applications Department of the U.S. Naval Observatory, the "sunrise" or "sunset" is defined to occur when the geometric zenith distance of center of the Sun is 90.8333 degrees. That is, the center of the Sun is geometrically 50 arcminutes below a horizontal plane. For an observer at sea level with a level, unobstructed horizon, under average atmospheric conditions, the upper limb of the Sun will then appear to be tangent to the horizon. The 50-arcminute geometric depression of the Sun's center used for the computations is obtained by adding the average apparent radius of the Sun (16 arcminutes) to the average amount of atmospheric refraction at the horizon (34 arcminutes).

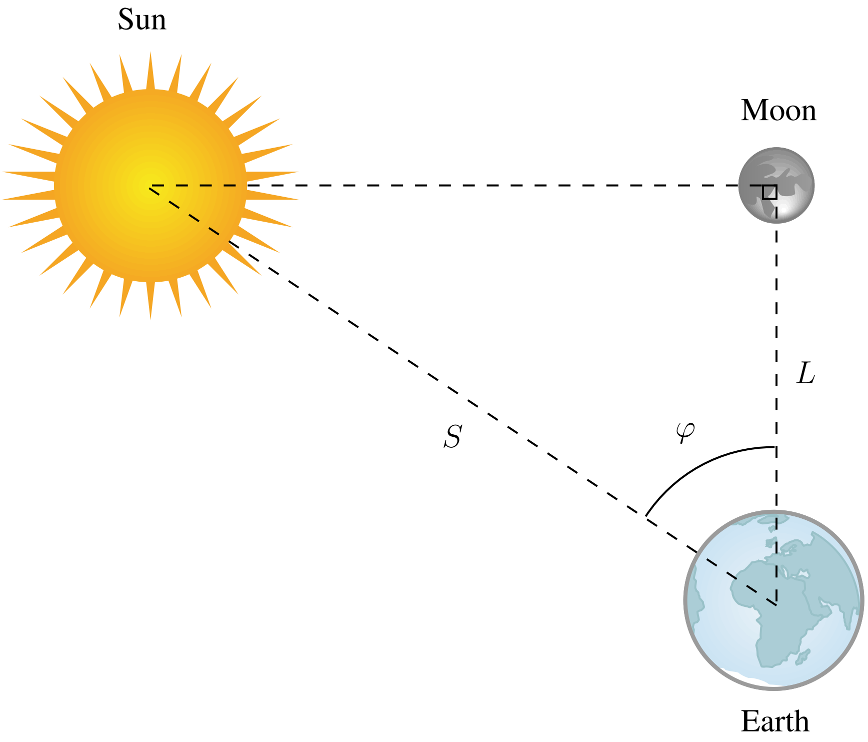
D2. For computational purposes, in compliance with the Astronomical Applications Department of the U.S. Naval Observatory, the "moonrise" and "moonset" are defined similarly, but the situation is computationally more complex because of the nearness of the Moon and the eccentricity of its orbit. If the computations are carried out using coordinates of the Moon with respect to the Earth's center (the usual method), then moonrise or moonset is defined to occur when the geometric zenith distance of the center of the Moon is:

$$90.5666\text{ degrees } + \text{Moon's apparent angular radius} - \text{Moon's horizontal parallax}$$

Under normal atmospheric conditions at sea level, the upper limb of the Moon will then appear to be tangent with a level, unobstructed horizon. No account is taken of the Moon's phase; that is, the Moon is always regarded as a disk in the sky and the upper limb might be dark. Here again, a constant of 34 arcminutes (0.5666 degree) is used to account for atmospheric refraction. The Moon's apparent radius varies from 15 to 17 arcminutes and its horizontal parallax varies from 54 to 61 arcminutes. Adding all the terms above together, the center of the Moon at rise or set is geometrically 5 to 10 arcminutes above the observer's "geocentric horizon" - the horizontal plane that passes through the Earth's center, orthogonal to the observer's local vertical.

D3. A " full Moon" is a lunar phase that occurs when the Moon is approximately opposite the Sun from Earth, that is, when their celestial longitude difference is about 180° (new and full Moons are sometimes named " syzygy" when the Sun and Moon are in conjunction or opposition, respectively, although they are not perfectly aligned with Earth), that is, the Moon is in geocentric opposition. At this time, the Moon's visible side is entirely illuminated by the Sun (due to the limited resolving power of the human eye, a full Moon is considered to occur when the illumination is $\geq 99\%$). The previous definition might suggest an elongation of 180° to the Sun at the instant of each full Moon, but due to the inclination of the lunar orbit (about 5.145°), the angular distance to the Sun at the instant of the full Moon is less. As a consequence, this angular distance can therefore be of the order of 175° and not 180° which makes possible cases of simultaneous observation of the Moon and the Sun at the same time at the precise moment of the full Moon when the observer is typically located near the terminator. This observation may be facilitated by atmospheric refraction which can raise each of the two objects up to 0.88°.

Let us consider the following configuration[2] (obviously not to scale...):



From the diagram and trigonometry, we can calculate that:

$$\frac{S}{L}=\frac{1}{\cos\varphi} \tag{12.1.1}$$

The diagram is greatly exaggerated, because in reality, $S=390\cdot L$, and φ is extremely close to $90°$. Aristarchus determined φ to be a thirtieth of a quadrant (in modern terms, $3°$) less than a right angle: in current terminology, $87°$. Trigonometric functions had not yet been invented, but using geometrical analysis in the style of Euclid, Aristarchus determined that:

$$18<\frac{S}{L}<20 \tag{12.1.2}$$

often denoted:

$$18<\hat{s}<20 \tag{12.1.3}$$

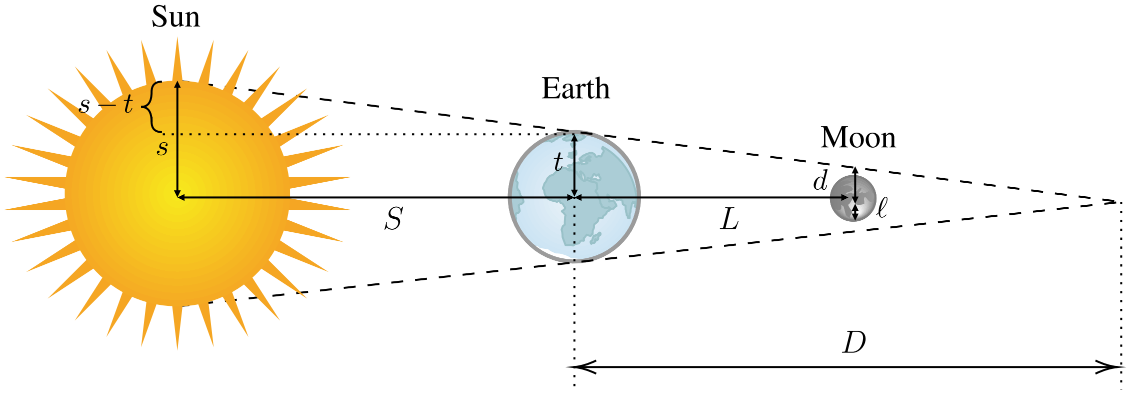
In other words, the distance to the Sun (actually a G2V-type star, aka yellow dwarf) was somewhere between 18 and 20 times greater than the distance to the Moon. This value (or values close to it) was accepted by astronomers for the next two thousand years, until the invention of the telescope permitted a more precise estimate of solar parallax.

Aristarchus also reasoned that as the angular size of the Sun and the Moon were the same, but the distance to the Sun was between 18 and 20 times further than the Moon, the Sun must therefore be 18–20 times larger.

---

[2] If you want a video in real life of the situation you can have a look at `https://www.youtube.com/watch?v=H0Dm_z5oyD4`

Aristarchus then used another construction based on a lunar eclipse as illustrated below (obviously not to scale and don't forget that actually when there is a lunar eclipse only a fraction of the Earth shadow cast on the Moon!):



By similarity of the triangles (see section Euclidean Geometry page 2610), we have:

$$\frac{D}{L}=\frac{t}{t-d} \quad \text{and} \quad \frac{D}{S}=\frac{t}{s-t} \tag{12.1.4}$$

Dividing these two equations and using the observation that the Sun and Moon appear to have the same apparent size (at least actually...) to people on Earth :

$$\frac{s}{S}=\frac{\ell}{L} \tag{12.1.5}$$

yields:

$$\frac{\ell}{s}=\frac{t-d}{s-t} \Longrightarrow \frac{s-t}{s}=\frac{t-d}{\ell} \Longrightarrow \frac{t}{\ell}+\frac{t}{s}=1+\frac{d}{\ell} \tag{12.1.6}$$

The rightmost equation can either be solved for ℓ/t or s/t. Indeed:

$$\frac{t}{\ell}+\frac{t}{s}=1+\frac{d}{\ell} \Rightarrow \frac{t}{\ell}\left(1+\frac{\ell}{s}\right)=1+\frac{d}{\ell} \Rightarrow \frac{\ell}{t}=\frac{1+\dfrac{\ell}{s}}{1+\dfrac{d}{\ell}} \tag{12.1.7}$$

and:

$$\frac{t}{\ell}+\frac{t}{s}=1+\frac{d}{\ell} \Rightarrow \frac{t}{s}\left(\frac{s}{\ell}+1\right)=1+\frac{d}{\ell} \Rightarrow \frac{s}{t}=\frac{1+\dfrac{s}{\ell}}{1+\dfrac{d}{\ell}} \tag{12.1.8}$$

So finally (the first ratio ℓ/t for reminder is therefore the Moon radius on the Earth's radius and the second ratio s/t is the Sun radius on the Earth radius):

$$\frac{\ell}{t}=\frac{1+\dfrac{\ell}{s}}{1+\dfrac{d}{\ell}} \qquad \frac{s}{t}=\frac{1+\dfrac{s}{\ell}}{1+\dfrac{d}{\ell}} \tag{12.1.9}$$

These equations can be made to appear simpler by expressing the lengths d and s in terms of the Moon's radius ℓ as a unit, defining $\hat{d}=d/\ell$ and $\hat{s}=s/\ell$. Then:

$$\frac{\ell}{t}=\frac{1+\hat{s}}{\hat{s}(1+\hat{d})} \qquad \frac{s}{t}=\frac{1+\hat{s}}{1+\hat{d}} \tag{12.1.10}$$

Using $\hat{d}=2$ (a guess by looking Earth's shadow on the Moon during the lunar eclipse) and $\hat{s}=19.1$ (from the first result we got earlier above where $18<\hat{s}<20$):

$$\frac{\ell}{t}=\frac{1+\hat{s}}{\hat{s}(1+\hat{d})}\cong 0.35 \qquad \frac{s}{t}=\frac{1+\hat{s}}{1+\hat{d}}\cong 6.7 \tag{12.1.11}$$

More often presented as:

$$\frac{t}{\ell}=\frac{\hat{s}(1+\hat{d})}{1+\hat{s}}\cong 2.85 \qquad \frac{s}{t}=\frac{1+\hat{s}}{1+\hat{d}}\cong 6.7 \tag{12.1.12}$$

To compare with modern values where we have $t/\ell\cong 3.67$ (Earth's radius on Moon's radius) and $s/t\cong 109$ (Sun's radius on Earth's radius).

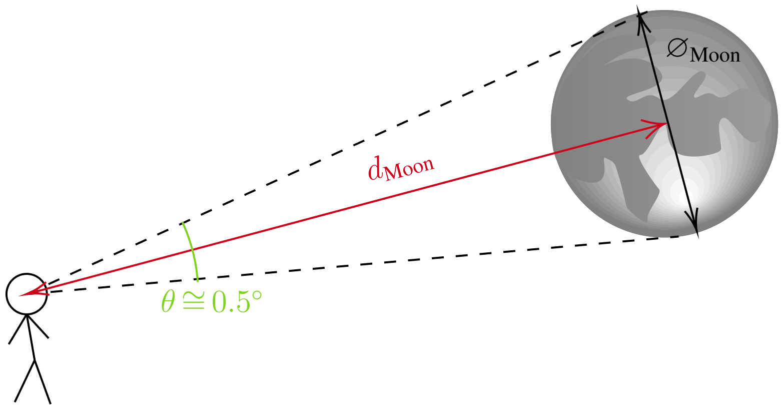
The error in this calculation comes primarily from the poor values for $\hat{s}$.

Remember that we know the Earth's radius using the method of Al-Bīrūnī (see page 2529) and also based on that of Eratosthenes (see page 2579), that was given by the approximate value of $6,266$ kilometres. Therefore we get for the diameter of the Moon using the results of Aristarchus:

$$\varnothing_{\text{Moon}}=\frac{2\cdot 6,266}{2.85}\cong 4,397\,[\text{km}] \tag{12.1.13}$$

where modern measurements give actually approximately $3,474.3$ kilometres.

Now let's go for the distances! We consider for that the observation of a full Moon (can easily be done by anyone) or of a Solar eclipse (indeed we are for the moment lucky - but it's temporary - that we can see that the Moon has quite the same angular diameter as that from the Sun):



Using basic trigonometry we get using the initial values of Aristarchus:

$$d_{\text{Moon}}\cong\frac{4,397/2}{\tan(0.5/2)}\cong 500,000\,[\text{km}] \tag{12.1.14}$$

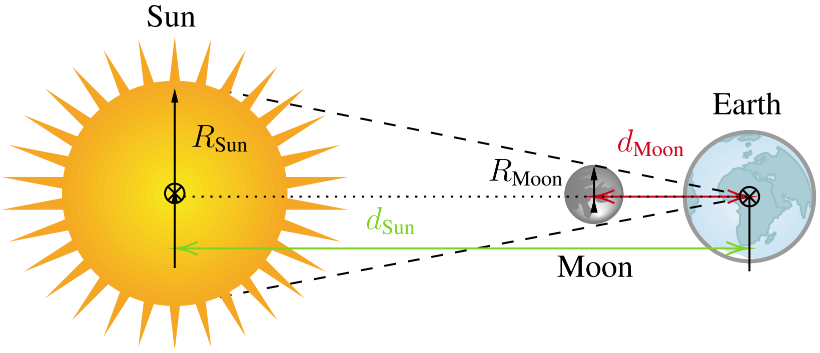
To compare with the modern average value of $384,400$ kilometers known with various methods like radar echoes or LASER ranging.

Now to deal with the case of the Sun, let us first thanks to the result above and our knowledge of the Earth radius, calculate the radius of the Sun (actually a G2V-type star, aka yellow dwarf) according to the quite (very) wrong values of Aristarchus:

$$\varnothing_{\text{Sun}}=(2\cdot 6,266)\cdot 6.7=83,964.4\,[\text{km}] \tag{12.1.15}$$

in comparison of the modern values that is $1,392,680$ kilometres (...). To see the various methods developed through the centuries to measure the average Earth-Sun distance the reader can refer to [371].

And now with all these values and using the following configuration typical of Solar eclipse (obviously not to scale) we can determine the corresponding quite (very) wrong value of the distance of the Sun from the Earth:



By similarity of the triangles (see section Euclidean Geometry page 2610):

$$\frac{R_{\text{Sun}}}{d_{\text{Sun}}}=\frac{R_{\text{Moon}}}{d_{\text{Moon}}}\Rightarrow d_{\text{Sun}}=\left(\frac{d_{\text{Moon}}}{R_{\text{Moon}}}\right)R_{\text{Sun}} \tag{12.1.16}$$

Hence:

$$d_{\text{Sun}}=\left(\frac{d_{\text{Moon}}}{R_{\text{Moon}}}\right)R_{\text{Sun}}=\frac{500,000}{4,397/2}\cdot(83,964.4/2)\cong 9,547,919\,[\text{km}] \tag{12.1.17}$$

To compare to the modern average value of approximately 149.6 millions kilometers (...)!

Remark

A similar procedure was later used by Hipparchus, who estimated the mean distance to the Moon as 67 Earth radii, and Ptolemy, who took 59 Earth radii for this value.

So that was quite funny to see how to calculate the most used dimensions in astronomy based on very old and simple methods. However, we will obviously here for the remaining part of this textbook use the values available in tables determined with modern tools and modern observational and statistical methods!

12.1.2 Drake Equation

This equation was invented (...) by Francis Drake in the 11960s (holocene calendar) with the intention to discuss the number of extraterrestrial civilizations in our Galaxy with which we might come in contact in the context of the SETI program (Search for ExtraTerrestrial Intelligence). The main purpose of this equation for scientists is to determine its factors, in order to know the likely number and (very) estimated extraterrestrial civilizations.

This empirical and naive equation which remains more something funny and provocative than something else... and whose principle can be applied to a lot of different areas of physics and life is written:

$$\boxed{N=N^*f_pn_ef_lf_if_cf_L} \tag{12.1.18}$$

The terms of this formula (because it is a formula and not a relation!) are defined as follows (the notation can differs as the reader can see it in the figure further below):

- N^* represents the number of stars in a single galaxy
- f_p is the fraction of stars that would have an orbiting planet (between 0 and 1)
- n_e is the number of planets per star that fulfil the conditions for the development of life
- f_l is the fraction of planets whose life has emerged (between 0 and 1)
- f_i is the fraction of those where an intelligent life has emerged (between 0 and 1)
- f_c is the fraction of f_i which has implemented radio communication technology (between 0 and 1)
- f_l is the fraction of time during which the fraction f_i civilizations will live (between 0 and 1)

In practice, it should be noted that this formula purpose is to try to determine an unknown amount from other amounts that are also unknown ... But it's a nice and funny formula to evaluate when you discuss with friends at the restaurant...

Researchers have suggested adding two new factors to the equation:

$$N=N^*f_pn_ef_lf_if_cf_Lf_of_t \tag{12.1.19}$$

where:

- f_o fraction of habitable planets with both continents and oceans
- f_t fraction of those planets with plate tectonics operating for at least 500 million years

There is therefore no guarantee that we are more knowledgeable after the estimate of this formula than before (method sometimes named in the literature "garbage in, garbage out"...).

The resulting value can motivate the fact that following mathematical developments are not only applicable to only one solar (star) system in the universe... maybe... (it would make a lot of useless empty space otherwise...).

Making a punctual estimates of a guess being obviously a nonsense we have to refer to Monte Carlo simulation (see section Numerical Methods pages pagerefmonte carlo simulations) as done in [186] if we want an estimate of N and results were:

Variable	**Mean**	**Standard Deviation**
$N_{\text{planets,total}}$	$4.770 \cdot 10^8$	381
$N_{\text{inhabited}}$	$80,090$	22
$N_{\text{fledgling}}$	728.6	1
$N_{\text{destroyed}}$	367.3	0
N_{advanced}	361.2	2

Table 12.1: **Statistics for the Rare Life Hypothesis (source: [186])**

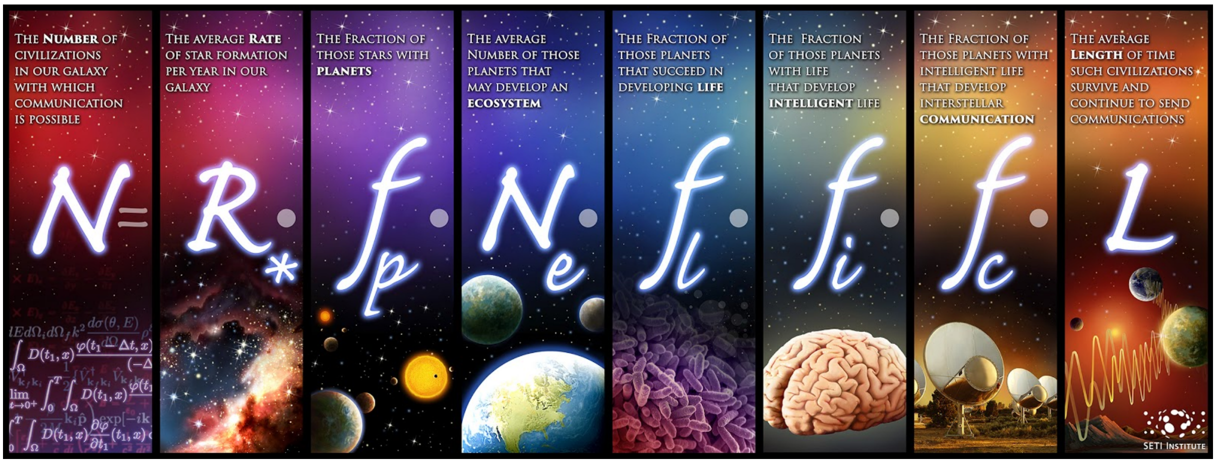
Let us talk now about the "Fermi paradox" named after physicist Enrico Fermi, is the apparent contradiction between the lack of evidence and high probability estimates, e.g., those given by the Drake equation, for the existence of extraterrestrial civilizations. The basic points of the argument, made by physicists Enrico Fermi (11901–11954 according to holocene calendar) and Michael H. Hart (born in 11932 according to holocene calendar), are:

- There are billions of stars in the galaxy that are similar to the Sun, many of which are billions of years older than Earth.
- With high probability, some of these stars will have Earth-like planets, and if the Earth is typical, some might develop intelligent life.
- Some of these civilizations might develop interstellar travel, a step the Earth is investigating now.
- Even at the slow pace of currently envisioned interstellar travel, the Milky Way galaxy could be completely traversed in a few million years.

According to this line of reasoning, the Earth should have already been visited by extraterrestrial aliens. In an informal conversation, Fermi noted no convincing evidence of this, leading him to ask, "Where is everybody?" There have been many attempts to explain the Fermi paradox, primarily either suggesting that:

- Extraterrestrial life is rare or non-existent
- No other intelligent species have arisen
- Civilizations lack advanced technology
- It is the nature of intelligent life to destroy itself
- It is the nature of intelligent life to destroy others
- There is periodic extinction by natural events
- Intelligent civilizations are too far apart in space or time

- It is too expensive to spread physically throughout the galaxy
- Human beings have not existed long enough
- Humans are not listening properly
- Civilizations broadcast detectable radio signals only for a brief period of time
- Civilizations tend to isolate themselves
- Everyone is listening, no one is transmitting
- Earth is deliberately not contacted
- It is dangerous to communicate
- ...



The Number of civilizations in our galaxy with which communication is possible
N =
The average Rate of star formation per year in our galaxy
R*
The fraction of those stars with planets
f p
The average number of those planets that may develop an ecosystem
N e
The fraction of those planets that succeed in developing life
f l
The fraction of those planets with life that develop intelligent life
f i
The fraction of those planets with intelligent life that develop interstellar communication
f c
The average length of time such civilizations survive and continue to send communications

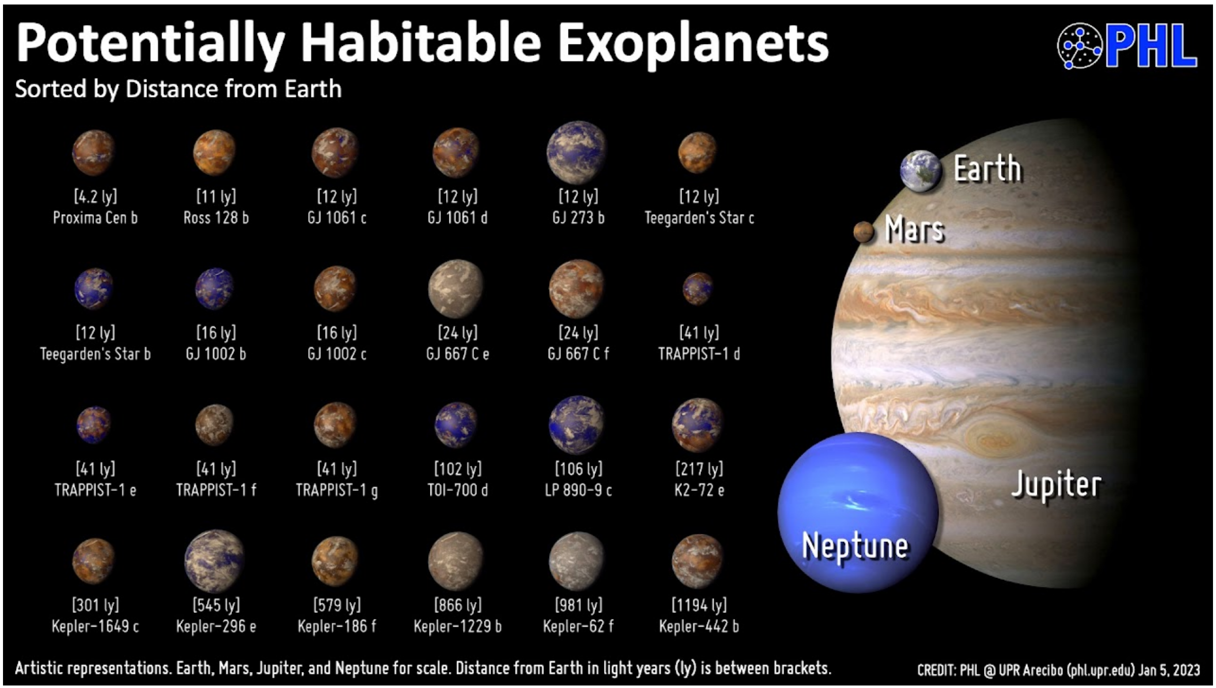
Figure 12.1: **Drake equation**

12.1.2.1 Habitale Zone (HZ)

In astronomy and astrobiology, the "circumstellar habitable zone" (CHZ), or simply the habitable zone, is the range of orbits around a star within which a planetary surface can support liquid water given sufficient atmospheric pressure. The bounds of the CHZ are based on Earth's position in the Solar System and the amount of radiant energy it receives from the Sun (actually a G2V-type star, aka yellow dwarf). Due to the importance of liquid water to Earth's biosphere, the nature of the CHZ and the objects within it may be instrumental in determining the scope and distribution of planets capable of supporting Earth-like extraterrestrial life and intelligence.

Since the concept was first presented in 11953 (holocene calendar), many stars have been confirmed to possess a CHZ planet, including some systems that consist of multiple CHZ planets. Most such planets, being either super-Earths or gas giants, are more massive than Earth, because massive planets are easier to detect. On November 4, 2013, astronomers reported, based on Kepler data, that there could be as many as 40 billion Earth-sized planets orbiting in the habitable zones of Sun-like stars and red dwarfs in the Milky Way. About 11 billion of these may be orbiting Sun-like stars. Proxima Centauri b, located about 4.2 light-years (1.3 parsecs) from Earth in the constellation of Centaurus, is the nearest known exoplanet, and is orbiting in the habitable zone of its star.



Potentially Habitable Exoplanets

Figure 12.2: A small sample of potentially habitable planets according to Kepler's date

The CHZ is also of particular interest to the emerging field of habitability of natural satellites, because planetary-mass moons in the CHZ might outnumber planets.

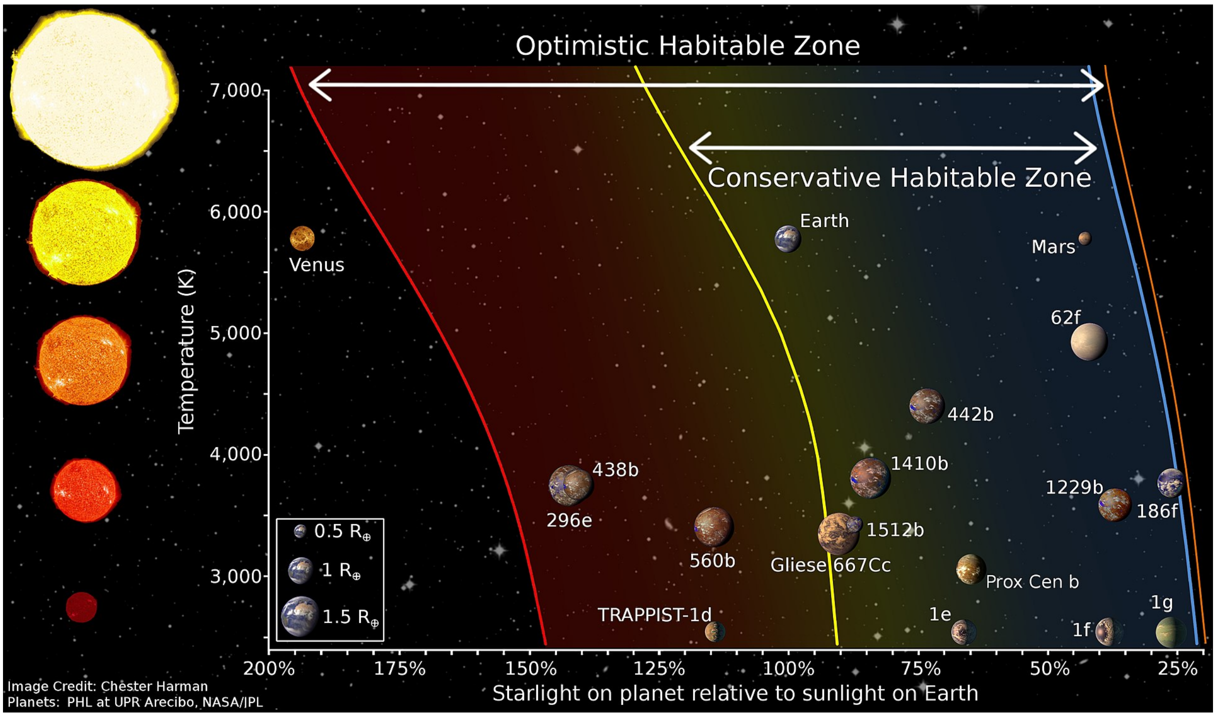

Figure 12.3: Diagram depicting the habitable zone boundaries around stars, and how the boundaries are affected by star type (author: Chester Harman)

In subsequent decades, the CHZ concept began to be challenged as a primary criterion for life, so the concept is still evolving. Since the discovery of evidence for extraterrestrial liquid water, substantial quantities of it are now thought to occur outside the circumstellar habitable zone. The concept of deep biospheres, like Earth's, that exist independently of stellar energy, are now generally accepted in astrobiology given the large amount of liquid water known to exist within in lithospheres and asthenospheres of the Solar System. Sustained by other energy sources, such as tidal heating or radioactive decay or pressurized by non-atmospheric means, liquid water may be found even on rogue planets, or their moons. Liquid water can also exist at a wider range of temperatures and pressures as a solution, for example with sodium chlorides in seawater on Earth, chlorides and sulphates on equatorial Mars, or ammoniates, due to its different colligative properties. In addition, other circumstellar zones, where non-water solvents favorable to hypothetical life based on alternative biochemistries could exist in liquid form at the surface, have been proposed.

Estimates for the habitable zone within the Solar System range from 0.38 to 10.0 astronomical units, though arriving at these estimates has been challenging for a variety of reasons. Numerous planetary mass objects orbit within, or close to, this range and as such receive sufficient sunlight to raise temperatures above the freezing point of water. However, their atmospheric conditions vary substantially.

Circumstellar habitable zones change over time with stellar evolution. For example, hot O-type stars, which may remain on the main sequence for fewer than 10 million years, would have rapidly changing habitable zones not conducive to the development of life. Red dwarf stars, on the other hand, which can live for hundreds of billions of years on the main sequence, would have planets with ample time for life to develop and evolve. Even while stars are on the main sequence, though, their energy output steadily increases, pushing their habitable zones farther out; our Sun, for example, was 75% as bright in the Archaean as it is now, and in the future, continued increases in energy output will put Earth outside the Sun's habitable zone, even before it reaches the red giant phase.

Figure 12.4: **Sun expanding habitable zone (author: Roen Kelly)**

Now let us see the maths for a very idealistic simple case restricted to the special case of the actual state of our Sun (with a Solar constant of $1,360.8\,[\mathrm{W}\cdot\mathrm{m}^{-2}]$) and an Earth (assumed to be here a perfect sphere) behaving like a black body and not having an internal source of heat and having its rotation axis perpendicular to the equatorial plane of the Sun. Let us calculate the closest and farthest distances from the Sun where an inert that rotates rapidly enough to guarantee the absence of gradient of temperature planet would have to allow water to exist in a liquid state. We will also Assume the albedo is 0.31 (i.e. 31% of light reflected) and that the atmosphere of the planet raises the surface temperature by $30\,[^\circ\mathrm{C}]$ (greenhouse effect as seen in the section of Weather Engineering page 8275) and that the only factor of interest is the state of water that has to be in liquid state in normal condition of pressure, i.e. with a temperature T between $0\,[^\circ\mathrm{C}]$ and $100\,[^\circ\mathrm{C}]$ (i.e. $273.15\,[\mathrm{K}]$ and $373.15\,[\mathrm{K}]$).

Let us remind the area of a sphere:

$$S=4\pi R^2 \tag{12.1.20}$$

The incident radiation from the Sun (actually a G2V-type star, aka yellow dwarf) can be calculated from its luminosity (which in turn could have been derived from its black-body flux as given by the Stefan-Boltzmann law; integrated over its surface):

$$M_\odot = \frac{L_\odot}{4\pi d^2} \tag{12.1.21}$$

with d the distance between the Sun and the Earth (i.e. $1\,[\text{AU}] = 149,597,870,700\,[\text{m}]$). The energy absorbed by the Earth, then becomes:

$$E_{\text{in}} = M_\odot \pi R^2_{\text{Earth}}\,(1-A) = \frac{L_\odot R^2_{\text{Earth}}\,(1-A)}{4d^2} \tag{12.1.22}$$

where $\rho = 0.31$ is the Earth's albedo, i.e. the fraction of the incoming flux that is not absorbed. The energy lost in black-body radiation, is given by:

$$E_{\text{out}} = 4\pi R^2_{\text{Earth}}\,\sigma T^4_{\text{Earth}} \tag{12.1.23}$$

with $\sigma T^4_{\text{Earth}}$ the blackbody flux as defined by the Stefan-Boltzmann law.

Equating these two, we get:

$$4\pi R^2_{\text{Earth}}\,\sigma T^4_{\text{Earth}} = \frac{L_\odot R^2_{\text{Earth}}\,(1-\rho)}{4D^2} \tag{12.1.24}$$

Hence:

$$d = \sqrt{\frac{L_\odot (1-\rho)}{16\pi\sigma T^4_{\text{Earth}}}} \tag{12.1.25}$$

or, after re-writing:

$$d = \sqrt{\frac{L_\odot (1-\rho)}{16\pi\sigma T^4_{\text{Earth}}}} = \sqrt{\frac{3.846\cdot 10^{26}\,[\text{W}]\cdot 0.69}{16\pi 5.67\cdot 10^{-8}\,[\text{W}\cdot\text{m}^{-2}\cdot\text{K}^{-4}]\cdot T^4_{\text{Earth}}}} = \frac{0.96\cdot 10^{16}\,[\text{mK}^2]}{T^2_{\text{Earth}}} \tag{12.1.26}$$

For $T = 273\,[\text{K}] - 30\,[\text{K}] = 245\,[\text{K}]$ (taking into account the greenhouse effect mentioned earlier that must be substracted from the temperature need from the stare alone), this becomes:

$$d_{\max} = 1.29\cdot 10^{11}\,[\text{m}] = 1.08\,[\text{AU}] \tag{12.1.27}$$

and for $T = 373\,[\text{K}] - 30\,[\text{K}] = 343\,[\text{K}]$, we get:

$$d_{\min} = 6.94\cdot 10^{10}\,[\text{m}] = 0.655\,[\text{AU}] \tag{12.1.28}$$

Hence a habitable zone range of:

$$d_{\max} - d_{\min} = 64,586,662.39\,[\text{km}] \tag{12.1.29}$$

Ok that's the CHZ range for liquid water! But now, for the fun, let us be more restrictive by taking the ideal external temperature range for mammals (i.e. $17\,[^\circ\text{C}]$ to $24\,[^\circ\text{C}]$). Therefore we have:

$$d_{\max} - d_{\min} = 0.949\,[\text{AU}] - 0.900\,[\text{AU}] = 7,348,702.56\,[\text{km}] \tag{12.1.30}$$

What is funny with that result is that Earth isn't even in the ideal range of distance from the Sun for mammals (at least for the moment as the Sun is increasing in size and its temperature increasing depending on the millions of years that pass...).

Obviously in the general case, the formula is:

$$\boxed{\Delta d_{\text{CHZ}} = \sqrt{\frac{L_{\text{star}}(1-\rho)}{16\pi\sigma}}\left(\frac{1}{T_{\text{min}}^4}-\frac{1}{T_{\text{max}}^4}\right)} \tag{12.1.31}$$

So as we proved it, there is no "perfect position", nor "ideal position", nor "perfect position" for a planet around a star but just a range of acceptable positions (that furthermore depends with the time of the evolution of the orbiting star)!

A final word! The model above is obviously naive as it doesn't take into account explicitly the rotation speed of the planet, the type of radiation of the main star, the constitution of the atmosphere, the precession of the planet, nor the fact that it orbit may be strongly elliptic, and so on... and so on!

12.1.3 Kepler's Laws

In astronomy, Kepler's laws describe naively and approximatively the main properties of the motion of planets[3] and other celestial objects around a main star (or some other exotic stuff different than stars!), without explaining the reason (at least at the time these laws were developed!). They were discovered by Johannes Kepler based on the observations and measurements (in phenomenal amount) of the position of the planets made by Tycho Brahe, measures that were very accurate for its time.

Definition (#12.1.524): In astronomy an "orbit" is a closed curved path of a celestial object or spacecraft round a star, planet, or moon, especially a periodic elliptical revolution. In reality the planets and our Sun (and very likely most objects in our observable Universe) don't follow an orbit but an helicoidal path (as viewed from the center of our Galaxy) that projected on a plane (heliocentric referential) is in approximation similar to an orbit!

The first two Kepler's law seems to were published in 11609 (holocene calendar) and the third in 11618 (holocene calendar). The elliptical orbits, as set out in its first two laws can explain a part of the complexity of the apparent motion of the planets (but in reality the motion is chaotic and we need to rely on numerical Fourier series that need to be regularly corrected).

Soon after, in 11687 (holocene calendar) Isaac Newton discovered the law of gravitational attraction, deducting from it, by calculation, the three Kepler's laws.

Remark

Strictly speaking, pure Keplerian orbits can only occur with two bodies obeying Newton's law of gravitation. If there are more than two bodies then the orbits will be perturbed, to some degree. Kepler orbits are a reasonable first approximation to the orbits of the planets in the Solar System because the Sun is so massive compared to the planets, and the distances between the planets are relatively large, so the planets don't perturb each other's orbits very much.

Kepler was fortunate that he had sufficiently accurate data to see the patterns that led to his three laws of planetary motion, but not so accurate that he could see those laws were only a rough approximation. Fortunately, Newton came along a few decades later and showed how Kepler's laws were a consequence of the laws of mechanics and gravitation applied to two bodies. However, Newton also realised that the Moon's orbit around the Earth was significantly perturbed by the Sun. In fact, the Moon's motion is quite complex and its orbit precesses in various ways on rather short time scales.

We will now try to present these laws in the most relevant possible way:

---

[3] The definition of a "planet" is still a debate in the 121st century (holocene calendar) in a system in equilibrium... The reader can try to find a himself what should be a good definition for a "planet"and such an exercise will provide enough evidence that's not an easy task.

12.1.3.1 First Kepler's Law (conicity law)

The "first law of Kepler", sometimes also named "conicity law" or "law of orbits" is stated most of time as follow: The orbits of the planets are conics (ellipses) which the Sun (central star) occupies one of the focals.

In fact, it should be noted that this is not really a "law" in the proper sense, since further below you will see that we can prove that:

$$\boxed{r=\frac{p}{1+e\cos(\theta)}=\frac{b^2/a}{1+\sqrt{1-\dfrac{b^2}{a^2}}\cos(\theta)}} \tag{12.1.32}$$

where a is the semi-major axis and b is the semi-minor axis and $0\leq e\leq 1$ is the eccentricity[4] (see section Analytical Geometry page 2775).

Remark

The reader who has already read the section of Analytical Geometry will not be surprised by this relation (see page 2785)...

12.1.3.2 Second Kepler's Law (area law)

The "Kepler's second law", sometimes also named "area law" tells us that the line joining a planet to the Sun (central start) sweeps out equal areas in equal times (constant areal velocity) as:

$$\boxed{\frac{\Delta S}{\Delta t}=c^{te}} \tag{12.1.33}$$

It is a relation that arises from the conservation of angular momentum as we have already shown it in the section of Classical Mechanics where we got (see page 3244):

$$\frac{\mathrm{d}\vec{S}}{\mathrm{d}t}=\frac{\vec{b}}{2m}=\frac{\vec{r}\times(m\vec{v})}{2m}=c^{te} \tag{12.1.34}$$

So again, the status of "law" is questionable in the language of modern physics!

The latter relation is also in scalar form obviously written:

$$rv\sin(\theta)=c^{te} \tag{12.1.35}$$

where θ is the angle between the orbit radius and the tangential velocity vector of the object on its orbit.

---

[4] The eccentricity of the Earth's orbit varies over time, due to gravitational interaction with other celestial bodies. The eccentricity value can get as low as 0.0034 and up to 0.058. Because of the eccentricity the orbit of the Earth from the farthest (aphelion) to nearest (perihelion) point of the Sun its distance has a differential of almost 3 millions kilometers actually.

Now let us express this law in another form more conventional in the field of astronomy. Consider for this the movement in the plane the cylindrical coordinates given by:

$$\vec{x}(t)=r(t)\begin{pmatrix}\cos(\theta(t))\\ \sin(\theta(t))\\ 0\end{pmatrix} \tag{12.1.36}$$

Therefore:

$$\dot{\vec{x}}(t)=\dot{r}(t)\begin{pmatrix}\cos(\theta(t))\\ \sin(\theta(t))\\ 0\end{pmatrix}+r(t)\dot{\theta}(t)\begin{pmatrix}-\sin(\theta(t))\\ \cos(\theta(t))\\ 0\end{pmatrix} \tag{12.1.37}$$

It comes therefore from the property of linearity of the vector product:

$$\begin{aligned}\vec{b}&=m\vec{x}(t)\times\dot{\vec{x}}(t)=mr(t)\begin{pmatrix}\cos(\theta(t))\\ \sin(\theta(t))\\ 0\end{pmatrix}\times\left[\dot{r}(t)\begin{pmatrix}\cos(\theta(t))\\ \sin(\theta(t))\\ 0\end{pmatrix}+r(t)\dot{\theta}(t)\begin{pmatrix}-\sin(\theta(t))\\ \cos(\theta(t))\\ 0\end{pmatrix}\right]\\ &=mr(t)\left[\dot{r}(t)\begin{pmatrix}\cos(\theta(t))\\ \sin(\theta(t))\\ 0\end{pmatrix}\times\begin{pmatrix}\cos(\theta(t))\\ \sin(\theta(t))\\ 0\end{pmatrix}+r(t)\dot{\theta}(t)\begin{pmatrix}\cos(\theta(t))\\ \sin(\theta(t))\\ 0\end{pmatrix}\begin{pmatrix}-\sin(\theta(t))\\ \cos(\theta(t))\\ 0\end{pmatrix}\right]\\ &=mr(t)\left[\dot{r}(t)\begin{pmatrix}0\\ 0\\ \cos(\theta(t))\sin(\theta(t))-\sin(\theta(t))\cos(\theta(t))\end{pmatrix}+r(t)\dot{\theta}(t)\begin{pmatrix}0\\ 0\\ cos^2(\theta(t))+\sin^2(\theta(t))\end{pmatrix}\right]\\ &=mr(t)\left[\dot{r}(t)\begin{pmatrix}0\\ 0\\ 0\end{pmatrix}+r(t)\theta(\dot{t})\begin{pmatrix}0\\ 0\\ 1\end{pmatrix}\right]=mr(t)r(t)\dot{\theta}(t)\begin{pmatrix}0\\ 0\\ 1\end{pmatrix}\end{aligned} \tag{12.1.38}$$

Therefore taking the norm:

$$\|\vec{b}\|=mr^2(t)\dot{\theta}(t)=mr^2(t)\dfrac{\mathrm{d}\theta}{\mathrm{d}t} \tag{12.1.39}$$

And since it is equal to a constant, it is often customary to write this last equality in a condensed form (and putting the mass in the constant):

$$r^2(t)\dfrac{\mathrm{d}\theta}{\mathrm{d}t}=c^{te} \tag{12.1.40}$$

Also, remember that we also got the result that the movement is and remains in a plane without any outside action!

We note also that this law gives us the speed of the planet is variable on its orbit. It is larger at perihelion than at the aphelion:

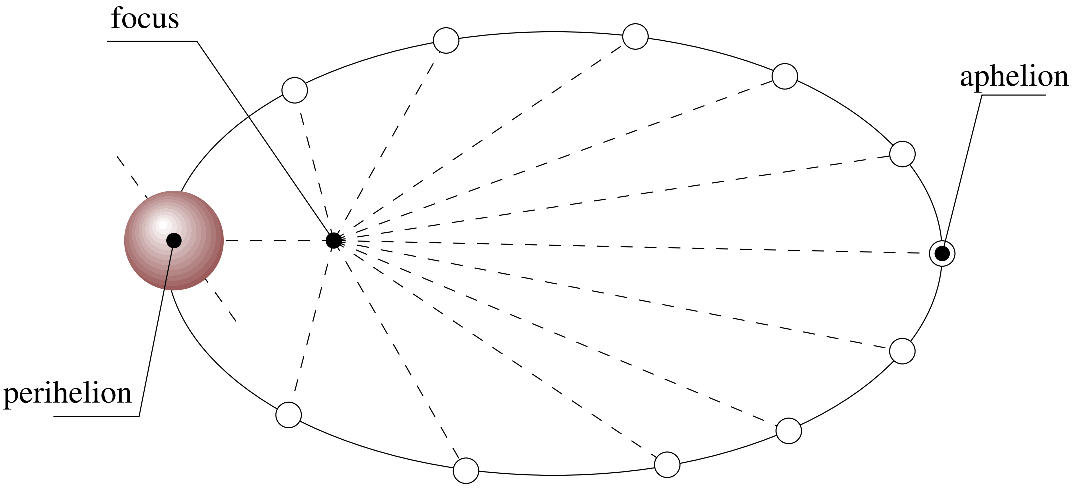

Figure 12.5: **Representation of surfaces conservation**

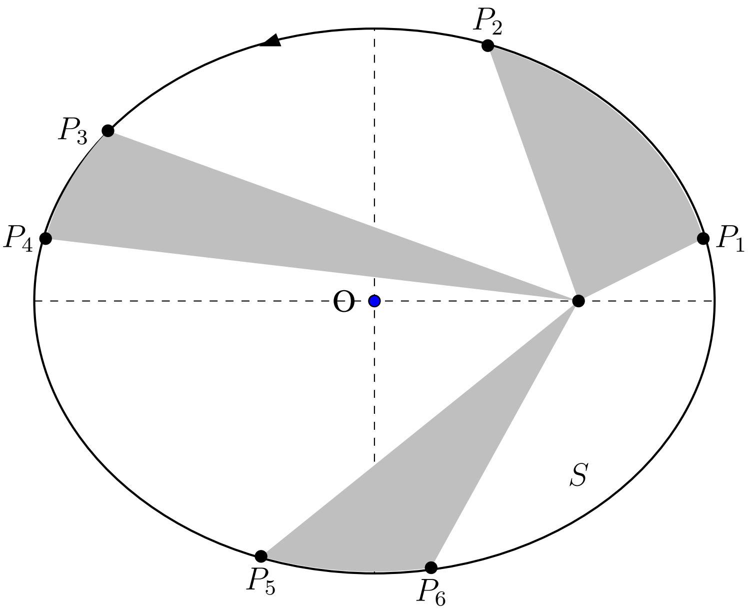
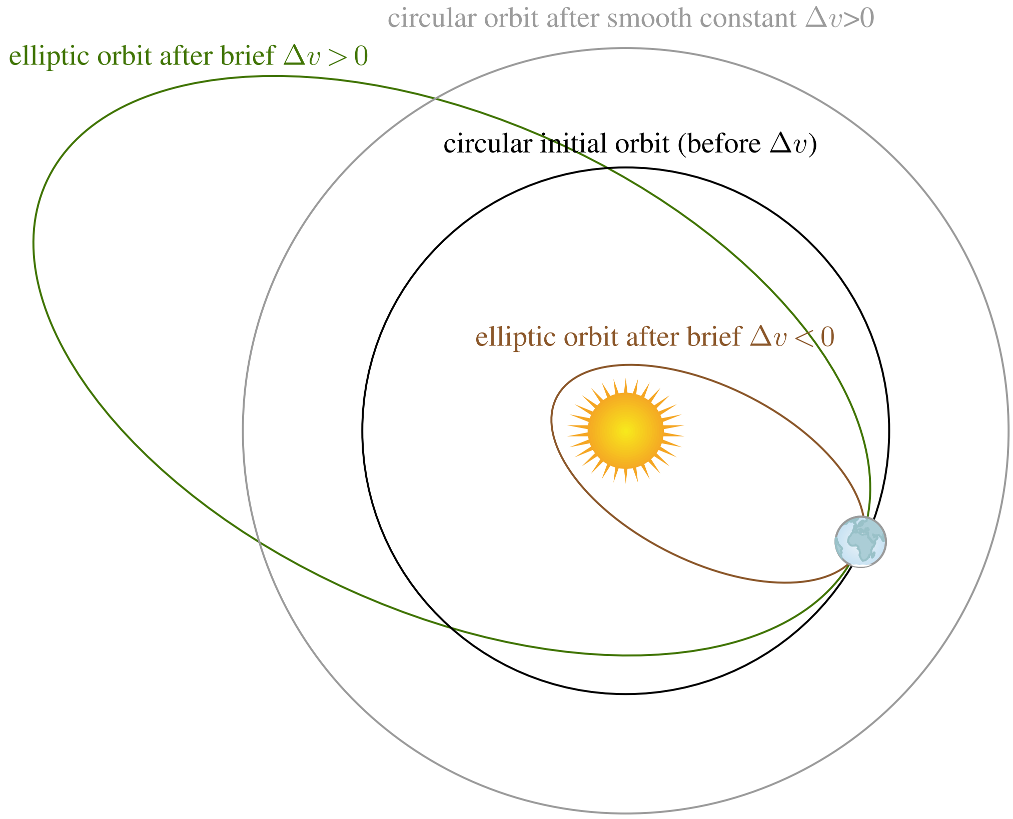
This is true for the Earth for example (for modern measurements of Earth's speed orbit and variation in its orbital speed see [27]). Indeed, this latter is closer to the Sun in winter (for northern hemisphere) and then has a trajectory speed slightly higher than in summer; the travel time is therefore lower (winter has fewer days than the other seasons).

The above figure is often represented in textbooks as:



The second law is the best law to understand what happens in the case where you have an object in equilibrium in orbit and you force quite brutally and temporary a Δv! Indeed, if you imagine an object in a perfect circular orbit and decelerate it quite brutally (with boosters for example), then to sill respect the area law the orbit of the object will have to change from a circular orbit to an elliptic one (but by staying tangential to the point where the Δv has occurred) as illustrated below:



circular orbit after smooth constant Δv>0
elliptic orbit after brief $\Delta v > 0$
circular initial orbit (before Δv)
elliptic orbit after brief $\Delta v < 0$

However the reader must keep in mind that as we will prove it further below during our study of orbital speed at page 5282, at equilibrium the speed is inversely proportional to the square root of the orbital radius (hence the further away an object orbits, the slower it is!):

$$v_{\text{orb.}} = \sqrt{\frac{GM}{R}} \tag{12.1.41}$$

For more about orbits transfer the reader can refer to the section of Aerospace Engineering at page 8633.

12.1.3.2.1 Acceleration variation on an elliptic orbit

The Earth's angular momentum, with respect to the focus of the ellipse, is :

$$b = Mr^2\dot{\phi} \tag{12.1.42}$$

where m, r and $\dot{\phi}$ are the mass, the distance to the center of the Sun and the angular velocity, respectively. Therefore:

$$Mr_p^2\dot{\phi}_p = Mr_a^2\dot{\phi}_a \tag{12.1.43}$$

where the indices p and a denotes "perihelion" and "aphelion". For an ellipse (see section Analytical Geometry page 2775):

$$r_p = \frac{r_0}{1+e} \qquad r_a = \frac{r_0}{1-e} \tag{12.1.44}$$

Hence:

$$\frac{\dot{\phi}_p}{\dot{\phi}_a}=\left(\frac{1+e}{1-e}\right)\cong 1.0340 \tag{12.1.45}$$

since the Earth's orbit eccentricity is, $e\cong 0.0167$. We have a change of about three per cent in six months. The mean angular acceleration is therefore:

$$\bar{\alpha}\cong\frac{0.0340\cdot\phi_a}{180\cdot 24\cdot 60\cdot 60}\cong 10^{-9}\phi_a\,[\text{rad}\cdot\text{s}^{-2}] \tag{12.1.46}$$

Notice that $\dot{\phi}_a$ is of the order of:

$$\frac{2\pi}{365\cdot 24\cdot 60\cdot 60}\cong 10^{-7}\,[\text{rad}\cdot\text{s}^{-1}] \tag{12.1.47}$$

So the angular acceleration is of the order of $10^{-16}\,[\text{rad}\cdot\text{s}^{-2}]$. This is too small to be sensible for humans and also for actual accelerometers.

By the way, if we multiply this value by the actual mean distance to the Sun, $r\cong 10^{11}\,[\text{m}]$, we get an acceleration of order $10^{-6}\,[\text{m}\cdot\text{s}^{-2}]$. That is negligible compared to the acceleration due to the Earth's gravity, $9.81\,[\text{m}\cdot\text{s}^{-2}]$.

12.1.3.2.2 Time of flight

We propose now to apply the second Kepler's law to determine the time t from the passage to the perihelion as a function of the "eccentric anomaly" φ in the case of an elliptic orbit (thus special case!) using its two foci (one of them being assimilable for example to the position of the Sun) and the origin of the "auxiliary circle" (also named "apsidal circle"):

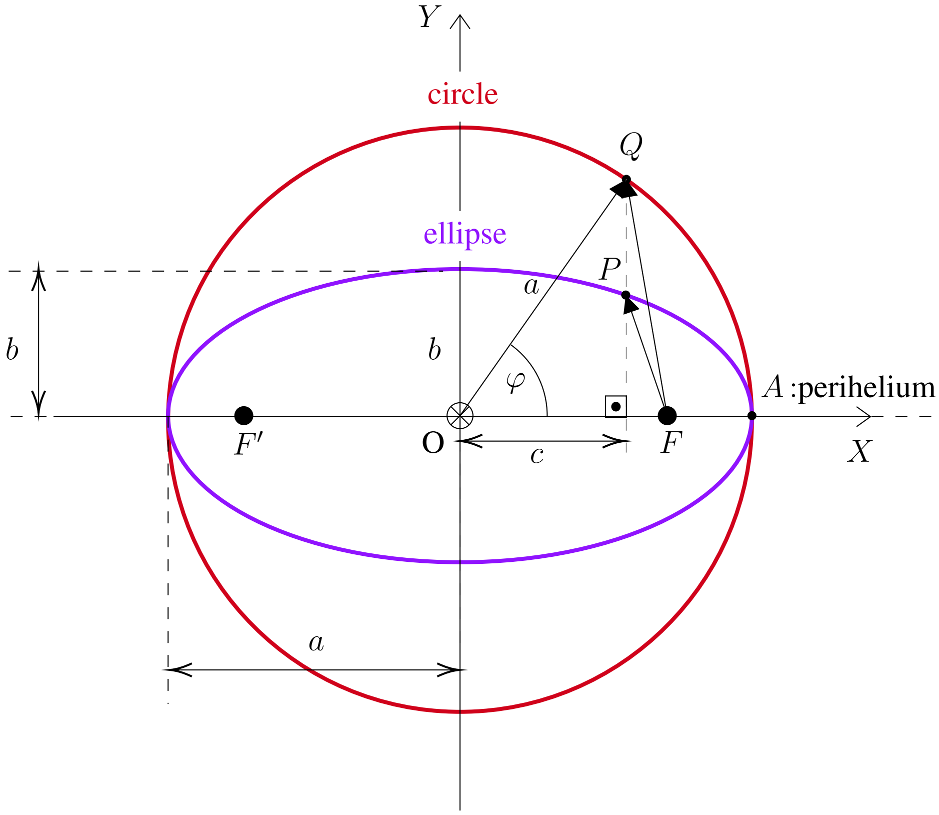


Figure 12.6: **Schema for the study of eccentric anomaly angle**

To determine the time t between the passage at the perihelion A and the point P of a body following the trajectory of the ellipse of surface πab (see the section Geometric Shapes at page 2920 for the proof of the calculation of the surface of the ellipse) in function of the eccentric anomaly φ, we will use the areas law just proved earlier above (second Kepler's law) that gives us the right to write:

$$\frac{S_{AFP}}{t_{\text{flight}}}=\frac{\pi ab}{T} \tag{12.1.48}$$

But, the surface of the ellipse is an affine transformation of the surface of the auxiliary circle such that:

$$S_{\text{ellipse}}=\frac{b}{a}S_{\text{circle}}=\frac{b}{a}(\pi a^2)=\pi ab \tag{12.1.49}$$

We have then:

$$\frac{S_{AFP}}{t_{\text{flight}}}=\frac{\frac{b}{a}S_{AFQ}}{t_{\text{flight}}}=\frac{\frac{b}{a}\left[S_{AOQ}-S_{FOQ}\right]}{t_{\text{flight}}} \tag{12.1.50}$$

If φ is, as it should, expressed in radians, we have of course:

$$S_{AOQ}=a^2\frac{\varphi}{2} \tag{12.1.51}$$

Therefore:

$$\frac{S_{AFP}}{t_{\text{flight}}}=\frac{\frac{b}{a}S_{AFQ}}{t_{\text{flight}}}=\frac{\frac{b}{a}\left[a^2\frac{\varphi}{2}-S_{FOQ}\right]}{t_{\text{flight}}} \tag{12.1.52}$$

For S_{FOQ}, we have $\overline{FO}=a$ therefore equal to the radius of the auxiliary circle. The surface of the triangle S_{FOQ}, knowing its height given by $h=a\sin(\varphi)$ is then obtained by:

$$S_{FOQ}=\frac{1}{2}ch=\frac{1}{2}ca\sin(\varphi) \tag{12.1.53}$$

Therefore we have:

$$\frac{S_{AFP}}{t_{\text{flight}}}=\frac{\frac{b}{a}S_{AFQ}}{t_{\text{flight}}}=\frac{\frac{b}{a}\left[a^2\frac{\varphi}{2}-\frac{1}{2}ca\sin(\varphi)\right]}{t_{\text{flight}}}=\frac{\frac{ab}{2}\left[\varphi-\frac{c}{a}\sin(\varphi)\right]}{t_{\text{flight}}} \tag{12.1.54}$$

But, by definition of the eccentricity (see section Analytical Geometry page 2775), we can write:

$$\frac{S_{AFP}}{t_{\text{flight}}}=\frac{\frac{ab}{2}\left[\varphi-e\sin(\varphi)\right]}{t_{\text{flight}}} \tag{12.1.55}$$

Finally, we have:

$$\frac{\frac{ab}{2}\left[\varphi-e\sin(\varphi)\right]}{t_{\text{flight}}}=\frac{\pi ab}{T} \tag{12.1.56}$$

Therefore:

$$\boxed{t_{\text{flight}}=\frac{\varphi-e\sin(\varphi)}{2\pi}T} \tag{12.1.57}$$

where the angle taken at the center of the ellipse is for recall named the "eccentric anomaly".

Definition (#12.1.525): In the description of the Keplerian orbit of a celestial object, the "eccentric anomaly" is the angle between the direction of the periapse and the current position of an object in its orbit, projected on the circle extinct perpendicular to the major axis of the ellipse

What would interest us now would be to find a relation of passage between this eccentric anomaly and the angle named "true anomaly" θ as sometimes it is often more advantageous to use this last angle.

For a relation between the eccentric anomaly φ and the true anomaly θ, we will reuse our above schema but modified a bit:

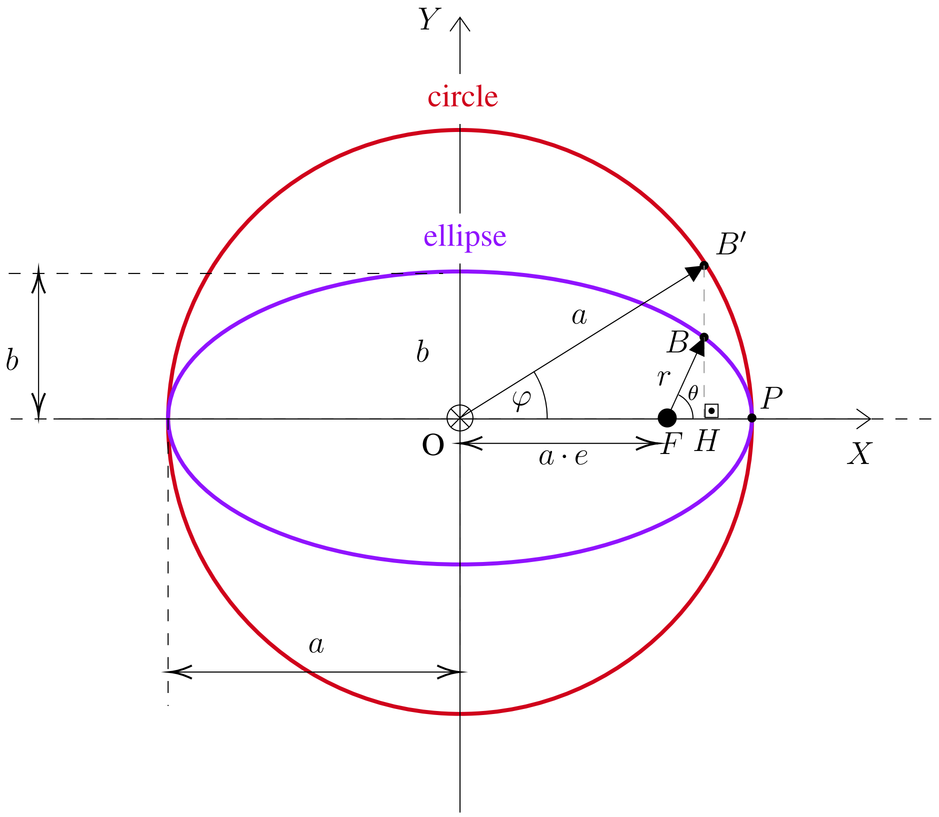

Figure 12.7: **Schema for the study of true-eccentric anomaly angle relation**

We have obviously the 4 below relations which a deduce from the above figure:

$$\begin{aligned}r\cos(\theta)&=\overline{FH}\\ r\sin(\theta)&=\overline{HB}\\ a\cos(\varphi)&=\overline{\text{O}H}\\ a\sin(\varphi)&=\overline{HB'}\end{aligned} \tag{12.1.58}$$

We then have already in a first time (relation which will be useful to us a little later):

$$r\cos(\theta)=\overline{FH}=\overline{\text{O}H}-\overline{\text{O}F}=a\cos(\varphi)-ae \tag{12.1.59}$$

We have also proved in the section of Analytical Geometry that (see page 2779):

$$\frac{b}{a}=\sqrt{1-e^2} \tag{12.1.60}$$

this relation being valid at any border point of the ellipse. Thus, we also have:

$$\frac{\overline{HB}}{\overline{HB'}}=\sqrt{1-e^2}=\frac{r\sin(\theta)}{a\sin(\varphi)} \tag{12.1.61}$$

Which leads us to write:

$$\sin(\theta)=\frac{a\sin(\varphi)\sqrt{1-e^2}}{r} \tag{12.1.62}$$

Ideally, we could get rid of the radius in the denominator. For this, we will use the fact that (relations that we have just proved earlier above):

$$\begin{aligned}r\sin(\theta)&=a\sin(\varphi)\sqrt{1-e^2}\\ r\cos(\theta)&=a\cos(\varphi)-ae\end{aligned} \tag{12.1.63}$$

We have:

$$r^2\sin^2(\theta)+r^2\cos^2(\theta)=a^2\sin^2(\varphi)\left(\sqrt{1-e^2}\right)^2+(a\cos(\varphi)-ae)^2 \tag{12.1.64}$$

The terms to the left of the equality are simplified immediately:

$$\begin{aligned}r^2&=a^2\sin^2(\varphi)\left(\sqrt{1-e^2}\right)^2+(a\cos(\varphi)-ae)^2\\ &=a^2\left[\sin^2(\varphi)(1-e^2)+\cos^2(\varphi)-2e\cos(\varphi)+e^2\right]\\ &=a^2\left[\sin^2(\varphi)-e^2\sin^2(\varphi)+\cos^2(\varphi)-2e\cos(\varphi)+e^2\right]\\ &=a^2\left[1-e^2\sin^2(\varphi)-2e\cos(\varphi)+e^2\right]\\ &=a^2\left[1-e^2(1-\cos^2(\varphi)-2e\cos(\varphi)+e^2\right]\\ &=a^2\left(1+e^2\cos^2(\varphi)-2e\cos(\varphi)\right)=a^2(1-e\cos(\varphi))^2\end{aligned} \tag{12.1.65}$$

hence:

$$r=a(1-e\cos(\varphi)) \tag{12.1.66}$$

therefore:

$$\sin(\theta)=\frac{a\sin(\varphi)\sqrt{1-e^2}}{a(1-e\cos(\varphi))}=\frac{\sin(\varphi)\sqrt{1-e^2}}{1-e\cos(\varphi)} \tag{12.1.67}$$

thus finally:

$$\boxed{\theta=\arcsin\left(\frac{\sin(\varphi)\sqrt{1-e^2}}{1-e\cos(\varphi)}\right)} \tag{12.1.68}$$

Finally notice that in the special case of an elliptical orbit, we deduce thanks to the second Kepler's law (see the proof of the calculation of an area of an ellipse in the section Geometric Shapes page 2917) the:

12.1.3.3 Third Kepler's Law (periods' law)

The "Kepler's third law", sometimes also named "Periods' law" or "Kepler's harmonic law", is stated as follow: The squares of the periods of revolution T are proportional to the cube of the semi-major axes of the orbits D:

$$T^2=c^{te}D^3 \Leftrightarrow \frac{T^2}{D^3}=c^{te} \tag{12.1.69}$$

The last ratio is then a constant in practice for all planets (in physics we also speak of "invariant") and the reason for this "harmony" was difficult to explain before Newton's theory.

Again, we will see later that the status of "law" is no longer justified in our time as it is possible to prove that this relation, whose expression will be detailed, is in reality:

$$\frac{R^3}{T^2}=\frac{Gm}{4\pi^2}=c^{te} \tag{12.1.70}$$

and therefore we understand better when we see the term on the right why we had the previous constant (m is the central body mass!).

The last relation is more often written as following in the field of astronomy:

$$\boxed{\frac{a^3}{T^2}=\frac{GM}{4\pi^2}=c^{te}} \tag{12.1.71}$$

where as we have seen in the section of Analytical Geometry, a is the traditional notation for the semi major axis of ellipse. It is important to notice that whatever the magnitude of the semi minor axis, if the semi major axis of multiple ellipses are identical, their periods (and therefore the corresponding total energy) will be identical.

The most commonly used rearrangement of this last relation is obviously:

$$T=\sqrt{\frac{a^3 4\pi^2}{GM}}=2\pi\sqrt{\frac{a^3}{GM}} \tag{12.1.72}$$

Of course, Kepler did not immediately published his three laws in this provocative simplicity. Their current presentation order is also not the original one ... They are in reality to find among a profusion of physical speculations and reflections on world's harmony.

Remark

The Kepler's law are not limit to the gravitation force. They also apply for all acceleration (or force) of the type $1/r^2$. And this is also the case of the Coulomb's law (see section Electrostatics page 3968). Kepler's law can therefore also be applied to an electron in orbit around a nucleus. The Wilson and Sommerfeld model (see section Quantum Corpuscular Physics page 4644) based also on Kepler's law gives also elliptic trajectories for electrons!

Here is an high definition image (you can zoom in a lot!) with some celestial bodies of the Solar System, and for many of them, their orbital period T and their distance a to their main attractor:

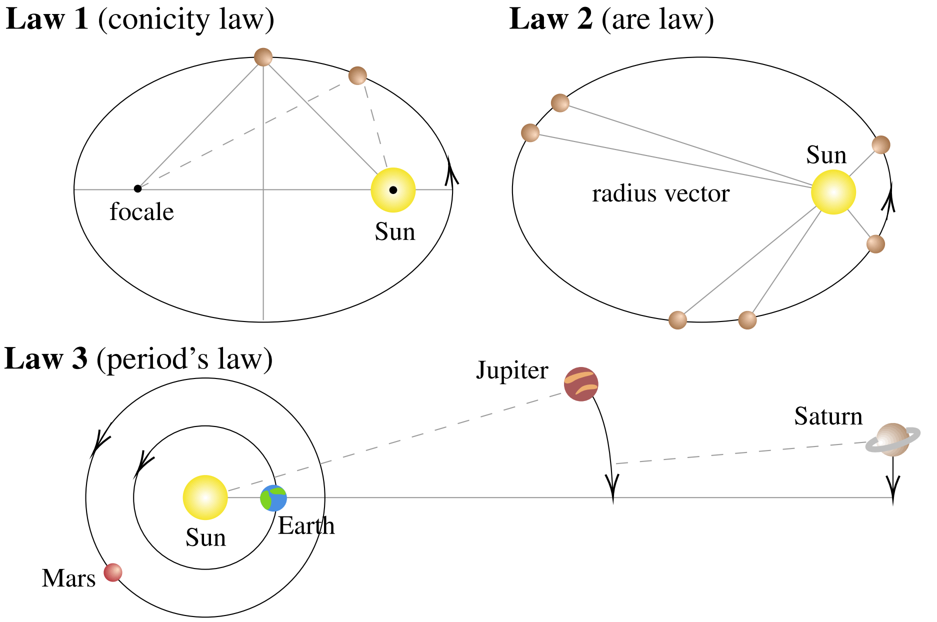
Figure 12.10: **Side by side planets and dwarf planets (source: ?)**

For information, the rotation of Earth's on itself slows down at the day we write these lines of approximately 2.3 milliseconds per century. That means 1 hour every 180 millions years. Each year the Earth's orbit speed around the Sun (actually a G2V-type star, aka yellow dwarf) also slows down of approximately 3 nanometers-per-second. Using Kepler's law, that means that the Earth goes further away from the Sun of 3 micrometers per 1 billion year......!!!!

The three Kepler's law can then be summarized by the following small figure:



Law 1 (conicity law)
focale
Sun
Law 2 (are law)
Sun

Mars

$$\frac{P^2}{a^2}=\overset{\text{Earth}}{\frac{(1)^2}{(1)^2}}=\overset{\text{Mars}}{\frac{(1.88081)^2}{(1.52369)^2}}=\overset{\text{Jupiter}}{\frac{(11.86179)^2}{(5.2028)^2}}=\overset{\text{Saturn}}{\frac{(29.4556)^2}{(9.53884)^2}}$$

Figure 12.11: **Summary of Kepler's laws illustrated**

The reader must take precautions with the image above because:

1. The planets are most of time in a movement that is not in the same plane. For the Solar System it is the tradition at high school level to represent the planets in the "ecliptic" plane that is the average plane described by the movement of Jupiter around the Sun:

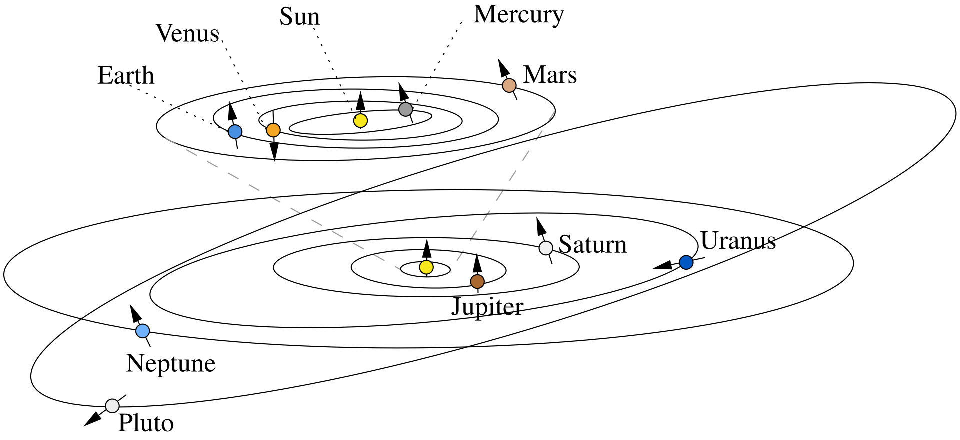

Figure 12.12: **Planets spin and angle relatively to the ecliptic plane**

2. The orbits precess around the Sun (actually a G2V-type star, aka yellow dwarf) as shown in the following figure (see further below for the mathematical proof in the case of a 2-body system):

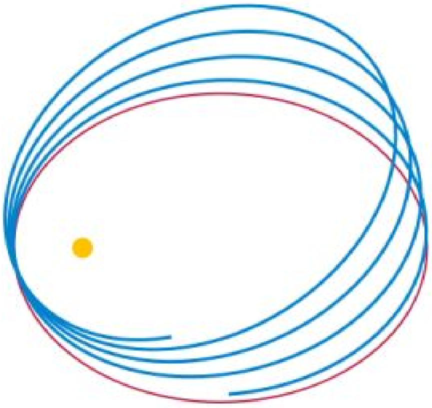

Figure 12.13: **Orbit precession example**

3. The planets have an helical trajectory "behind" the movement of the Sun around the center of our Galaxy[5] and the ecliptic has an angle of approximately 60° ($\pi/3$ [rad]) relatively to the perpendicular of the Sun movement as visible in the figure below:

---

[5] The velocity of the Sun around the galactic center is named the "galactic orbital motion" and there is a systematic review (see [554]) of 42 different methods from more than 30 studies and as many independent teams that lead to an actual median of 232 $[\text{km}\cdot\text{s}^{-1}]$ and a mean weighted value at one sigma of 228 ± 2; $[\text{km}\cdot\text{s}^{-1}]$.

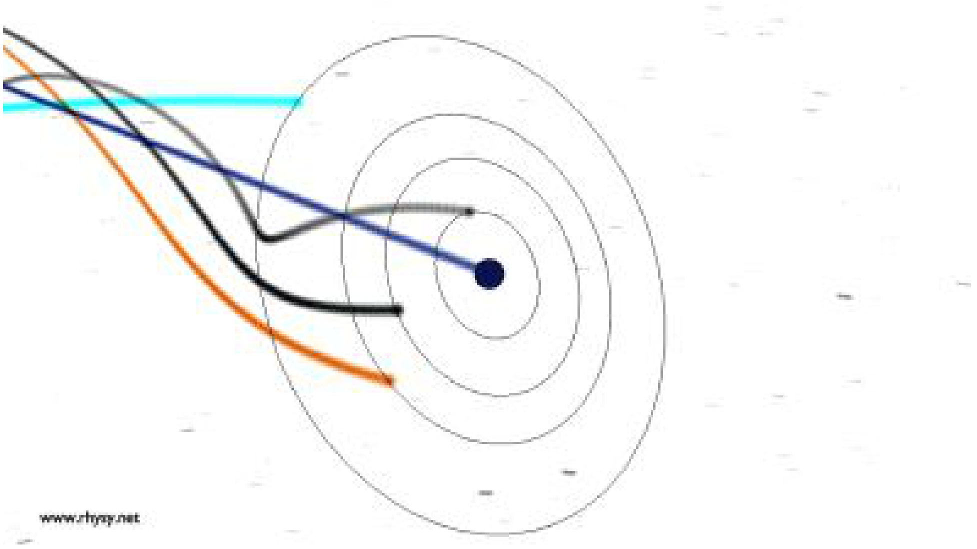

Figure 12.14: Schematic view of planets falling behind the Sun in its movement

and the planets are therefore sometimes in front of the Sun (actually a G2V-type star, aka yellow dwarf) and sometimes behind. Below is a prettier view rendered with a computer:

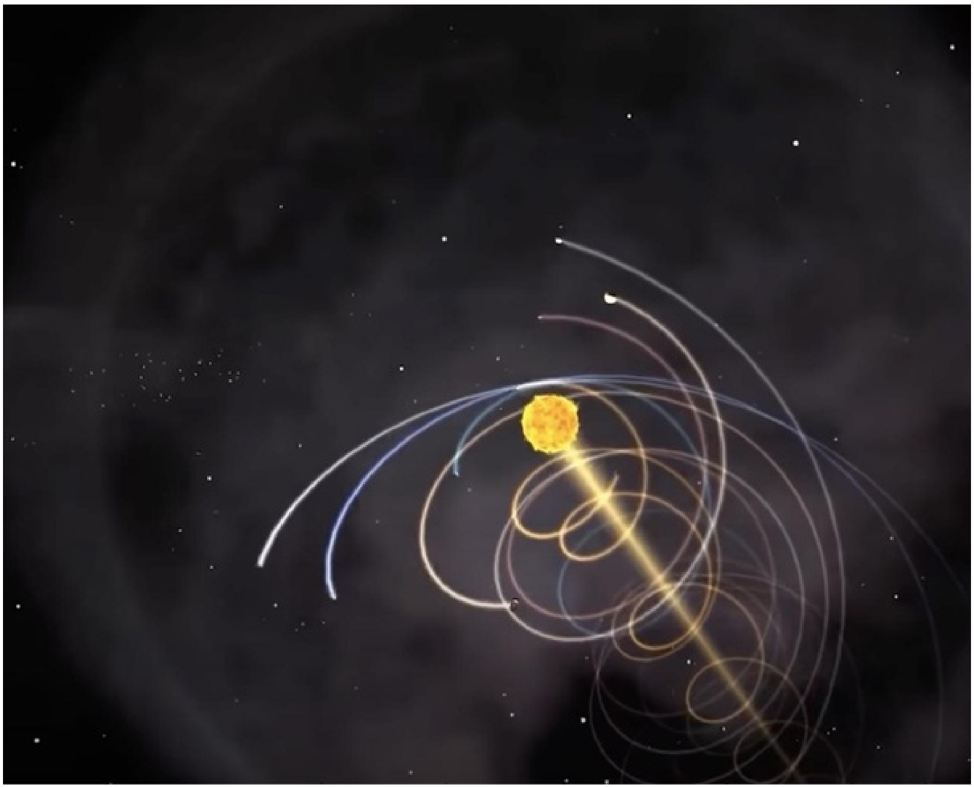

Figure 12.15: Computer rendered view of planets falling behind the Sun in its movement

Because of the movement of our Sun around the center of our Galaxy and some far-distant interactions in-between other celestial objects, the reader must understand that constellations doesn't appear always as there are today (this is named the "secular parallax")! The geometry changes and even on the very long term... some stars of the constellations may disappear (as they have a finished lifetime!):

Figure 12.18: The Latin astrolabe's "rete" from the Musée des Arts précieux Paul-Dupuy (Toulouse, France) with its 34 pointers (blue) and the reference stars (red) most closely aligned with it nowadays (source: [130])

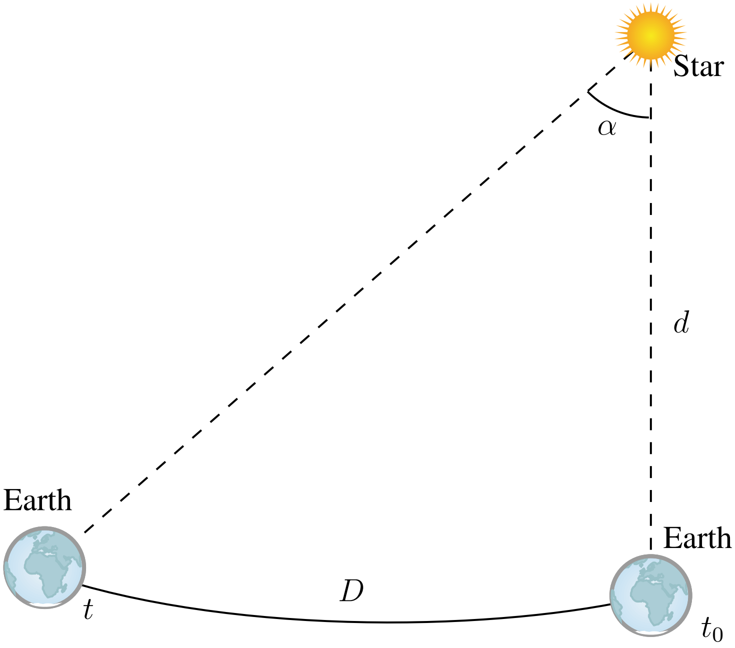
For example, the distance from Earth to Betelgeuse is of approximately $d = 6.07 \cdot 10^{18}$ [m]. Let us consider at time t_0 where this distance has been measured. Now, our Solar

System - Earth and all - whirls around the center of our Galaxy at some 220 kilometres per second. Hence after 100 year, Earth's have moved away from it's initial position (relatively to the galactic center) at t_0 of:

$$D=(100\cdot 365\cdot 24\cdot 60\cdot 60)\cdot(220\cdot 10^3)\cong 694\cdot 10^{14}\,[\text{m}] \tag{12.1.73}$$

Which corresponds to a variation of angle (parallax) between position at time t_0 and position at time t of (see the idea in the figure below that is obviously not to scale...):

$$\alpha\cong\arctan\left(\frac{D}{d}\right)=\arctan\left(\frac{694\cdot 10^{14}}{6.07\cdot 10^{18}}\right)\cong 0.006^\circ \tag{12.1.74}$$



For Proxima Centauri, the closest star to our own, the same calculation leads to:

$$\alpha=\arctan\left(\frac{694\cdot 10^{14}}{8.231\cdot 10^{16}}\right)\cong 0.988^\circ \tag{12.1.75}$$

This is obviously an upper value because in reality most of the stars in our night sky move with us in the galactic arm in the same direction!

Not only apparent relative distances between stars within a constellation (and every other star!) changes over time but also the absolute distance between them and Earth is in reality an illusion that also changes over time !! For example at naked eye Orion's constellation stars may seem all lying in an identical plane (and at a human scale life not moving...):

This is how the Universe is! A giant (very likely infinite) mess where the huge majority of stuff is dynamic and interacts to generate/destruct other stuff throughout time.

4. On the very very long term the orbits in a n-body system is a chaotic deterministic system that has period of quasi-stability but that sometimes diverges completely. This is great opportunity at the date we write these lines to be in such a period of quasi-stability.

Remark

The n-body problem considers n point masses $m_i, i = 1, 2, \ldots, n$ in an inertial reference frame in three dimensional space $\mathbb{R}^3$ moving under the influence of mutual gravitational attraction. Each mass m_i has a position vector $\vec{r}_i$. Newton's second law says that mass times acceleration $m_i \frac{\mathrm{d}^2\vec{r}_i}{\mathrm{d}t^2}$ is equal to the sum of the forces on the mass. Newton's law of gravity says that the gravitational force felt on mass m_i by a single mass m_j is given by:

$$\vec{F}_{ij} = \frac{Gm_i m_j}{\|\vec{r}_j - \vec{r}_i\|^2} \cdot \frac{(\vec{r}_j - \vec{r}_i)}{\|\vec{r}_j - \vec{r}_i\|} = \frac{Gm_i m_j\,(\vec{r}_j - \vec{r}_i)}{\|\vec{r}_j - \vec{r}_i\|^3} \tag{12.1.76}$$

where G is the gravitational constant and $|\vec{r}_j - \vec{r}_i|$ is the magnitude of the distance between $\vec{q}_i$ and $\vec{q}_j$ (metric induced by the L_2 norm). Summing over all masses yields the "n-body equations of motion":

$$\boxed{m_i \frac{\mathrm{d}^2\vec{r}_i}{\mathrm{d}t^2} = \sum_{\substack{j=1\\ j\neq i}}^{n} \frac{Gm_i m_j\,(\vec{r}_j - \vec{q}_i)}{\|\vec{r}_j - \vec{r}_i\|^3} = -\frac{\partial U}{\partial \vec{r}_i}} \tag{12.1.77}$$

where U is the self-potential energy.

Some very typical very simple empirical evidence that the Earth rotates around the Sun (barycenter Earth-Sun to be exact) and not the opposite are:

1. The apparent position of stars close to earth (like Alpha Centauri) changes relative to stars much much further away (star parallax).
2. The retrograde motion of planets as seen from the Earth is incompatible with a geocentric system.
3. The fact that old astrolabs show that the shape of constellations has changed means that the Earth move and is not fixed or respectively that the stars themselves are not fixed like the Barnard's star whose movement can easily been seen (or obviously both!).
4. Galileo observed that Venus goes through a full set of phases, similar to the Moon. This can only happen if Venus orbits the Sun, which in turn implies that Earth does as well.

> *The Earth is not fitted to us, we are fitted to the Earth.*

quote 12.1:5251.#68

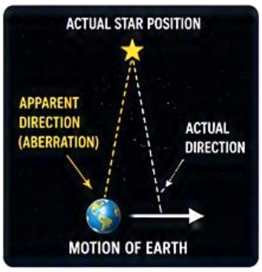
EARTH MOVES IN SPACE

Centuries of observations, experiments, and measurements from many fields of science all tell the same story: Earth is in motion.

1 STELLAR ABERRATION

Because Earth moves through space, starlight appears to come from a slightly forward direction—the same way raindrops seem to slant backward when you walk forward.

Measured and explained by James Bradley in 1728.

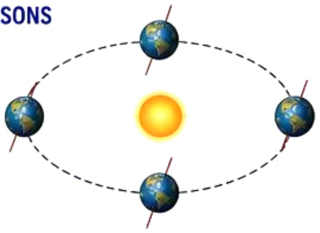


ACTUAL STAR POSITION
APPARENT DIRECTION (ABERRATION)
ACTUAL DIRECTION
MOTION OF EARTH

2 THE YEAR AND SEASONS

Earth orbits the Sun once every ~365.25 days.

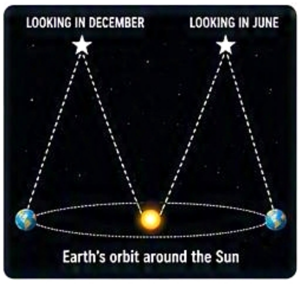
The tilt of Earth's axis (23.5°) as it orbits the Sun causes the changing seasons.



3 STELLAR PARALLAX

As Earth orbits the Sun, nearby stars appear to shift position against distant background stars over 6 months.

This effect can only be explained by Earth's motion.

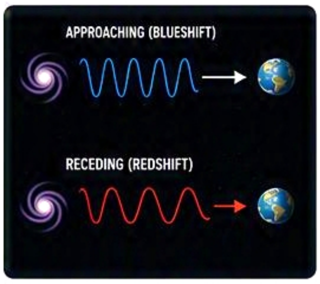


LOOKING IN DECEMBER
LOOKING IN JUNE
Earth's orbit around the Sun

4 DOPPLER SHIFT

When Earth moves toward a source of light or radio waves, the waves are blueshifted (shorter wavelength). When moving away, they are redshifted (longer wavelength).

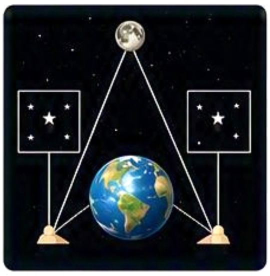
This is observed for stars, galaxies, and other celestial objects.



APPROACHING (BLUESHIFT)
RECEDING (REDSHIFT)

5 PARALLAX OF THE MOON

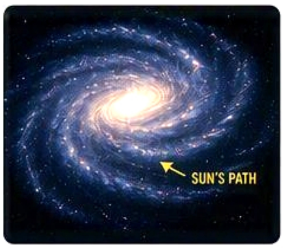
Observing the Moon from different locations on Earth at the same time shows it against the background stars from slightly different angles.
This proves Earth is large, round, and the Moon is relatively close —consistent with Earth's motion in space.



6 MOTION OF THE SOLAR SYSTEM THROUGH THE MILKY WAY

The Sun (and Earth) orbits the center of the Milky Way once about every 225–250 million years.

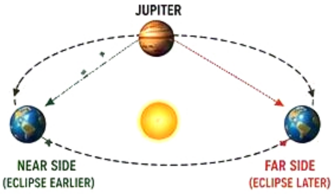
This is revealed by the motion of stars, gas clouds, and the cosmic microwave background.



7 SIGNAL DELAY & PULSAR TIMING (RØMER DELAY)

Ole Rømer demonstrated that the eclipses of Jupiter's moon Io occurred about 16.6 minutes earlier when Earth was on the near side of its orbit relative to Jupiter compared to when it was on the far side.

This time difference represents the time required for light to travel across the diameter of Earth's orbit.

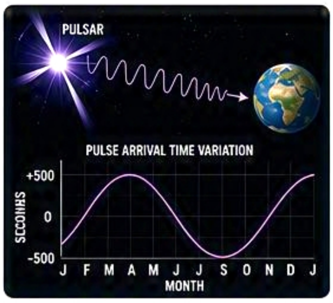


JUPITER
NEAR SIDE (ECLIPSE EARLIER)
FAR SIDE (ECLIPSE LATER)

Extra distance for light when Earth is on the far side = ~16.6 minutes

8 PULSAR TIMING

Millisecond pulsars emit radio pulses with extreme regularity. Precise timing models at Earth-based observatories show that pulse arrival times oscillate predictably by up to ±500 seconds throughout the year due to Earth's movement closer to or farther from the pulsar.



9 RETROGRADE MOTION OF PLANETS

Mars, Jupiter, and Saturn sometimes appear to reverse direction and trace loops against the background stars.

This happens when Earth, moving faster on its orbit, overtakes an outer planet. The heliocentric model predicts the timing, shape, and duration of these loops with high precision.

Remark

A "zodiacal constellation" is any constellation (human imaginary figural construction of a group of stars) whose official IAU (International Astronomical Union) boundaries lie along the ecliptic — the apparent yearly path of the Sun — so the Sun, Moon, and planets appear to pass through them; astronomers treat the zodiac as a narrow band roughly a few degrees north and south of the ecliptic rather than as thirteen equal signs.

Actually, in astronomy (not in astrology that is not a Science!), there are thirteen constellations. As they don't have the same size, they obviously don't have the same number of days. For example for the well-know "Western constellations" (yes chinese don't have the same for example...) also referred to as "tropical astrology", we have:

Constellation	**Approximate days spent**	**Approximate angular size along ecliptic**
Pisces (Fishes)	38 days	37.5°
Aries (Ram)	25 days	24.7°
Taurus (Bull)	37 days	36.5°
Gemini (Twins)	31 days	30.5°
Cancer (Crab)	20 days	19.7°
Leo (Lion)	37 days	36.5°
Virgo (Maiden)	45 days	44.4°
Libra (Scales)	23 days	22.7°
Scorpius (Scorpion)	7 days	6.9°
Ophiuchus (Serpent Bearer)	18 days	17.8°
Sagittarius (Archer)	32 days	31.5°
Capricornus (Sea-Goat)	28 days	27.6°
Aquarius (Water Bearer)	24 days	23.7°

Table 12.2: **Actual durations and angular sizes of the actual western zodiacal signs**

As the solar system moves and stars also move, the astrological zodiacal dates doesn't correspond anymore to the scientific observed astronomical dates (and the difference will increase as hundreds of thousands or millions of years will pass):

Constellation	Tropical zodiac dates	IAU boundaries
Aries	Mar 21 - Apr 19	Apr 18 - May 13
Taurus	Apr 20 - May 20	May 13 Jun 21
Gemini	May 21 - Jun 20	Jun 21 - Jul 20
Cancer	Jun 21 - Jul 22	Jul 20 - Aug 10
Leo	Jul 23 - Aug 22	Aug 10 Sep 16
Virgo	Aug 23 - Sep 22	Sep 16 - Oct 30
Libra	Sep 23 - Oct 22	Oct 30 - Nov 23
Scorpio	Oct 23 - Nov 21	Nov 23 - Nov 29
Ophiuchus	-	Nov 29 - Dec 17
Sagittarius	Nov 22 - Dec 21	Dec 17 - Jan 20
Capricorn	Dec 22 - Jan 19	Jan 20 - Feb 16
Aquarius	Jan 20 - Feb 18	Feb 16 - Mar 11
Pisces	Feb 19 - Mar 20	Mar 11 - Apr 18

Table 12.3: **Astrological western zodiacal dates vs Scientific western zodiacal dates (as in 121th century according to holocene calendar)**

12.1.4 Newton's Gravitational Law

To check the accuracy of his hypothesis, Newton (relatively long after Kepler) found Kepler's laws from the law of gravity, giving the explanation of the general movement of the planets.

Newton considered to determine the law of gravitation a theoretical planet orbiting around the Sun (actually a G2V-type star, aka yellow dwarf) in a circular orbit at a constant speed v. During a complete orbit the planet travels a distance equal to the circumference of the circle of radius R, or $2\pi R$, in a time (the period) equal to the distance divided by its velocity, either:

$$T=\frac{2\pi R}{v} \tag{12.1.78}$$

Newton then relies on the third Kepler's law with always the assumption of a circular orbit.

We therefore have:

$$T^2=c^{te}R^3 \tag{12.1.79}$$

but as:

$$T=\frac{2\pi R}{v} \tag{12.1.80}$$

Then we get by substitution:

$$T^2=4\pi^2\frac{R^2}{v^2} \tag{12.1.81}$$

By comparing:

$$T^2=c^{te}R^3 \tag{12.1.82}$$

and:

$$T^2=4\pi\frac{R^2}{v^2} \tag{12.1.83}$$

and now assuming that $4\pi^2$ is divided by the constant is a new constant (which will be denoted in the same manner as the first although it is not equal to...) we get:

$$R^3=\frac{4\pi^2}{c^{te}}\frac{R^2}{v^2}=c^{te}\frac{R^2}{v^2} \tag{12.1.84}$$

Therefore:

$$R^2=c^{te}\frac{R}{v^2} \tag{12.1.85}$$

Then, if we reverse the terms, this expression becomes (while noting that the inverse of the original is constant is, also, a constant):

$$\frac{1}{R^2}=c^{te}\frac{v^2}{R} \tag{12.1.86}$$

By another calculation, we have already established in the section of Classical Mechanics (see page 3388) the expression of centrifugal (fictional) force:

$$F_{\text{cent}} = m\frac{v^2}{R} \qquad (12.1.87)$$

by comparing this expression with the previous one:

$$\frac{1}{c^{te}}\frac{1}{R^2} = \frac{v^2}{R} \qquad (12.1.88)$$

we get:

$$F_{\text{cent}} = m\frac{v^2}{R} = m\frac{1}{c^{te}}\frac{1}{R^2} = \frac{mc^{te}}{R^2} = F_G \qquad (12.1.89)$$

There should therefore exist a force opposed to the centrifugal (fictional) force that keeps the orbital cohesion and which can be written:

$$F_G = \frac{mc^{te}}{R^2} \qquad (12.1.90)$$

remains to determine the value of the constant!

It is trivial that the central mass M of the orbital system has to intervene in one way or another in this constant. If the mass of the secondary body intervenes proportionally in the centrifugal (fictional) force, the desire is great to do the same with the mass of the central body. So:

$$F_G = \frac{mMc^{te}}{R^2} \qquad (12.1.91)$$

Now there would be a priori more parameters to take into account. The remaining constant is here to meet the dimensional analysis so that we have "Newtons" (name given to the unit of force) on both sides of the equality. Scientists have determined with precision this "gravitational constant" denoted by G that a priori seems universal and which in SI units (as recommended by the 12014 - according to holocene calendar - CODATA[6] with standard uncertainty in parentheses), is:

$$G \cong 6.67408(31) \cdot 10^{-11} \left[\text{N} \cdot \text{m}^2 \cdot \text{kg}^{-2}\right] \qquad (12.1.92)$$

Remark

So far, within the commonly accepted picture G (that can also be expressed in $\left[\text{kg}^{-1} \cdot \text{m}^3 \cdot \text{s}^{-1}\right]$), like light velocity c, has been considered as one of the most fundamental constants of the Universe. Nevertheless, recent theoretical studies suggested that G could be truly expressed as a function of more fundamental physical quantities, i.e. the so named "Quantum Vacuum Zero Point Field Mass - Density Equivalent" ρ_{Qv} giving a measure of the energy density of the QED quantum vacuum (also known as ZPF). If we play with the maths it can be shown (see [83]) that the inverse of G multiplied by c (to get rid of the concept of time and transform it into a dimension of space) is equivalent in units as the amount of vacuum mass density moved on a distance of one meter.

---

[6] Committee on Data for Science and Technology

force needed to displace a cubic metre of vacuum that weighs one kg in one second.

Which brings us to write the two body "Newton's gravitational law":

$$\boxed{F_G = G\frac{mM}{R^2}} \tag{12.1.93}$$

that is a "central force" identically to the electrostatic force! The Newton's gravitational law for a simple three body case problem like the Sun-Earth-Moon system is given in details at page 5498 and is given by:

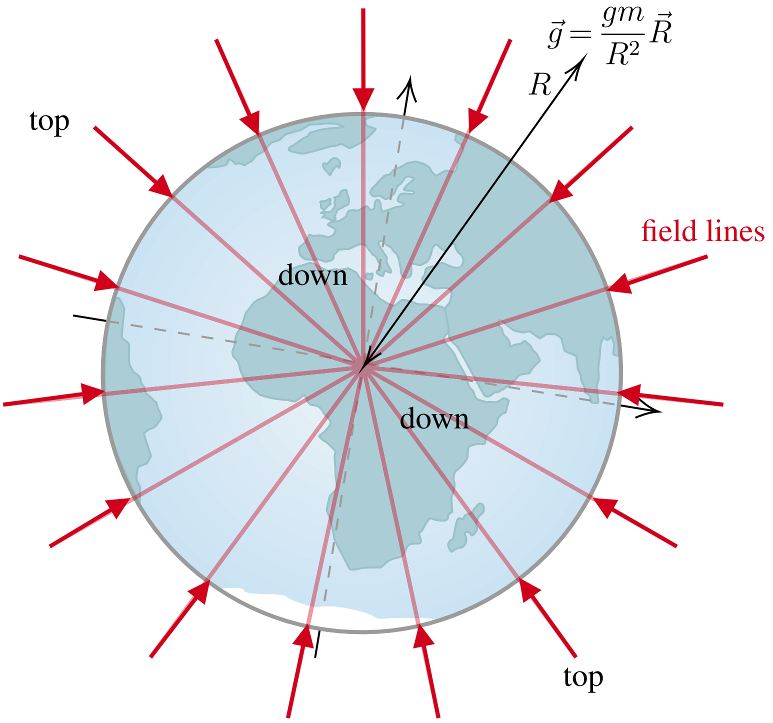
$$m_a\frac{\mathrm{d}^2\vec{r}_a}{\mathrm{d}t^2} = \sum_{b\neq a} Gm_am_b\frac{\vec{r}_b-\vec{r}_a}{|\vec{r}_b-\vec{r}_a|^3} \quad \text{for } a = 1, 2 \text{ and } 3 \tag{12.1.94}$$

Obviously the derivation above is not a true rigorous proof because it is based on experimental Kepler's observations! By cons, from General Relativity (see page 5751) it is possible to prove it (under some given assumptions...), therefore it loss its status as law and becomes a theory!

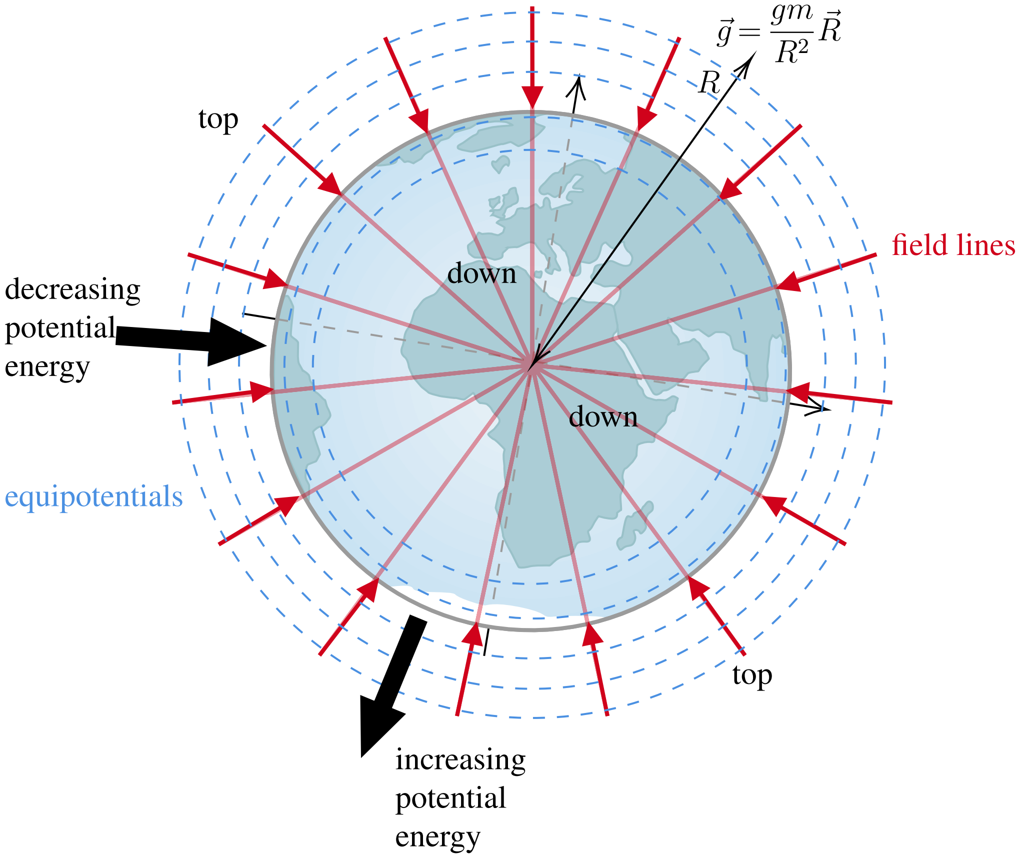
Remark

Newtonian gravity is not local, this bothered Newton a lot back then! You see if you take Newton's law of gravity, with the gravitational force proportional to the mass divided by the square of the distance, then if you move the mass, the distance increases and the force changes instantaneously, everywhere. Newton was greatly bothered by this. He named it "action at a distance" and that's also what Einstein meant by the phrase. Einstein's theory of General Relativity, which we use now to describe gravity, doesn't have this problem. In Einstein's theory, gravity is described by the curvature of space and time. And that curvature is caused by the mass and energy in space-time. If you move the mass that causes space-time to curve, then the curvature changes, but not instantaneously. The change spreads outwards at the speed of light (see section General Relativity page 5861). So, Einstein's theory is "local" as physicists say.

Below we have illustrated how the gravitational field is a central force pointing uniformly to the center of the Earth (similarly to a punctual electric charge):



Because the gravitational field is a central force exactly like the electrostatic field, we get exactly the same kind of mathematical expression and properties for the expression of the work and for the equipotentials (see section Electrostatics page 3980) that are therefore perpendicular to the field lines (obviously the reader should remember that in reality the field lines go to infinity and the equipotentials go from the center of the Earth to infinity too):



$\vec{g} = \frac{gm}{R^2}\vec{R}$
R
top

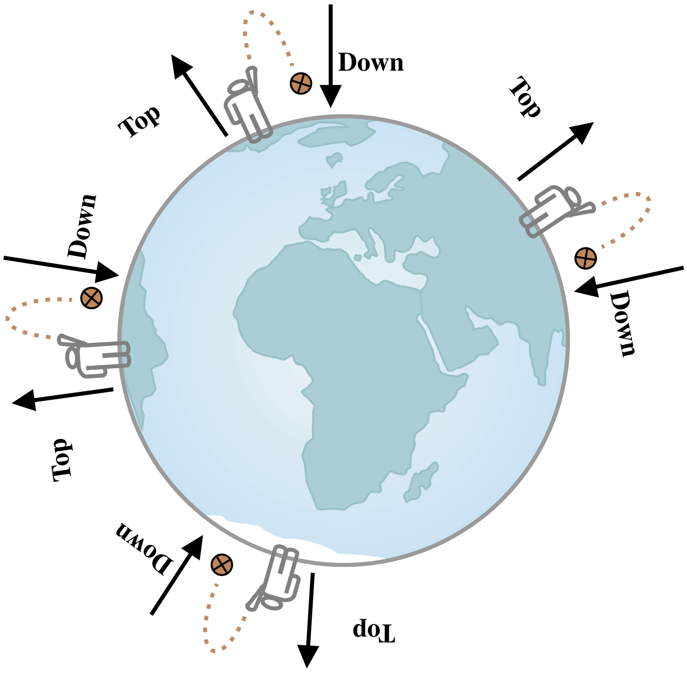
top
increasing potential energy

Figure 12.23: **Gravitational field lines and equipotentials**

Or represented in a more childish way:



Down
Top
Top
Down
Down
Top
Down
Top

Figure 12.24: **Up and Down on a Spherically Symmetrical Planet**

When on Earth (and other planet/massive objects) we say that something goes "downwards" (like water flow for example), it doesn't mean that the thing follows the curvature Earth but that its potential energy decreases by approching the center of the Earth!

Caution! As we will prove it later (result already known at the time of Newton) the three macroscopic spatial dimensions are very special! In particular, in three dimensions gravity obeys an inverse square law, without which stable planetary orbits would not be possible. But keep in mind that since the space-time model is a human invention, so must be the dimensionality of space-time. We choose it to be three because it fits the data. In the M-theory we choose it to be eleven. We use whatever works, but that does not mean reality is exactly that way in one-to-one correspondence.

Definition (#12.1.526): In physics we say that something is "at level", or simply "levelled", when it coincides with a line or surface that cuts perpendicularly all plumb lines (i.e. perpendicular to gravity) that it meets and hence would everywhere coincide with a surface of still water (or any other continuum medium) that follows the gravitational equipotentials, the levelling is typically measured with a gravimeter[7]. The concept of "level" must not be confused with that of "flatness" - in the standard ISO 12781 "flatness" is defined as the distance between the minimum and maximum point of a surface - that is mainly used in mechanics and architecture and measured thanks to a flatness gauge/lap plate (for good precision) or in the worst case with a bubble level.

Remark

The equality:

$$a=G\frac{M}{r^2} \tag{12.1.95}$$

explains the genius intuition of Galileo: that in vacuum (!) a feather and bowling ball will fall at the same speed (i.e. with the same acceleration), as that latter depends only on the main body of attraction that has for mass M. Only the force on the two objects is not the same! But the acceleration is however the same!

Now some reader may think that there is a singularity in $R=0$ but this is impossible as given two mass particles of radius r_1 and r_2 we would have the maximum following force:

$$F_G=G\frac{m_1m_2}{(r_1+r_2)^2} \tag{12.1.96}$$

✍**Example:**

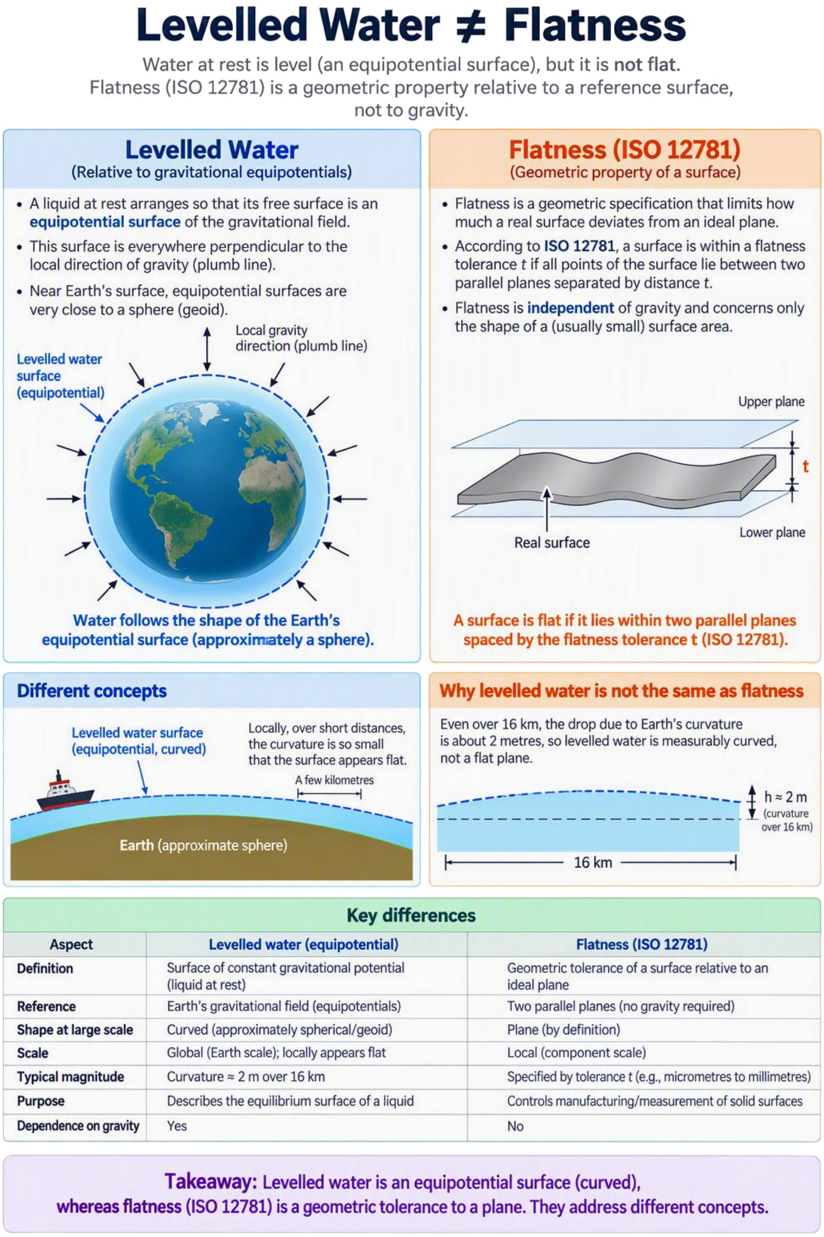
At the Earth's equator the radius is of 6378 [km] and at the poles of 6357 [km]. Therefore we have:

$$a_{\text{eq.}}=\frac{MG}{R_{\text{eq.}}}=9.800\,[\text{m}\cdot\text{s}^{-1}] \qquad a_{\text{po.}}=\frac{MG}{R_{\text{po.}}}=9.865\,[\text{m}\cdot\text{s}^{-1}] \tag{12.1.97}$$

---

[7] In the *Webster's ninth new collegiate dictionary*, "level" is first defined as : « *having no parti higher than another: conforming to the curvature of the liquid parts of the Earth's surface* »

Then the acceleration at the equator is equal to $9.800/9.865 \cong 99.34\%$ to that at the poles.



Levelled Water ≠ Flatness

Water at rest is level (an equipotential surface), but it is **not flat.**
Flatness (ISO 12781) is a geometric property relative to a reference surface, not to gravity.

Levelled Water

(Relative to gravitational equipotentials)

- A liquid at rest arranges so that its free surface is an **equipotential surface** of the gravitational field.
- This surface is everywhere perpendicular to the local direction of gravity (plumb line).
- Near Earth's surface, equipotential surfaces are very close to a sphere (geoid).

Local gravity direction (plumb line)
Levelled water surface (equipotential)

Water follows the shape of the Earth's equipotential surface (approximately a sphere).

Flatness (ISO 12781)

(Geometric property of a surface)

- Flatness is a geometric specification that limits how much a real surface deviates from an ideal plane.
- According to **ISO 12781**, a surface is within a flatness tolerance *t* if all points of the surface lie between two parallel planes separated by distance *t*.
- Flatness is **independent** of gravity and concerns only the shape of a (usually small) surface area.

A surface is flat if it lies within two parallel planes spaced by the flatness tolerance t (ISO 12781).

Different concepts

Levelled water surface (equipotential, curved)
Locally, over short distances, the curvature is so small that the surface appears flat.
A few kilometres
Earth (approximate sphere)

Why levelled water is not the same as flatness

Even over 16 km, the drop due to Earth's curvature is about 2 metres, so levelled water is measurably curved, not a flat plane.

Key differences

Aspect	Levelled water (equipotential)	Flatness (ISO 12781)
Definition	Surface of constant gravitational potential (liquid at rest)	Geometric tolerance of a surface relative to an ideal plane
Reference	Earth's gravitational field (equipotentials)	Two parallel planes (no gravity required)
Shape at large scale	Curved (approximately spherical/geoid)	Plane (by definition)
Scale	Global (Earth scale); locally appears flat	Local (component scale)
Typical magnitude	Curvature ≈ 2 m over 16 km	Specified by tolerance t (e.g., micrometres to millimetres)
Purpose	Describes the equilibrium surface of a liquid	Controls manufacturing/measurement of solid surfaces
Dependence on gravity	Yes	No

Takeaway: Levelled water is an equipotential surface (curved), whereas flatness (ISO 12781) is a geometric tolerance to a plane. They address different concepts.

It is very important to notice that the mutual forces of attraction acting on two spherical masses are always of equal magnitude!

Using Maple™ 17.00, we can simulate the plane trajectory of a satellite relative to n number of fixed mass (thanks to Forhad Ahmed for his script). Here below is given the basic script that you can customize to your tastes and... feel free to give us your personal work if you have brought significant improvement to this script:

```

value...
```

Remark

Equalizing the centrifugal (fictional) force and gravitational force, it is quite easy to get an approximation of the speed of rotation of the planets in their orbits. The reader that will do the calculation will see that the value for the planets of our Solar System is around a speed of about $100,000\,[\mathrm{km}\cdot\mathrm{h}^{-1}]$.

From this last relation, let us come back briefly on our third Kepler's law and detail it a little bit to show that it is valid for any type of conical orbit and to determine the expression of its constant.

Expressed in the Frenet coordinate system (see section Differential Geometry page 2863), and decomposed into its normal (centripetal) and tangential acceleration, the acceleration in respect to a geocentric reference frame (in the case of a referential located at the mass center of the system the expression change a little bit!) is written:

$$a_{tg}=0 \qquad a_n=\frac{v^2}{R} \tag{12.1.98}$$

From previous developments (3rd Kepler's law):

$$T^2=c^{te}R^3 \tag{12.1.99}$$

and:

$$T^2=4\pi^2\frac{R^2}{v^2} \tag{12.1.100}$$

the constant of Kepler's third law takes for value (it is a formulation sometimes used in practice but not a strictly necessary step in this development):

$$c^{te}=4\pi^2\frac{R}{v^2}\frac{1}{R^2}=4\pi^2\frac{1}{a_n}\frac{1}{R^2} \tag{12.1.101}$$

but as we also have:

$$a_n=g=\frac{v^2}{R}=\frac{Gm}{R^2}\Leftrightarrow v^2=\frac{Gm}{R} \tag{12.1.102}$$

then:

$$c^{te}=4\pi^2\frac{R}{\frac{Gm}{R}}\frac{1}{R^2}=4\pi^2\frac{R^2}{Gm}\frac{1}{R^2}=\frac{4\pi^2}{Gm} \tag{12.1.103}$$

Therefore:

$$T^2=\frac{4\pi^2}{Gm}R^3 \tag{12.1.104}$$

Finally, the third Kepler law can be found frequently in the literature as follows:

$$\boxed{\frac{R^3}{T^2}=\frac{Gm}{4\pi r^2}} \tag{12.1.105}$$

But now let us consider again our figure of the center of mass study (see section Classical Mechanics page 3213):

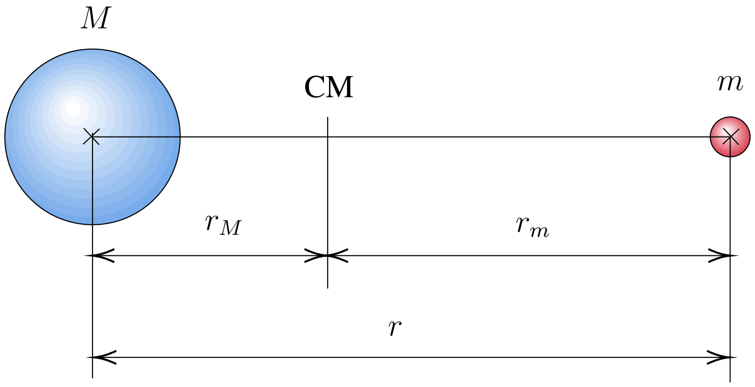

Figure 12.25: **Binary system center of mass (profile view)**

And let us have a look at circular orbits in the center of mass frame!

First we look at the forces acting on body M:

$$F=-\frac{GMm}{r^2}\qquad F_{\text{cent}}=\frac{Mv_M^2}{r_M} \tag{12.1.106}$$

The forces balance, so:

$$\frac{GMm}{r^2}=\frac{Mv_M^2}{r_M} \tag{12.1.107}$$

We know that in the simple case of a circular orbit (circular kinematics):

$$v_M=\frac{2\pi r_M}{T_M} \tag{12.1.108}$$

We insert this into the previous equation and we get after some algebra:

$$\frac{Gm}{r^2}=\frac{4\pi r_M}{T_M^2} \tag{12.1.109}$$

What is r_M? From the definition of center of mass we know that (see section Classical Mechanics page 3213):

$$r_M=\frac{m}{M}r_m=\frac{m}{M}(r-r_M)=\frac{M}{M+m}r \tag{12.1.110}$$

We plug r_M into our equation and now we get:

$$\frac{Gm}{r^2}=\frac{4\pi^2}{T^2}\frac{M}{M+m}r \tag{12.1.111}$$

or after rearranging terms:

$$\boxed{T=2\pi\sqrt{\frac{r^3}{G(M+m)}}} \tag{12.1.112}$$

So we can use this 3rd Kepler's law to determine the total mass a binary pair if we know the period T!!! As the star masses are well estimated using the HR diagram we better understand how astronomers estimate orbiting planet mass knowing the period (in fact they also use the luminosity variation). In fact it is not as simple as there is no reason why we should be looking directly onto the orbital plane of the binary system. In other words, the apparent orbit is almost never the true orbit (which is what we need to do the calculation).

This interlude performed, let us come back on our Newton's gravitation law:

$$F_G=G\frac{mM}{R^2} \tag{12.1.113}$$

From the law of gravitation, we can find back Kepler's law. Besides, we have already done it for the second and third law of Kepler, since it is these that we used to get this latter relation (however it's a little bit the snake eating its tail...).

In vector notation we have therefore:

$$\vec{F}_G=M\frac{Gm}{R^2}\frac{\vec{R}}{\|\vec{R}\|} \tag{12.1.114}$$

Identically to the electric field (see section Electrostatics page 3969), we can develop:

$$\vec{F}_G=M\sum_i\left(\frac{Gm_i}{\|\vec{r}-\vec{r}_i\|^2}\frac{\vec{r}-\vec{r}_i}{\|\vec{r}-\vec{r}_i\|}\right)=m\vec{a} \tag{12.1.115}$$

As the electric field is derived from an electric potential, identically, the gravitational field derived from a gravitational potential. By performing exactly the same development as in our study of electromagnetism for the first Maxwell equation (see section Electrodynamics page 4095), we prove that:

$$\vec{a}=\vec{\nabla}\cdot\varphi \tag{12.1.116}$$

where φ is the "gravitational potential" that varies inversely with the relative distance of the body (this confirms what we had proved in our study of Noether's theorem in the section on Principles) and is therefore equal to:

$$\varphi=\frac{GM}{r}\;[\mathrm{J}\cdot\mathrm{kg}^{-1}] \tag{12.1.117}$$

Remark

We often encounter this potential in the section of General Relativity (see page 5720). It is therefore appropriate to remember it if possible!

Notation which obviously implies the following relation:

$$\vec{F}=-m\vec{\nabla}\cdot\varphi \tag{12.1.118}$$

Remark

Obviously in the absence of field, we have $\varphi=c^{te}$ and therefore $\vec{a}$ will be zero.

As in the section of Electromagnetism, again, we prove as we did for the first Maxwell equation:

$$\Phi_{\vec{a}}=\oint_{\Sigma}\vec{a}\circ\mathrm{d}\vec{S}=\oint_{V}(\vec{\nabla}\circ\vec{a})\mathrm{d}V=4\pi Gm\Leftrightarrow\vec{\nabla}\circ\vec{a}=4\pi G\rho \tag{12.1.119}$$

If we express this equation in terms of a gravitational potential φ (also often denoted by the letter U as in Electrostatic...), we get:

$$\vec{\nabla}\circ(\vec{\nabla}\cdot\varphi)=4\pi G\rho \tag{12.1.120}$$

that we write more aesthetically with the scalar Laplacian operator (see section Vector Calculus page 1899):

$$\boxed{\Delta\cdot\varphi=4\pi G\rho} \tag{12.1.121}$$

which is nothing else than the "Newton-Poisson equation" that we will also meet again in our study of General Relativity (it has an important place for validation reasons of Einstein's Gravitation theory)!

This equation means that the Newtonian gravitational theory can be resume to say that the gravitational field is described by a single potential φ generated by the volume mass density and determining the acceleration of a test particle immersed in the outfield φ.

With Newton's important achievements - building, of course, on the work of the great thinkers who preceded him - civilization reached an extremely high level of knowledge about the universe. Newtonian mechanics and also the optics, astronomy, and mathematics to which Newton contributed were immensely valuable in helping us gain an understanding of the vast and complicated physical world around us. The progress made by Newton and others allowed us to see clearly how planets move and how the force of gravity operates in nature. Newton's theory of gravity is so profound and so all-encompassing that its laws govern everything from the fall of apples to the ground to the orbiting of the Earth by the Moon; from the revolutions of the planets around the Sun (actually a G2V-type star, aka yellow dwarf) to the actions of springs and the trajectories of cannonballs; from the behaviour of billiard balls to the energy of an accelerating car. Newtonian mechanics explains the world to a stunningly accurate degree. In the 120th century (holocene calendar), Einstein would refine Newton's theories to account for instances where the speed of light is approached or very great mass is involved. But for the time, Newton's achievements truly opened a new world for physical science. In the following two centuries, science would consolidate its gains, and the church (and religions in general) would have to retreat from its position as the source of truth about how the world works.

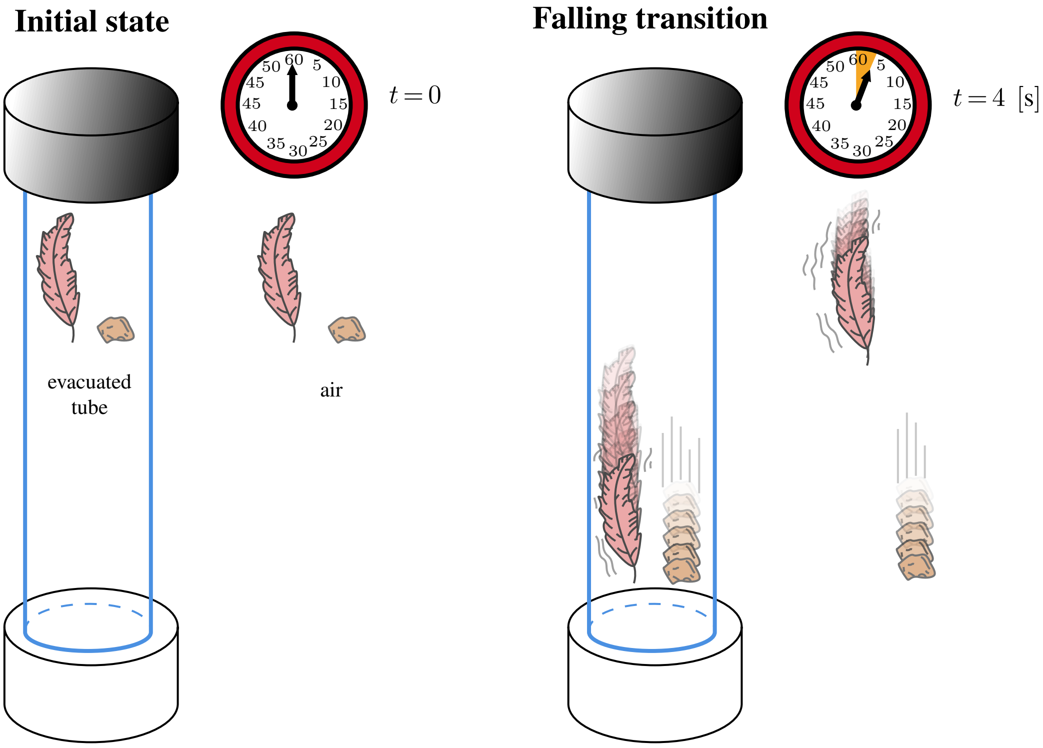

Figure 12.27: **Illustration of the famous experiment done in High Schools that provides evidence falling is primarily due to gravity**

The real-life experiment below shows that the speed of a freely falling object is independent of its mass. When there is air in the tube, the two objects have a different falling speed, because the objects feel the effects of a viscous flow. Since the shape and surface of the object play a key role in a viscous flow, the feather is strongly braked (high drag) while the lead ball has comparatively little drag:

12.1.4.1 Cavendish Experiment

The Newtonian gravitational constant G, which is one of the most important fundamental physical constants in nature, plays a significant role in the fields of theoretical physics, geophysics, astrophysics and astronomy. Although G was the first physical constant to be introduced in the history of science, it is considered to be one of the most difficult to measure accurately so far.

The "Cavendish experiment", performed in 11797–11798 (holocene calendar) by English scientist Henry Cavendish, was the first horizontal (the fact that the experiment is horizontal guarantees that the observation has nothing to do with Buoyancy force as the whole experiment remains in the same horizontal plane) experiment to measure the force of gravity between masses in the laboratory and the first to yield accurate values for the gravitational constant.

This experiment consists in a torsion balance that is set up and the gravitational attraction between a pair of large spheres and a pair of smaller spheres is measured in terms of the torsion of the wire from which the smaller spheres are suspended from:

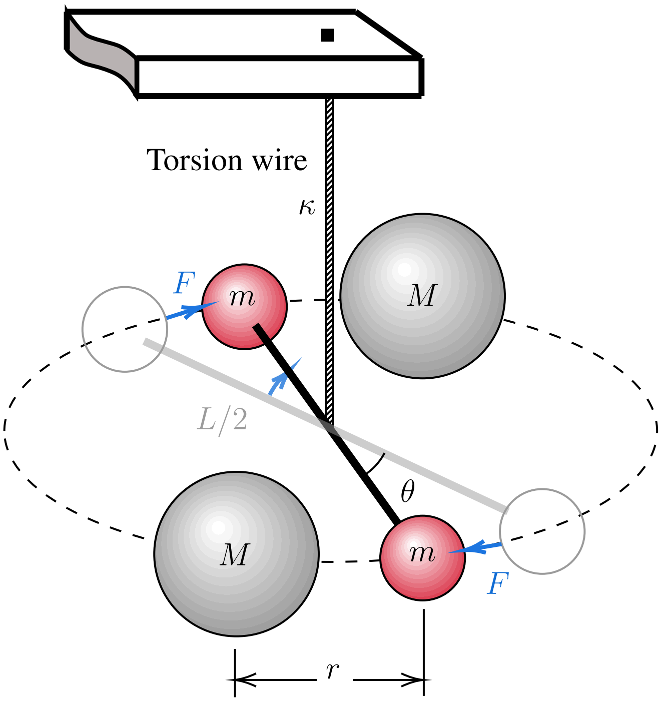

Figure 12.29: **Naive schema of the initial Cavendish experiment**

Drawing of torsion balance apparatus used by Henry Cavendish to measure the gravitational constant in 11798 (holocene calendar). This is a vertical section through the apparatus, including the building that housed it. Copy of Figure 1 from his 11798 (holocene calendar) paper *Experiments to determine the Density of the Earth* published in *Philosophical Transactions of the Royal Society of London*, (part II) 88 p.469-526 (21 June 11798):

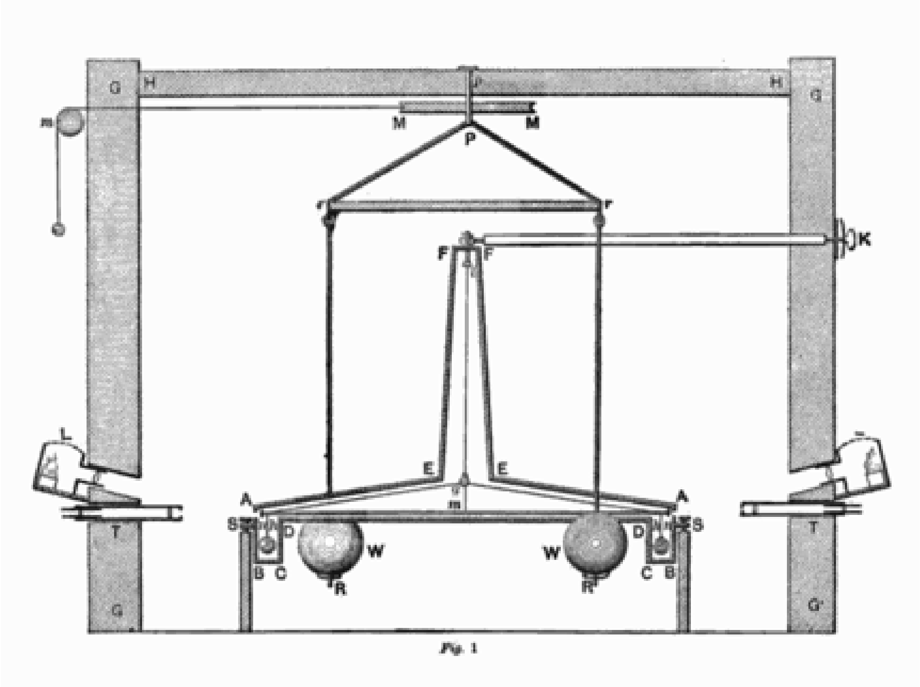

Figure 12.30: **Original schematic Cavendish experiment (author: Henry Cavendish)**

The apparatus consisted of a torsion balance made of a 1.8 [m] wooden rod horizontally suspended from a wire, with two 51 [mm], 0.73 [kg] lead spheres, one attached to each end. Two massive 300 [mm], 158 [kg] lead balls, suspended separately, could be positioned away from or to either side of the smaller balls, 225 [mm] away. The experiment measured the faint gravitational attraction between the small and large balls, which deflected the torsion balance rod by about 0.16" (or only 0.03" with a stiffer suspending wire). Cavendish ensured all the materials used in the experiment were not magnetic. He tried using magnetic material to see the effects. He rotated the apparatus to see if Earth's magnetic field affected the experiment.

The two large balls could be positioned either away from or to either side of the torsion balance rod. Their mutual attraction to the small balls caused the arm to rotate, twisting the suspension wire. The arm rotated until it reached an angle where the twisting force of the wire balanced the combined gravitational force of attraction between the large and small lead spheres. By measuring the angle of the rod and knowing the twisting force (torque) of the wire for a given angle, Cavendish was able to determine the force between the pairs of masses. Since the gravitational force of the Earth on the small ball could be measured directly by weighing it, the ratio of the two forces allowed the relative density of the Earth to be calculated, using Newton's law of gravitation (see derivation further below).

Here below is a contemporary reproduction as close to as possible but not to scale (made in 11977 according to holocene calendar):

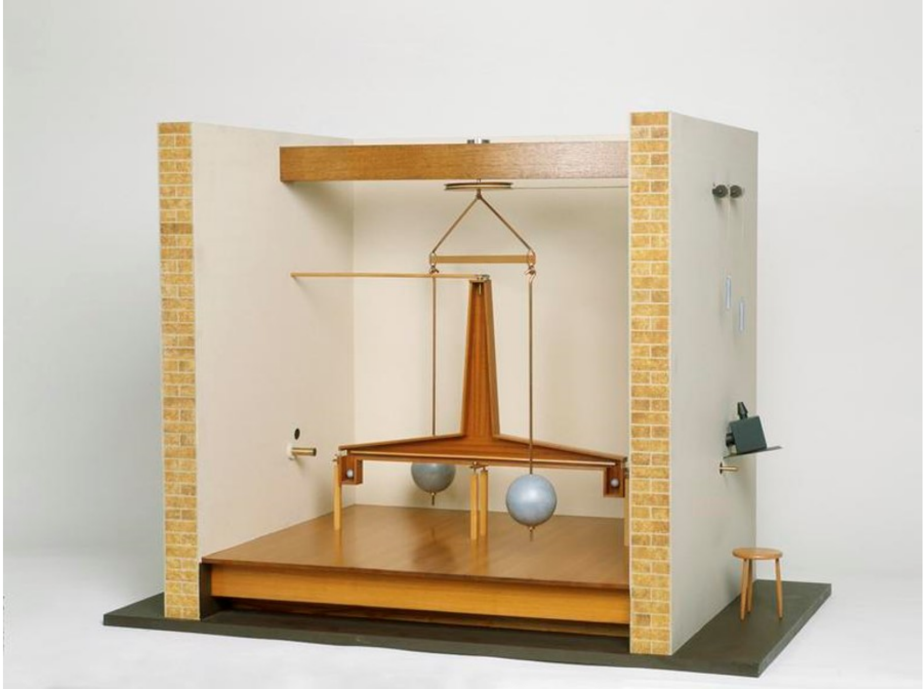

Figure 12.31: Model of Henry Cavendish's torsion balance and gravitational (source: Science Museum Group Collection, licence: CC BY-NC-SA 4.0 Licence)
`https://collection.sciencemuseumgroup.org.uk/objects/co54064/model-of-henry-cavendishs-torsion-balance-gravitational-apparatus-1798`

Cavendish's equipment was remarkably sensitive for its time. The force involved in twisting the torsion balance was very small, $1.74 \cdot 10^{-7}$ [N] (corresponding to a weight of only 0.0177 milligrams!) or about $1/50,000,000$ of the weight of the small balls. To prevent air currents and temperature changes from interfering with the measurements, Cavendish placed the entire apparatus in a mahogany box about 1.98 [m] wide, 1.27 [m] tall, and 14 [cm] thick, all in a closed shed on his estate. Through two holes in the walls of the shed, Cavendish used telescopes to observe the movement of the torsion balance's horizontal rod. The key observable was of course the deflection of the torsion balance rod, which Cavendish measured to be about $0.16''$ (or only $0.03''$ for the stiffer wire used mostly). Cavendish was able to measure this small deflection to an accuracy of better than 0.25 [mm]. The accuracy of Cavendish's result was not exceeded until C. V. Boys' experiment in 11895 (holocene calendar(. In time, Michell's torsion balance became the dominant technique for measuring the gravitational constant G and most contemporary measurements still use variations of it.

The experiment was devised sometime before 11783 (holocene calendar) by geologist John Michell, who constructed a torsion balance apparatus for it. However, Michell died in 11793 (holocene calendar) without completing the work. After his death the apparatus passed to Francis John Hyde Wollaston and then to Cavendish, who rebuilt the apparatus but kept close to Michell's original plan. Cavendish then carried out a series of measurements with the equipment and reported his results in the Philosophical Transactions of the Royal Society in 11798 (holocene calendar).

The following is not the method Cavendish used, but describes how modern physicists would calculate the results from his experiment. From Hooke's law, the torque on the torsion wire is proportional to the deflection angle θ of the balance. The torque is $\kappa\theta$ where κ is the torsion coefficient of the wire. However, a torque in the opposite direction is also generated by the gravitational pull[8] of the masses. It can be written as a product of the attractive force of a large ball on a small ball and the distance $L/2$ to the suspension wire. Since there are two pairs of balls, each experiencing force F at a distance $\frac{L}{2}$ from the axis of the balance, the torque due to gravitational force is $L\cdot F$. At equilibrium (when the balance has been stabilized at an angle θ), the total amount of torque must be zero as these two sources of torque balance out. Thus, we can equate their magnitudes given by the formulas above, which gives the following (see section Mechanics page 3425):

$$\kappa\cdot\theta = L\cdot F \tag{12.1.122}$$

For F, Newton's law of universal gravitation is used to express the attractive force between a large and small ball:

$$F=\frac{GmM}{r^2} \tag{12.1.123}$$

Substituting F into the first equation above gives:

$$\kappa\theta = L\frac{GmM}{r^2} \tag{12.1.124}$$

To find the torsion coefficient κ of the wire, Cavendish measured the natural resonant oscillation period T of the torsion balance:

$$T=2\pi\sqrt{\frac{I}{\kappa}}=2\pi\sqrt{\frac{\text{Inertia}}{\text{Restoring Force}}} \tag{12.1.125}$$

The oscillation is caused by the wire's torsion. It is expected and part of the experiment. The oscillation period is one of the required variables to calculate the value of G!

Assuming the mass of the torsion beam itself is negligible, the moment of inertia of the balance is just due to the small balls. Treating them as point masses, each at $L/2$ from the axis, gives:

$$I=m\left(\frac{L}{2}\right)^2+m\left(\frac{L}{2}\right)^2=2m\left(\frac{L}{2}\right)^2=\frac{mL^2}{2} \tag{12.1.126}$$

and so:

$$T=2\pi\sqrt{\frac{mL^2}{2\kappa}} \tag{12.1.127}$$

Solving this for κ, substituting into:

$$\kappa\theta = L\frac{GmM}{r^2} \tag{12.1.128}$$

and rearranging for G, the result is:

$$\boxed{G=\frac{2\pi^2Lr^2\theta}{MT^2}} \tag{12.1.129}$$

---

[8] Keep in mind that's in the framework of the Newtonian model of gravity as we that in General Relativity there are no "pull".

When the lead sphere is in its equilibrium position, it performs oscillations, in the plane of all the masses, about a particular equilibrium position θ. While in theory, the experiment can be left long enough for the oscillations to effectively decay completely, in reality this isn't possible due to the eventuality of outside forces affecting the experiment.

Remark

Once G has been found, the attraction of an object at the Earth's surface to the Earth itself can be used to calculate the Earth's mass and density. From:

$$mg=\frac{GmM_{\text{earth}}}{R_{\text{Earth}}^2} \tag{12.1.130}$$

That simplifies as:

$$M_{\text{earth}}=\frac{gR_{\text{Earth}}^2}{G} \tag{12.1.131}$$

Therefore:

$$\rho_{\text{Earth}}=\frac{M_{\text{Earth}}}{\frac{4}{3}\pi R_{\text{Earth}}^3}=\frac{3g}{4\pi R_{\text{Earth}}\,G} \tag{12.1.132}$$

Cavendish found that the Earth's density was 5.448 ± 0.033 times that of water (although due to a simple arithmetic error, found in 1821 by Francis Baily, the erroneous value 5.480 ± 0.038 appears in his paper). The current accepted value is 5.514 [g $\cdot$ [cm^3].

G is difficult to measure because gravity is by far the weakest of the four fundamental forces and because it is impossible to shield experiments from the gravitational influences of their environment. Today the official value from the 2014 CODATA is $G=6.67408\cdot 10^{-11}$ [m$^3\cdot$ kg$^{-1}\cdot$ s^{-2}] in units of metres cubed per kilogram per second squared, with a relative uncertainty of 1500 parts per million (ppm) (Cavendish method leads to $G=6.74\cdot 10^{-11}$ [m$^3\cdot$ kg$^{-1}\cdot$ s^{-2}]). By contrast, the mass of the electron is known with an accuracy of 0.08 ppm.

Cavendish style experimental configuration are still used today (among other methods). Below we can see the Big G experiment at BIPM[9] (the torsion cable is in a vacuum tube in the middle):

---

[9] Bureau International des Poids et Mesures

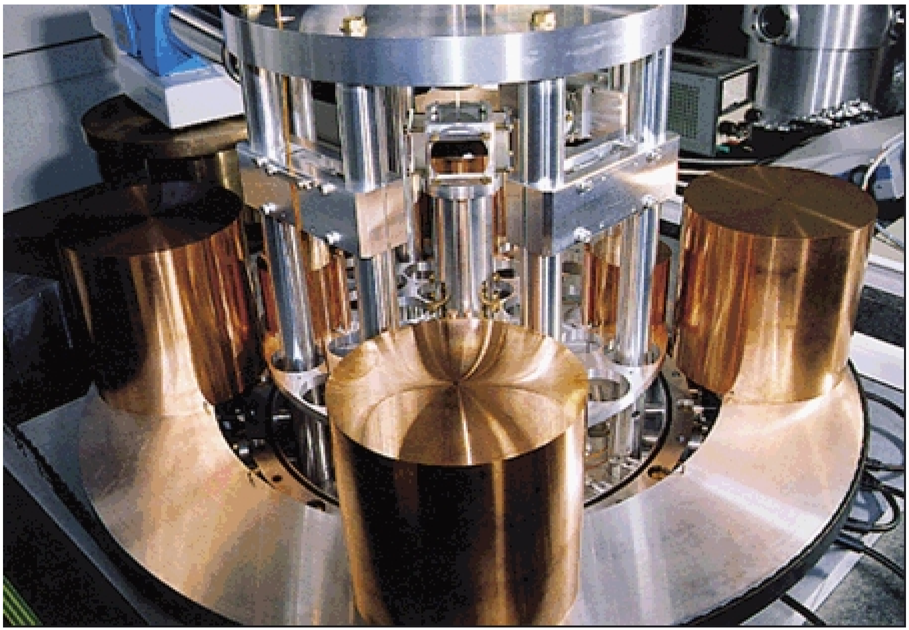

Figure 12.32: **Big G experiment at BIPM**

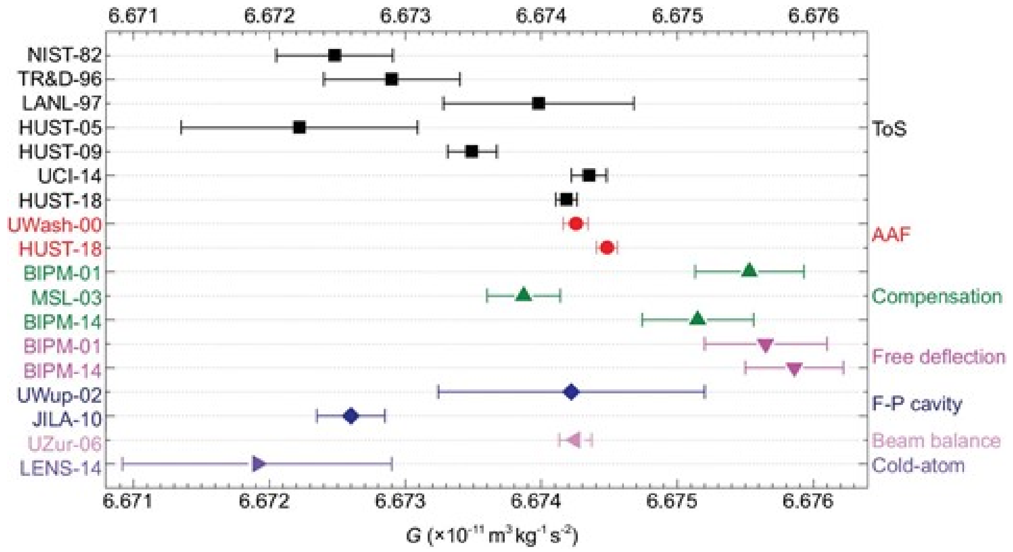
In the BIPM-01 experiment (see in the figure above), a four-mass configuration was used in both the test mass system and the source mass system. The test mass was suspended from a torsion strip in order to give much improved stability with practical independence of the material properties. In the compensation mode, the gravitational torque of the source masses was made equal to an electrostatic torque on the test masses. In the deflection mode, the torsion balance experiences the deflection angle that was related to the gravitational torque. The final results were $(6.67553 \pm 0.00040) \cdot 10^{-11}\,[\,\mathrm{m}^3 \cdot\ \mathrm{kg}^{-1} \cdot\ \mathrm{s}^{-2}]$ with a relative uncertainty of 60 ppm for the compensation mode and $(6.67565 \pm 0.00045)\,[\,\mathrm{m}^3 \cdot\ \mathrm{kg}^{-1} \cdot\ \mathrm{s}^{-2}]$ with a relative uncertainty of 67 ppm for the deflection mode. The combined value was $G = (6.67559\ \pm 0.00027)\,[\,\mathrm{m}^3 \cdot\ \mathrm{kg}^{-1} \cdot\ \mathrm{s}^{-2}]$ with a relative uncertainty, taking account of correlations, of 40 ppm.

In 12014 (holocene calendar), the BIPM group rebuilt and replaced most of the apparatus. Lots of key parameters were improved, including the test and source mass coordinates, calibration of the angle measurements, and precision of the torque measurements and timing measurements. The compensation and deflection modes yielded respective values of G of $(6.67515 \pm 0.00041) \cdot 10^{-11}\,[\,\mathrm{m}^3 \cdot\ \mathrm{kg}^{-1} \cdot\ \mathrm{s}^{-2}]$ and $(6.67586 \pm 0.00036) \cdot 10^{-11}\,[\,\mathrm{m}^3 \cdot\ \mathrm{kg}^{-1} \cdot\ \mathrm{s}^{-2}]$ with relative uncertainties of 61 ppm and 54 ppm, respectively. The weighted mean was $(6.67554 \pm 0.00016)\,[\,\mathrm{m}^3 \cdot\ \mathrm{kg}^{-1} \cdot\ \mathrm{s}^{-2}]$ with a relative uncertainty of 24 ppm , taking account of all correlations. The new value is just 7 ppm below the BIPM-01 result. However, the BIPM-01 and BIPM-14 values are larger than the CODATA 2014 recommended value by 226 ppm and 219 ppm, respectively.

The Cavendish experiment has been successfully repeated countless times. It is a common experiment done in schools & universities. Research-grade experiments give a consistent value of G.

Below we can see the G values adopted in the CODATA 2014 recommended value and two values of HUST-18. The labels on the left denote the identification of each value, and the labels on the right denote the different methods. The same symbol and color represent use of the same method:



Apart from the many Cavendish experiments variations, there are hundreds of experiments that proves General Relativity (and its Newtonian approximation) and therefore our model of gravity as being accurate (i.e. a "scientific theory") like the Gravity Probe B experiment, the CERN Alpha experiment, the Zero Gravity research facility from NASA, the ZARM drop tower (Bremen, Germany), the Kingston Micro-Gravity drop tower, the Beijing drop tower (China), the JAMIC drop tower, etc.

Table 12.4: **Most well known variations of the Cavendish experiment and others**

Below the reader can see a photo of the experimental setup used by a lot of engineering schools and universities around the World to reproduce the Cavendish experiment (Gravitation Torsion balance sold by Leybold Company for betwen 2,000 and 3,000 USD):

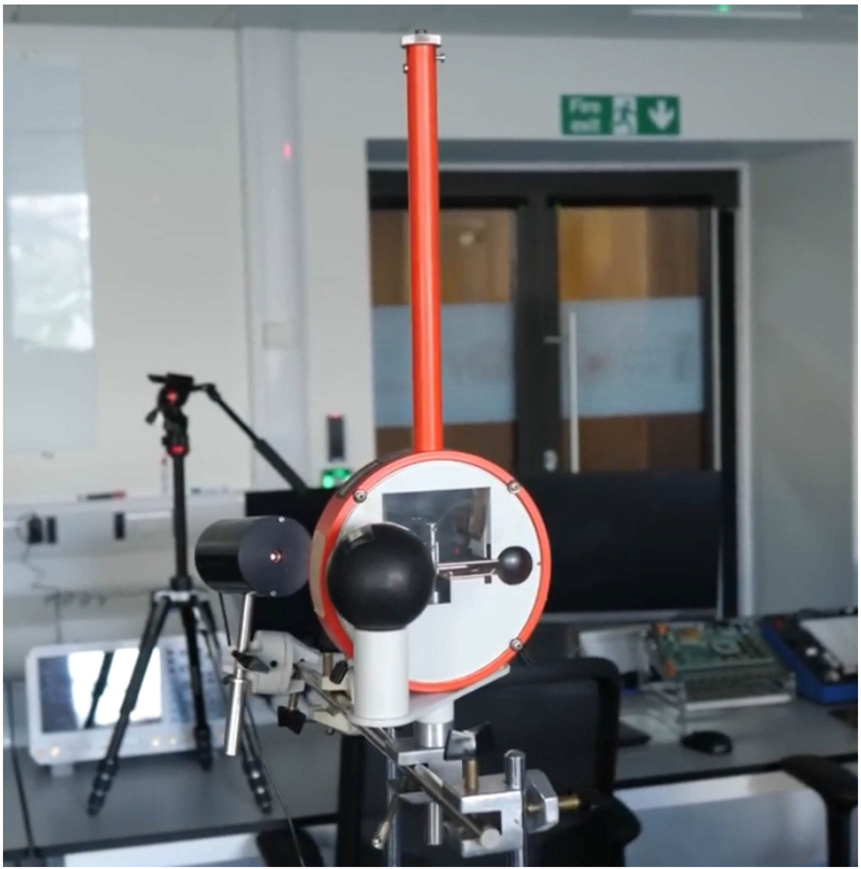

Figure 12.33: **Gravitation Torsion balance by Leybold**

Let's have a little bit fun now with the Newton's gravitation equation to get some interesting and curious results:

12.1.4.2 Gaussian formulation of Newtonian Gravity

As we have just mentioned it and proved in the section of Electrodynamics (see page 4097), an alternative formulation of Newtonian gravity is: Gauss's Law for gravity. It states that the acceleration $\vec{a}$ due to gravity of a mass m (not necessarily a point mass) is given by:

$$\boxed{\Phi_{\vec{a}}=\oint_{\Sigma}\vec{a}\circ\mathrm{d}\vec{S}=\oint_{\Sigma}\vec{a}\circ\vec{n}\mathrm{d}S=-4\pi Gm} \tag{12.1.133}$$

where the $-$ sign we have it's purpose of guarantee a positive scalar acceleration.

For example, let's use Gauss's law to find the acceleration a due to the gravity of a point mass m.

We begin with a point mass m sitting in space. We now need to construct an imaginary closed surface S surrounding m. While in theory any surface would do, we should pick a surface that will make the integral easy to evaluate. Such a surface should have these properties:

P1. The gravitational acceleration $\vec{a}$ should be either perpendicular or parallel to S everywhere.

P2. The gravitational acceleration $\vec{a}$ should have the same value everywhere on S (or it may be zero on some parts of S).

P3. The surface S should pass through the point at which you wish to calculate the acceleration due to gravity.

If we can find a surface S that has these properties, the integral will be very simple to evaluate. For the point mass, we will choose S to be a sphere of radius r centered on mass m. Since we know $\vec{a}$ points radially inward toward mass m, it is clear that g will be perpendicular to S everywhere. Also, by symmetry, it is not hard to see that $\vec{a}$ will have the same value everywhere on S.

Having chosen a surface S, let us now apply Gauss's law for gravity. The law states that for recall that:

$$\oint_{\Sigma} \vec{a} \circ \vec{n} \mathrm{d}S = -4\pi G m \qquad (12.1.134)$$

Now everywhere on the sphere $\mathcal{S}^2$, we have $\vec{a} \circ \vec{n} = -g$ (since $\vec{a}$ and n are anti-parallel g points inward, and n points outward). Since g is a constant for a perfect sphere, the previous relation becomes:

$$-g \oint_{\Sigma} \mathrm{d}S = -4\pi G m \qquad (12.1.135)$$

Now the integral is very simple: it is just $\mathrm{d}S$ integrated over the surface of a sphere, so it's just the area of a sphere (see section Geometric Shapes page 2964):

$$-g \oint_{\Sigma} \mathrm{d}S = -g 4\pi r^2 = -4\pi G m \qquad (12.1.136)$$

or (cancelling -4π on both sides):

$$g = \frac{Gm}{r^2} \qquad (12.1.137)$$

and it's in agreement with the Gravitational Newton law! This result suggests that the gravity of a solid spherical ball to an exterior object can be simplified as that of a point mass in the center of the ball with the same mass!!!

Hence, the reader must keep in mind that the inverse square law applies to point sources. In Classical Mechanics there are not point sources (so quantum stuff is not the subject here!), so strictly speaking it never applies. In nature we have extended sources. If we are far away from the source, then it looks like a point source, so the inverse square law is a good approximation. Close to the source, the inverse square law doesn't apply unless the source happens to be perfectly spherical. Even in that case the law breaks down once we cross the surface and are inside the source.

Our planet isn't however a perfect sphere, it isn't also egg shaped, but it's a geoid (oblate sphere) and it's gravity field is even more complex that it's inside is not homogeneous.

Figure 12.34: **Illustrated difference between a sphere, ellipsoid en geoid**

This gravity map from the GRACE (Gravity Recovery and Climate Experiment) satellite shows the variation of the gravitational field across Earth's surface; red indicates higher gravitational field strength and blue lower:

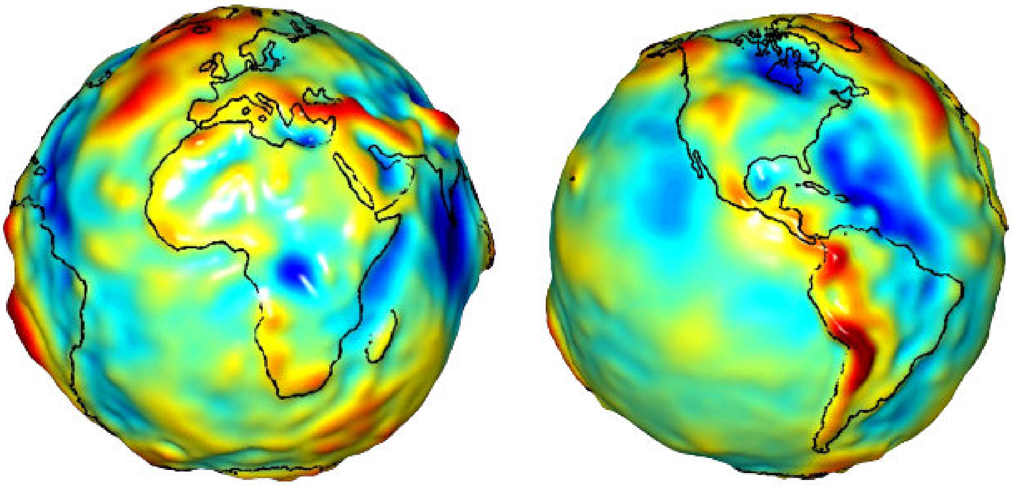

Figure 12.35: **Gravitational field across Earth's surface**

The place with the lowest gravitational field strength is Mexico City (0.28% below average) helped by it's elevation, more than two thousand metres above sea level. The highest gravitational field strength is found in Helsinki (0.13% above average).

So the flat earthers and some believers (following some holy books that we will not mention here) have to explain why everywhere in the world they can measure a falling object which acceleration corresponds to an approximately spherical Earth if that latter is flat...

As flat earthers sometimes challenge physicists to prove that the Newton law is not the same for a flat Earth (I was also challenged once... and this was a very bad idea from my opponent) here is the proof!

Figure 12.36: **Schematic idea of a flat planet like... Earth......**

In this case, the appropriate Gaussian surface S is a "pillbox" shape - a short cylinder whose flat faces - (of area A) are parallel to the plane of mass. In this case, everywhere along the curved surface of S, the gravitational acceleration $\vec{a}$ is perpendicular to the outward normal unit vector $\vec{n}$, so the curved sides of S contribute nothing to the integral. Only the flat ends of the pillbox-shaped surface S contribute to the integral. On each end, $\vec{a}$ is anti-parallel to $\vec{n}$, so $\vec{a}\circ\vec{n}=-g$ on the ends.

Now apply Gauss's law to this situation:

$$\oint_{\Sigma}\vec{a}\circ\vec{n}\mathrm{d}S=-4\pi Gm \tag{12.1.138}$$

Here the integral needs only to be evaluated over the two flat ends of S. Since $\vec{a}\circ\vec{n}=-g$, we can bring $-g$ outside the integral to get:

$$-g\oint_{\Sigma}\mathrm{d}S=-4\pi Gm \tag{12.1.139}$$

The integral in this case is just the area of the two ends of the cylinder, $2A$ (one circle of area A from each end). This gives:

$$-g(2A)=-4\pi Gm \tag{12.1.140}$$

Now let us look at the right-hand side of this equation. The mass m is the total amount of mass enclosed by surface S. Surface S is sort of a "cookie cutter" that punches a circle of area A out of the plane. The mass enclosed by S is a circle of area A and surfacic density σ, so it has mass σA. Then the previous relation becomes:

$$g=2\pi G\sigma \tag{12.1.141}$$

Note that this is a constant: the acceleration due to gravity of an infinite plane of mass m is independent of the distance from the plane...! We will detail the much more complex case of a finite homogeneous disc further below at page 5284.

So Flat-Earther have difficulties to only difficulties to explain this but also are not able to find the corresponding value of g in their laboratory or home garage...

12.1.4.3 Shell Theorem

The shell theorem gives gravitational simplifications that can be applied to objects inside or outside a spherically symmetrical body. This theorem has particular application to astronomy.

Isaac Newton proved the shell theorem and stated that:

1. A spherically symmetric body affects external objects gravitationally as though all of its mass were concentrated at a point at its center.
2. If the body is a spherically symmetric shell (i.e., a hollow ball), no net gravitational force is exerted by the shell on any object inside, regardless of the object's location within the shell.

A corollary is that, and we will prove it, that inside a solid sphere of constant density, the gravitational force varies linearly with distance from the center, becoming zero by symmetry at the center of mass.

Given an object located outside of the Earth and r is the distance of the object to the center of the Earth, we have:

$$mg(r)=G\frac{Mm}{r^2} \tag{12.1.142}$$

it comes:

$$g(r)=G\frac{M}{r^2} \tag{12.1.143}$$

If the object is placed at the surface of the Earth or radius R, we have ($r=R$):

$$g_0=G\frac{M}{R^2} \tag{12.1.144}$$

From the two previous relations it comes therefore:

$$\boxed{g(r)=g_0\left(\frac{R}{r}\right)^2} \tag{12.1.145}$$

At the surface we have then well (we expected this result...):

$$g_0=G\frac{M}{R^2} \tag{12.1.146}$$

Now, if the object is located inside the Earth by denoting the distance from the center by the letter r and the central mass by M', we have:

$$mg(r)=G\frac{M'm}{r^2} \tag{12.1.147}$$

Let us introduce the density ρ that we will assume equal everywhere:

$$M=\frac{4}{3}\pi R^3\rho \tag{12.1.148}$$

$$M'=\frac{4}{3}\pi r^3\rho \tag{12.1.149}$$

By combining these last four relations, we get:

$$\boxed{g(r)=g_0\frac{r}{R}} \tag{12.1.150}$$

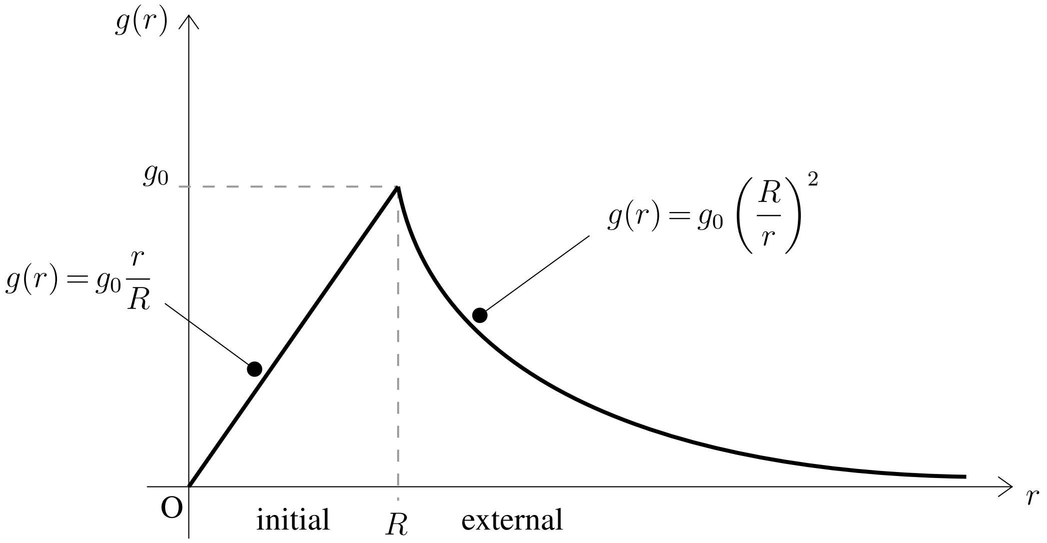

Figure 12.37: **Internal/External gravitational acceleration profile of a mass body**

For many people this result is quite counter-intuitive (do a little survey around you, you'll see).

Remark

In addition to gravity, the shell theorem can also be used to describe the electric field generated by a static spherically symmetric charge density, or similarly for any other phenomenon that follows an inverse square law. The derivations below focus on gravity, but the results can easily be generalized to the electrostatic force.

12.1.4.4 Orbital speed

We will prove now an obvious property of orbits that will be useful to us later to study of what seem to be an anomaly with structure of the size of galaxies.

The orbital speed of a body, generally a planet, a natural satellite, an artificial satellite, or a multiple star, is the speed at which it orbits around the barycenter of a system, usually around a more massive body. It can be used to refer to either the mean orbital speed, i.e. the average speed as it completes an orbit, or the speed at a particular point in its orbit such as perihelion.

We have proved just earlier above the origin of Newton's law. For planets thus considered as physical points in stable circular orbit, there must be balance between (fictional) centrifugal and gravitational force. So we have:

$$m\frac{v^2}{R}=\frac{GmM}{R^2} \tag{12.1.151}$$

where we easily deduce:

$$v=\sqrt{\frac{GM}{R}} \tag{12.1.152}$$

Which is approximately in good agreement with the experimental measurements as shown in the figure below:

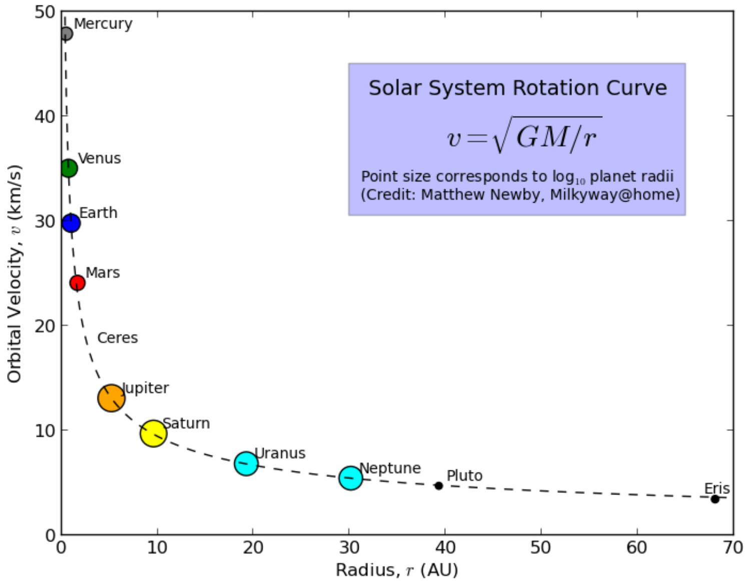

Figure 12.38: **Orbital speed characteristic curve**

But as we will prove it in the section of Aerospace Engineering (Vis-Viva equation at page 8619) in a more general case that orbital speed is given by:

$$\boxed{v=\sqrt{GM\left(\frac{2}{r}-\frac{1}{a}\right)}} \tag{12.1.153}$$

✍**Example:**

Let us consider the case of Earth and Sun (actually a G2V-type star, aka yellow dwarf) system, we have therefore:

$$v_{♁}=\sqrt{GM_{\odot}\left(\frac{2}{r}-\frac{1}{a_{♁}}\right)}=\sqrt{6.674\cdot 10^{-11}\cdot 1.9885\cdot 10^{30}\left(\frac{2}{r}-\frac{1}{150\cdot 10^{30}}\right)}$$
$$=29744.746\cong 29.74\,[\mathrm{km}\cdot\mathrm{s}^{-1}] \tag{12.1.154}$$

Let us consider now two cases:

- The aphelion $r:=a_{♁}$, then we have:

$$v_{♁,\text{aph.}}=\sqrt{\frac{GM_{\odot}}{a_{♁}}}=29744.746\cong 29.74\,[\mathrm{km}\cdot\mathrm{s}^{-1}] \tag{12.1.155}$$

- The perihelion $r := p_{♁} =$, then we have:

$$v_{♁,\text{perh.}} = \sqrt{GM_{\odot}\left(\frac{2}{p_{♁}} - \frac{1}{a_{♁}}\right)} = 29824.842 \cong 29.82\ [\text{km} \cdot \text{s}^{-1}] \tag{12.1.156}$$

In its elliptical orbit Earth orbital speed increases and decreases periodically. So the tangential acceleration changes all the time. In perihelion the speed as calculated above is about $29.82\ [\text{km} \cdot \text{s}^{-1}]$ and in aphelion about $29.74\ [\text{km} \cdot \text{s}^{-1}]$. To find the order of magnitude of the tang. acc. we can take simply $a = \mathrm{d}v/\mathrm{d}t$ knowing that between the aphelion and perihelion we have a duration of half a year, i.e. $15,779,000$ [s], hence:

$$\bar{a}_{\text{tg}} \cong \frac{\Delta v}{\Delta t} = \frac{v_{♁,\text{perh.}} - v_{♁,\text{aph.}}}{\Delta t_{1/2\ \text{year}}} = \frac{29.82 - 29.74}{15,779,000} \cong 5 \cdot 10^{-6}\ [\text{m} \cdot \text{s}^{-2}] \tag{12.1.157}$$

Hence the fact that we can't we with our Human sense Earth's movement on orbit!

12.1.4.5 Gravitational field of a homogeneous disc

Despite well-established results about the shape of the Earth, which is a geoid the naïve conception of the flat Earth in some cases survives in adults' minds, especially by those indoctrinated by the holy books of all the abrahamic religions that explicitly claim the Earth is flat (and obviously the abrahamic deity could not be wrong... so if you have the faith you have to reject the scientific evidence). So we will prove here that such a shape for the Earth would have huge consequences on the gravitational field of the latter.

However it is not the only reason why we will derive that field! The main reason is that is also useful to understand how is shaped the gravitational field of disc shaped galaxies that can in first approximation be considered as homogeneous disc of matter and makes then more clear why the speed of stars orbiting the center of galaxies are faster when go away from the center rather than slower (as it is case if all the mass is located at the center of the galaxy). Also the result applies identically for the electric field of a homogeneous charged disc (that may be useful too)!

To describe a flat Earth (or a flat disc shaped galaxy), we use a simple model of a thin disc with a uniformly distributed mass. This approach allows for rather simple calculations to demonstrate what would the gravitational field of such a system be!

Remark

All the derivations, figures that follow are mostly a copy/paste with a slight adaptation of the paper [325].

A point mass M located at the origin generates at a point given by the radius-vector $\vec{r}$ a gravitational field with the potential:

$$\varphi(\vec{r}) = -G\frac{M}{\|\vec{r}\|}\ [\text{J} \cdot \text{kg}^{-1}] \tag{12.1.158}$$

where G is the gravitational constant. The respective gravitational field strength Γ is:

$$\Gamma(\vec{r}) = -\operatorname{grad}(\varphi(\vec{r})) = -G\frac{M}{\|\vec{r}\|^2}\frac{\vec{r}}{\|\vec{r}\|} \tag{12.1.159}$$

and hence the attraction force between the mass M and a mass m located at $\vec{r}$ reads:

$$\vec{F} = \Gamma m = -G\frac{Mm}{\|\vec{r}\|^2}\frac{\vec{r}}{\|\vec{r}\|} \tag{12.1.160}$$

which is the well-known Newton's law of gravitation. Note that the vector r points from the mass M to the mass m while the force pulls the mass m towards M, hence the minus sign.

For a set of point masses M_i located at points $\vec{r}_i$ the gravitational potential is:

$$\varphi(\vec{r}) = \sum_i \varphi_i = \sum_i \left(-G\frac{M_i}{\|\vec{r}-\vec{r}_i\|}\right) \tag{12.1.161}$$

yielding in the continuous limit:

$$\varphi(\vec{r}) = -G\int_V \frac{\rho\left(\vec{r}\,'\right)\mathrm{d}V}{\|\vec{r}-\vec{r}\,'\|} \tag{12.1.162}$$

where $\rho\left(\vec{r}\,'\right)$ is the density, or for surface distributions:

$$\varphi(\vec{r}) = -G\int_S \frac{\sigma\left(\vec{r}\,'\right)\mathrm{d}S}{\|\vec{r}-\vec{r}\,'\|} \tag{12.1.163}$$

where $\sigma\left(\vec{r}\,'\right)$ is the surface density.

We will model a flat Earth by a disc of radius R with a constant surface density $\sigma = c^{te}$. It is most convenient to consider this problem in the cylindrical coordinates (r,ϕ,z). Let the observer sit at a point $(r,0,z)$ (the angle doesn't matter given the symmetry of the problem... so take 0 for angle will very likely simplify calculations a bit), and the elementary area $\mathrm{d}S = r'\mathrm{d}r'\mathrm{d}\phi$ has the cylindrical coordinates $(r',\phi,0)$ as visible below:

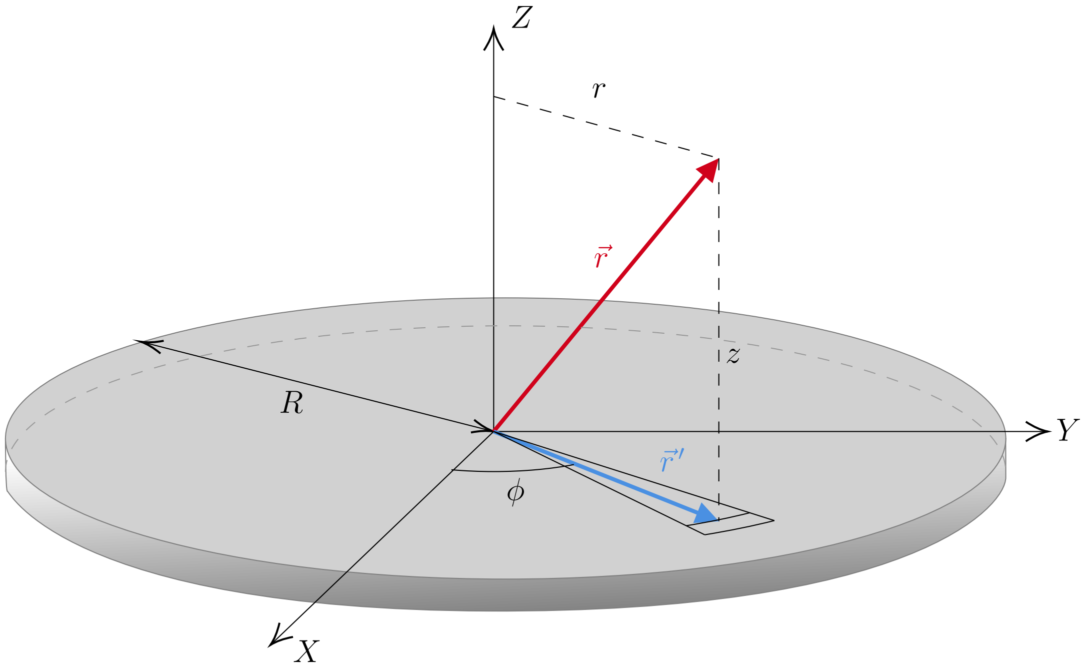

Figure 12.39: **Frame of reference and coordinates of the problem**

To calculate the distance $\|\vec{r}-\vec{r}\,'\|$, one can go back to the Cartesian coordinates, $\vec{r}=(x,y,z)=(r,0,z)$ and $\vec{r}\,'=(r'\cos(\phi),r'\sin(\phi),0)$, so that:

$$\begin{aligned}\|\vec{r}-\vec{r}\,'\| &= \sqrt{(r-r'\cos(\phi))^2+(0-r'\sin(\phi))^2+(z-0)^2}\\ &= \sqrt{r^2-2r'r\cos(\phi)+r'^2+z^2}\end{aligned} \tag{12.1.164}$$

Thus, the gravitational potential is:

$$\varphi(r,z)=-G\sigma\int\limits_0^{2\pi}\mathrm{d}\phi\int\limits_0^{R}\frac{r'\mathrm{d}r'}{\sqrt{r^2+z^2+r'^2-2r'r\cos(\phi)}}\;[\mathrm{J}\cdot\mathrm{kg}^{-1}] \tag{12.1.165}$$

The integration of the above expression appears to be unexpectedly complicated. As far as we know, the result cannot be expressed in elementary functions.

So first let us rewrite the integral as following:

$$\int\frac{x}{\sqrt{x^2-2r\cos(\phi)x+z^2+r^2}}\mathrm{d}x \tag{12.1.166}$$

Let us write x as $\frac{1}{2}(2x-2r\cos(\phi))+r\cos(\phi)$ and split:

$$\int\left(\frac{2x-2r\cos(\phi)}{2\sqrt{x^2-2r\cos(\phi)x+z^2+r^2}}+\frac{r\cos(\phi)}{\sqrt{x^2-2r\cos(\phi)x+z^2+r^2}}\right)\mathrm{d}x \tag{12.1.167}$$

Applying linearity:

$$\int\frac{x-r\cos(\phi)}{\sqrt{x^2-2r\cos(\phi)x+z^2+r^2}}\mathrm{d}x+r\cos(\phi)\int\frac{1}{\sqrt{x^2-2r\cos(\phi)x+z^2+r^2}}\mathrm{d}x \tag{12.1.168}$$

Now we solve first:

$$\int\frac{x-r\cos(\phi)}{\sqrt{x^2-2r\cos(\phi)x+z^2+r^2}}\mathrm{d}x \tag{12.1.169}$$

Substitute:

$$u=x^2-2r\cos(\phi)x+z^2+r^2\longrightarrow\frac{\mathrm{d}u}{\mathrm{d}x}=2x-2r\cos(\phi) \tag{12.1.170}$$

Therefore:

$$\mathrm{d}x=\frac{1}{2x-2r\cos(\phi)}\mathrm{d}u \tag{12.1.171}$$

So we have the primitive:

$$\frac{1}{2}\int\frac{1}{\sqrt{u}}\mathrm{d}u=\sqrt{u}=\sqrt{x^2-2r\cos(\phi)x+z^2+r^2} \tag{12.1.172}$$

Now we focus on:

$$\int\frac{1}{\sqrt{x^2-2r\cos(\phi)x+z^2+r^2}}\mathrm{d}x \tag{12.1.173}$$

First we complete the square:

$$\int \frac{1}{\sqrt{(x-r\cos(\phi))^2-r^2\cos^2(\phi)+z^2+r^2}}\mathrm{d}x \tag{12.1.174}$$

Let us do the following substitution:

$$u=\frac{x-r\cos(\phi)}{\sqrt{-r^2\cos^2(\phi)+z^2+r^2}} \longrightarrow \frac{\mathrm{d}u}{\mathrm{d}x}=\frac{1}{\sqrt{-r^2\cos^2(\phi)+z^2+r^2}} \tag{12.1.175}$$

Hence:

$$\mathrm{d}x=\sqrt{-r^2\cos^2(\phi)+z^2+r^2}\mathrm{d}u \tag{12.1.176}$$

Substituting in the integral leads to:

$$\int \frac{\sqrt{-r^2\cos^2(\phi)+z^2+r^2}}{\sqrt{\left(-r^2\cos^2(\phi)+z^2+r^2\right)u^2-r^2\cos^2(\phi)+z^2+r^2}}\mathrm{d}u=\int\frac{1}{\sqrt{u^2+1}}\mathrm{d}u \tag{12.1.177}$$

This is an usual primitive that we already know:

$$\int \frac{1}{\sqrt{u^2+1}}\mathrm{d}u=\ln\left(\sqrt{u^2+1}+u\right) \tag{12.1.178}$$

Now we undo the substitution with:

$$u=\frac{x-r\cos(\phi)}{\sqrt{-r^2\cos^2(\phi)+z^2+r^2}} \tag{12.1.179}$$

Therefore:

$$\int \frac{1}{\sqrt{x^2-2r\cos(\phi)x+z^2+r^2}}\mathrm{d}x=\ln\left(\sqrt{\frac{(x-r\cos(\phi))^2}{-r^2\cos^2(\phi)+z^2+r^2}+1}+\frac{x-r\cos(\phi)}{\sqrt{-r^2\cos^2(\phi)+z^2+r^2}}\right) \tag{12.1.180}$$

So finally:

$$\begin{aligned}&\int \frac{x}{\sqrt{x^2-2r\cos(\phi)x+z^2+r^2}}\mathrm{d}x\\ &=\int\frac{x-r\cos(\phi)}{\sqrt{x^2-2r\cos(\phi)x+z^2+r^2}}\mathrm{d}x+r\cos(\phi)\int\frac{1}{\sqrt{x^2-2r\cos(\phi)x+z^2+r^2}}\mathrm{d}x\\ &=r\cos(\phi)\ln\left(\sqrt{\frac{(x-r\cos(\phi))^2}{-r^2\cos^2(\phi)+z^2+r^2}+1}+\frac{x-r\cos(\phi)}{\sqrt{-r^2\cos^2(\phi)+z^2+r^2}}\right)\\ &+\sqrt{x^2-2r\cos(\phi)x+z^2+r^2}+c^{te}\end{aligned} \tag{12.1.181}$$

If we simplify:

$$\begin{aligned}
&\int \frac{x}{\sqrt{x^2-2r\cos(\phi)x+z^2+r^2}}\mathrm{d}x\\
&=r\cos(\phi)\ln\left(\left|\frac{\sqrt{x^2-2r\cos(\phi)x+z^2+r^2}+x-r\cos(\phi)}{\sqrt{-r^2\cos^2(\phi)+z^2+r^2}}\right|\right)\\
&+\sqrt{x^2-2r\cos(\phi)x+z^2+r^2}+c^{te}\\
&=r\cos(\phi)\left[\ln\left(\sqrt{x^2-2r\cos(\phi)x+z^2+r^2}+x-r\cos(\phi)\right)-\ln\left(\sqrt{-r^2\cos^2(\phi)+z^2+r^2}\right)\right]\\
&+\sqrt{x^2-2r\cos(\phi)x+z^2+r^2}+c^{te}\\
&=r\cos(\phi)\left[\ln\left(\sqrt{x^2-2r\cos(\phi)x+z^2+r^2}+x-r\cos(\phi)\right)-\frac{1}{2}\ln\left(-r^2\cos^2(\phi)+z^2+r^2\right)\right]\\
&+\sqrt{x^2-2r\cos(\phi)x+z^2+r^2}+c^{te}
\end{aligned} \tag{12.1.182}$$

Now remember that we want the integral with x (i.e. r') between 0 and R. Therefore:

$$\begin{aligned}
&\int\limits_0^R \frac{x}{\sqrt{x^2-2r\cos(\phi)x+z^2+r^2}}\mathrm{d}x\\
&=r\cos(\phi)\left[\ln\left(\sqrt{R^2-2rR\cos(\phi)+z^2+r^2}+R-r\cos(\phi)\right)-\frac{1}{2}\ln\left(-r^2\cos^2(\phi)+z^2+r^2\right)\right]\\
&+\sqrt{R^2-2rR\cos(\phi)+z^2+r^2}\\
&-r\cos(\phi)\left[\ln\left(\sqrt{z^2+r^2}-r\cos(\phi)\right)-\frac{1}{2}\ln\left(-r^2\cos^2(\phi)+z^2+r^2\right)\right]\\
&-\sqrt{z^2+r^2}\\
&=r\cos(\phi)\left[\ln\left(\sqrt{R^2-2rR\cos(\phi)+z^2+r^2}+R-r\cos(\phi)\right)\right]+\sqrt{R^2-2rR\cos(\phi)+z^2+r^2}\\
&-r\cos(\phi)\left[\ln\left(\sqrt{z^2+r^2}-r\cos(\phi)\right)\right]-\sqrt{z^2+r^2}\\
&=\sqrt{R^2-2rR\cos(\phi)+z^2+r^2}-\sqrt{z^2+r^2}\\
&+r\cos(\phi)\left[\ln\left(\sqrt{R^2-2rR\cos(\phi)+z^2+r^2}+R-r\cos(\phi)\right)-\ln\left(\sqrt{z^2+r^2}-r\cos(\phi)\right)\right]
\end{aligned} \tag{12.1.183}$$

The outer integration of this expression, over ϕ, is not possible in elementary function as far as we know (excepted for the term $\sqrt{z^2+r^2}$ obviously!). We will instead expand it into Maclaurin series over r.

So let us denote:

$$\begin{aligned}
f(r,\phi,z)=&\sqrt{R^2-2rR\cos(\phi)+z^2+r^2}-\sqrt{z^2+r^2}\\
&+r\cos(\phi)\left[\ln\left(\sqrt{R^2-2rR\cos(\phi)+z^2+r^2}+R-r\cos(\phi)\right)-\ln\left(\sqrt{z^2+r^2}-r\cos(\phi)\right)\right]
\end{aligned} \tag{12.1.184}$$

And do the Maclaurin expansion at the sixth order:

$$
\begin{aligned}
f(r,z;\alpha) \cong\, & \sqrt{z^2+R^2}-z \\
& +\left[-\frac{R\cos(\phi)}{\sqrt{z^2+R^2}}+\cos(\phi)\left(\ln\left(R+\sqrt{z^2+R^2}\right)-\ln(z)\right)\right]r \\
& +\left[\sqrt{z^2+R^2}\left(\frac{1}{2}\frac{1}{z^2+R^2}-\frac{1}{2}\frac{R^2\cos(\phi)^2}{\left(z^2+R^2\right)^2}\right)+\cos(\phi)\left(\frac{-\cos(\phi)-\frac{R\cos(\phi)}{\sqrt{z^2+R^2}}}{R+\sqrt{z^2+R^2}}+\frac{\cos(\phi)}{\sqrt{z^2}}\right)-\frac{1}{2}\frac{1}{z}\right]r^2 \\
& +\left[\sqrt{z^2+R^2}\left(\frac{1}{2}\frac{R\cos(\phi)}{\left(z^2+R^2\right)}-\frac{1}{2}\frac{R^3\cos(\phi)^3}{\left(z^2+R^2\right)^3}\right)\right. \\
& \left.+\cos(\phi)\left(-\frac{1}{2}\frac{1}{z^2}+\frac{1}{2}\frac{\cos(\phi)^2}{z^2}+\frac{\sqrt{z^2+R^2}\left(\frac{1}{2}\frac{1}{z^2+R^2}-\frac{1}{2}\frac{R^2\cos(\phi)^2}{\left(z^2+R^2\right)^2}\right)}{R+\sqrt{z^2+R^2}}+\frac{1}{2}\frac{-\cos^2(\phi)-\frac{R\cos^2(\phi)}{\sqrt{z^2+R^2}}}{\sqrt{z^2+R^2}\left(R+\sqrt{z^2+R^2}\right)}\right)\right]r^3 \\
& +\left[\sqrt{z^2+R^2}\left(-\frac{1}{8}\frac{1}{\left(z^2+R^2\right)^2}+\frac{3}{4}\frac{R^2\cos(\phi)^2}{\left(z^2+R^2\right)^3}-\frac{5R^4\cos(\phi)^4}{\left(z^2+R^2\right)^4}\right)+\frac{1}{8}\frac{1}{z^2}\right. \\
& +\frac{\cos(\phi)}{\left(z^2+R^2\right)^3\left(R+\sqrt{z^2+R^2}\right)^2}\left(-\frac{1}{6}\frac{\cos(\phi)}{z^2}+\frac{1}{3}\frac{\left(-1+\cos(\phi)^2\right)\cos(\phi)}{z^3}+\frac{\sqrt{z^2+R^2}\left(\frac{1}{2}\frac{R\cos(\phi)}{\left(z^2+R^2\right)^2}-\frac{1}{2}\frac{R^3\cos(\phi)^3}{\left(z^2+R^2\right)}\right)}{R+\sqrt{z^2+R^2}}\right. \\
& +\frac{1}{3}\frac{\cos(\phi)\left(\frac{1}{2}\frac{1}{z^2+R^2}-\frac{1}{2}\frac{R^2\cos(\phi)^2}{\left(z^2+R^2\right)^2}\right)}{R+\sqrt{z^2+R^2}}+\frac{1}{3}\left(-\left(z^2+R^2\right)^{3/2}z^2-\left(z^2+R^2\right)^{3/2}R^2+\left(z^2+R^2\right)^{3/2}R^2\cos(\phi)^2\right. \\
& +2\cos(\phi)^2z^2R^3+\cos(\phi)^2R^5+\cos(\phi)^2\sqrt{z^2+R^2}z^4 \\
& \left.\left.\left.+2\cos(\phi)^2\sqrt{z^2+R^2}z^2R^2+\cos(\phi)^2\sqrt{z^2+R^2}R^4\right)\left(-\cos(\phi)-\frac{R\cos(\phi)}{\sqrt{z^2+R^2}}\right)\right)\right]r^4 \\
& +\ldots
\end{aligned}
\tag{12.1.185}
$$

The reader can get more terms or check the above result with Maple™ 4.00b with the following command:

```
>taylor(sqrt(z^2+r^2+R^2-2*R*r*cos(phi))-sqrt(z^2+r^2)+r*cos(phi)
*(ln(R-r*cos(phi)+sqrt(z^2+r^2+R^2-2*R*r*cos(phi)))-ln(sqrt(r^2+z^2)
-r*cos(phi))),r=0,5);
```

The integration of the first row above is obvious, for the others it's too boring to do that manually. The fastest solution is to use again Maple™ 4.00b integration function!

Therefore we use first:

```
>readlib(coeftayl):
>approx:=taylor(sqrt(z^2+r^2+R^2-2*R*r*cos(phi))-sqrt(z^2+r^2)+r*cos(phi)
*(ln(R-r*cos(phi)+sqrt(z^2+r^2+R^2-2*R*r*cos(phi)))-ln(sqrt(r^2+z^2)
-r*cos(phi))),r=0,5);
```

The first integral is obvious, we don't need Maple™ for it:

$$\int\limits_0^{2\pi}\left(\sqrt{z^2+R^2}-z\right)\mathrm{d}\phi=\sqrt{z^2+R^2}-z=2\pi\left(\sqrt{z^2+R^2}-z\right)\tag{12.1.186}$$

For the second term we start using Maple™:

`>int(coeftayl(approx, r=0, 1),phi=0..2*Pi);` Which leads to:

$$\int_0^{2\pi}\left(-\frac{R\cos(\phi)}{\sqrt{z^2+R^2}}+\cos(\phi)\left(\ln\left(R+\sqrt{z^2+R^2}\right)-\ln(z)\right)\right)r\mathrm{d}\phi=0 \tag{12.1.187}$$

Similarly for the third term:

```
>int(coeftayl(approx, r=0, 2),phi=0..2*Pi);
```

Which leads to:

$$\begin{aligned}&\int_0^{2\pi}\left(\sqrt{z^2+R^2}\left(\frac{1}{2}\frac{1}{z^2+R^2}-\frac{1}{2}\frac{R^2\cos^2(\phi)}{\left(z^2+R^2\right)^2}\right)+\cos(\phi)\left(\frac{-\cos(\phi)-\frac{R\cos(\phi)}{\sqrt{z^2+R^2}}}{R+\sqrt{z^2+R^2}}+\frac{\cos(\phi)}{\sqrt{z^2}}\right)-\frac{1}{2}\frac{1}{z}\right)r^2\mathrm{d}\phi\\&=-\frac{1}{2}\frac{R^2\pi}{\left(z^2+R^2\right)^{3/2}}\end{aligned} \tag{12.1.188}$$

Similarly for the fourth term:

```
>int(coeftayl(approx, r=0, 3),phi=0..2*Pi);
```

Which leads to:

$$\begin{aligned}&\int_0^{2\pi}\left(\sqrt{z^2+R^2}\left(\frac{1}{2}\frac{R\cos(\phi)}{(z^2+R^2)}-\frac{1}{2}\frac{R^3\cos^3(\phi)}{\left(z^2+R^2\right)^3}\right)\right.\\&\left.+\cos(\phi)\left(-\frac{1}{2}\frac{1}{z^2}+\frac{1}{2}\frac{\cos^2(\phi)}{z^2}+\frac{\sqrt{z^2+R^2}\left(\frac{1}{2}\frac{1}{z^2+R^2}-\frac{1}{2}\frac{R^2\cos(\phi)^2}{\left(z^2+R^2\right)^2}\right)}{R+\sqrt{z^2+R^2}}+\frac{1}{2}\frac{-\cos^2(\phi)-\frac{R\cos^2(\phi)}{\sqrt{z^2+R^2}}}{\sqrt{z^2+R^2}\left(R+\sqrt{z^2+R^2}\right)}\right)\right)r^3\mathrm{d}\phi\\&=0\end{aligned} \tag{12.1.189}$$

Similarly for the fifth term:

```
>int(coeftayl(approx, r=0, 4),phi=0..2*Pi);
```

Which leads to:

$$\begin{aligned}
&\int\limits_0^{2\pi}\left[\sqrt{z^2+R^2}\left(-\frac{1}{8}\frac{1}{\left(z^2+R^2\right)^2}+\frac{3}{4}\frac{R^2\cos^2(\phi)}{\left(z^2+R^2\right)^3}-\frac{5R^4\cos^4(\phi)}{\left(z^2+R^2\right)^4}\right)+\frac{1}{8}\frac{1}{z^2}\right.\\
&+\frac{\cos(\phi)}{\left(z^2+R^2\right)^3\left(R+\sqrt{z^2+R^2}\right)^2}\left(-\frac{1}{6}\frac{\cos(\phi)}{z^2}+\frac{1}{3}\frac{\left(-1+\cos^2(\phi)\right)\cos(\phi)}{z^3}+\frac{\sqrt{z^2+R^2}\left(\frac{1}{2}\frac{R\cos(\phi)}{\left(z^2+R^2\right)^2}-\frac{1}{2}\frac{R^3\cos^3(\phi)}{\left(z^2+R^2\right)}\right)}{R+\sqrt{z^2+R^2}}\right.\\
&+\frac{1}{3}\frac{\cos(\phi)\left(\frac{1}{2}\frac{1}{z^2+R^2}-\frac{1}{2}\frac{R^2\cos^2(\phi)}{\left(z^2+R^2\right)^2}\right)}{R+\sqrt{z^2+R^2}}+\frac{1}{3}\left(-\left(z^2+R^2\right)^{3/2}z^2-\left(z^2+R^2\right)^{3/2}R^2+\left(z^2+R^2\right)^{3/2}R^2\cos^2(\phi)\right.\\
&+2\cos^2(\phi)z^2R^3+\cos^2(\phi)R^5+\cos^2(\phi)\sqrt{z^2+R^2}z^4\\
&\left.\left.\left.+2\cos^2(\phi)\sqrt{z^2+R^2}z^2R^2+\cos^2(\phi)\sqrt{z^2+R^2}R^4\right)\left(-\cos(\phi)-\frac{R\cos(\phi)}{\sqrt{z^2+R^2}}\right)\right)\right]r^4\mathrm{d}\phi\\
&=\frac{3\pi R^2}{32}\frac{\left(4z^{18}+35R^2z^{16}+131R^4z^{14}+273R^6z^{12}+343R^8z^{10}+259R^{10}z^8+105R^{12}z^6+11R^{14}z^4+8z^2R\left(z^2+R^2\right)^{15/2}-7z^2R^{16}-2R^{18}-2R^3\left(z^2+R^2\right)^{15/2}\right)}{\left(z^2+R^2\right)^{21/2}\left(R+\sqrt{z^2+R^2}\right)^2}\\
&=\frac{3}{32}\frac{R^2\pi\left(4z^4+8z^2R\sqrt{z^2+R^2}+7z^2R^2-2R^4-2R^3\sqrt{z^2+R^2}\right)}{\left(R+\sqrt{z^2+R^2}\right)^2(z^2+R^2)^{7/2}}\\
&=\frac{3}{32}\frac{R^2\pi(2z-R)(2z+R)\left(z^2+2\sqrt{z^2+R^2}R+2R^2\right)}{\left(R+\sqrt{z^2+R^2}\right)^2(z^2+R^2)^{7/2}}\\
&=\frac{3}{32}\frac{R^2\pi(2z-R)(2z+R)\left(R+\sqrt{z^2+R^2}\right)^2}{\left(R+\sqrt{z^2+R^2}\right)^2(z^2+R^2)^{7/2}}\\
&=\frac{3}{32}\frac{R^2\pi(2z-R)(2z+R)}{(z^2+R^2)^{7/2}}=\frac{3}{32}\frac{R^2\pi(4z^2-R^2)}{(z^2+R^2)^{7/2}}
\end{aligned}\tag{12.1.190}$$

So finally:

$$\begin{aligned}
\varphi(r,z)&=-G\sigma\int_0^{2\pi}f(r,\theta,z)\mathrm{d}\phi\cong-G\sigma\int_0^{2\pi}f(r,z;\phi)\mathrm{d}\phi\\
&=-G\sigma\left[2\pi\left(z-\sqrt{z^2+R^2}\right)+\frac{\pi R^2}{2\left(z^2+R^2\right)^{3/2}}r^2+\frac{3}{32}\frac{R^2\pi(R^2-4z^2)}{(z^2+R^2)^{7/2}}r^4+\ldots\right]\\
&=-G\sigma\left[2\pi\left(z-\sqrt{z^2+R^2}\right)+\frac{\pi R^4}{2\left(z^2+R^2\right)^{3/2}}\left(\frac{r}{R}\right)^2+\frac{3}{32}\frac{R^6\pi(R^2-4z^2)}{(z^2+R^2)^{7/2}}\left(\frac{r}{R}\right)^4+\ldots\right]\\
&=\varphi_0(z)+\varphi_2(z)\left(\frac{r}{R}\right)^2+\varphi_4(z)\left(\frac{r}{R}\right)^4+\ldots
\end{aligned}\tag{12.1.191}$$

As there is no angular dependence in re relation above, the field strength becomes:

$$\Gamma=-\operatorname{grad}\varphi(r,z)=\Gamma_r\vec{e}_r+\Gamma_z\vec{e}_z\tag{12.1.192}$$

where:

$$\Gamma_r=-\frac{\partial\varphi}{\partial r},\quad\Gamma_z=-\frac{\partial\varphi}{\partial z}\tag{12.1.193}$$

The components of the gravitational field strength are therefore:

$$\boxed{\begin{aligned}
\Gamma_r&=-G\sigma\left[\frac{\pi R^3}{\left(z^2+R^2\right)^{3/2}}\left(\frac{r}{R}\right)+\frac{3\pi R^5\left(R^2-4z^2\right)}{8\left(z^2+R^2\right)^{7/2}}\left(\frac{r}{R}\right)^3+\ldots\right]\\
\Gamma_z&=-G\sigma\left[2\pi\left(1-\frac{z}{\sqrt{z^2+R^2}}\right)-\frac{3\pi zR^4}{2\left(z^2+R^2\right)^{5/2}}\left(\frac{r}{R}\right)^2+\ldots\right]
\end{aligned}}\tag{12.1.194}$$

Not let us focus on what we may consider as the most interesting case: the field depending or r at a high of $z=0$:

$$\Gamma_r(z=0)=-G\sigma\frac{\pi}{R}r-G\sigma\frac{3}{8}\frac{\pi}{Rr^3}r^3+\mathcal{O}\left(r^4\right) \tag{12.1.195}$$

From these expressions we can readily extract some qualitative information about the behavior of the gravitational field strength of the flat Earth.

The radial component of the gravitational field increases as one moves from the center of the Earth (or from an homogeneous galaxy in the shape of a disc) towards its edge. This changes the magnitude of the field and its direction changes from perpendicular at the center to nearly horizontal at the edge. Therefore, a person tending towards the edge of a flat Earth would need to bend in order to remain in the vertical position.

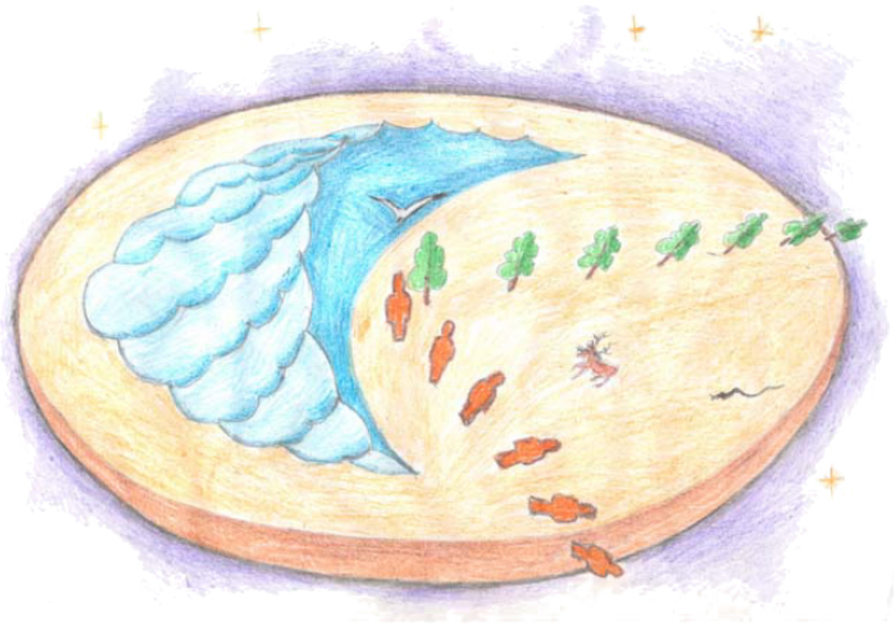

Figure 12.40: **Qualitative picture showing the direction of the gravitational field of a flat Earth (source: [325])**

The series expansions we did earlier give reliable results only at $r\lesssim R/2$. As one approaches the edge of the disc, $r\rightarrow R$, the gravitational field strength grows sharply:

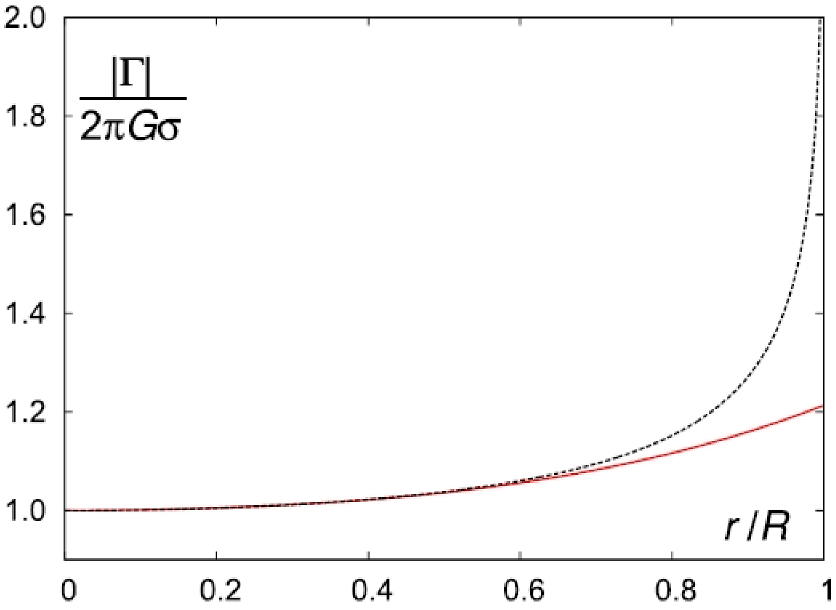

Figure 12.41: **Magnitude of the gravitational field strength at the surface ($z = 0$) where the red solid line corresponds to the calculations according to the series expansions while the black dashed line is the exact result (source: [325])**

Remark

The reader has to keep in mind that the result we get above also applies for a non-rotating disc charged electro-statically in an homogeneous way!

So what we can conclude from these results is that at the opposite of a central gravitational punctual force where the objects that orbits the central one have a speed that decrease proportionally to $1/R$, in the case of a homogeneous disc of matter it seems to be likely that as the radial gravitational force increase rather than decreasing, the orbital speed of objects inside the disc also increase the further we go from the center! We may also imagine (but that would need a rigorous mathematical derivation) that if the disc has a density that decrease slightly the further we go from the center, then things compensate and we may fall back in a in between solution, i.e.: a constant speed! That's obviously just speculation... but may explain the observed "galaxy rotation curve" (as do other models without dark matter like [112]):

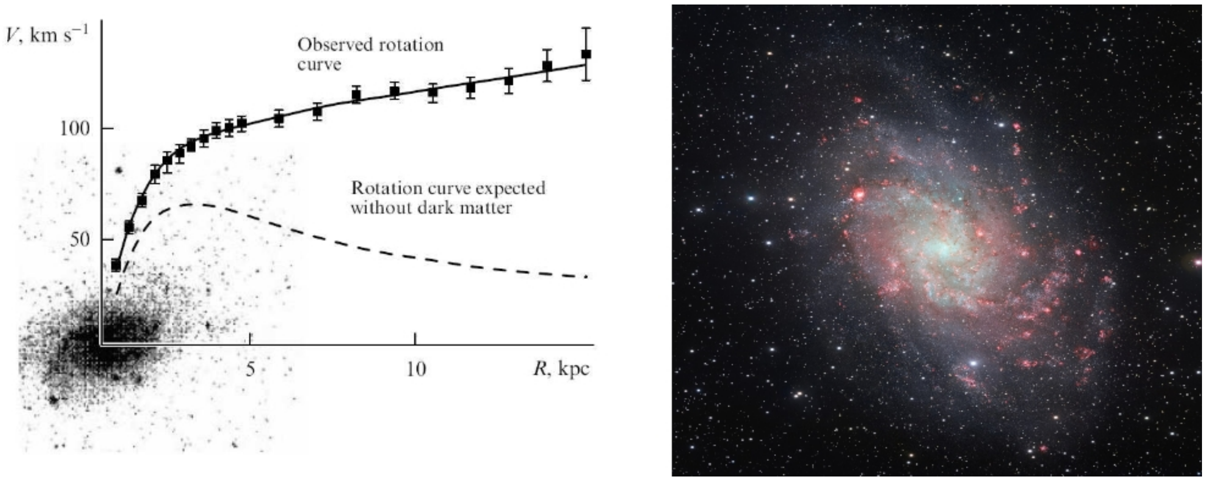

Figure 12.42: **Newtonian expected (with naive central force) vs Observed rotation curve of the M 33 galaxy (source: [594])**

Expecting that galaxies, whose mass resides primarily at large radii, should behave analogously to our Solar System, whose mass resides almost exclusively at its center, seems to us unreasonable!

Here are other galaxies rotation curves:

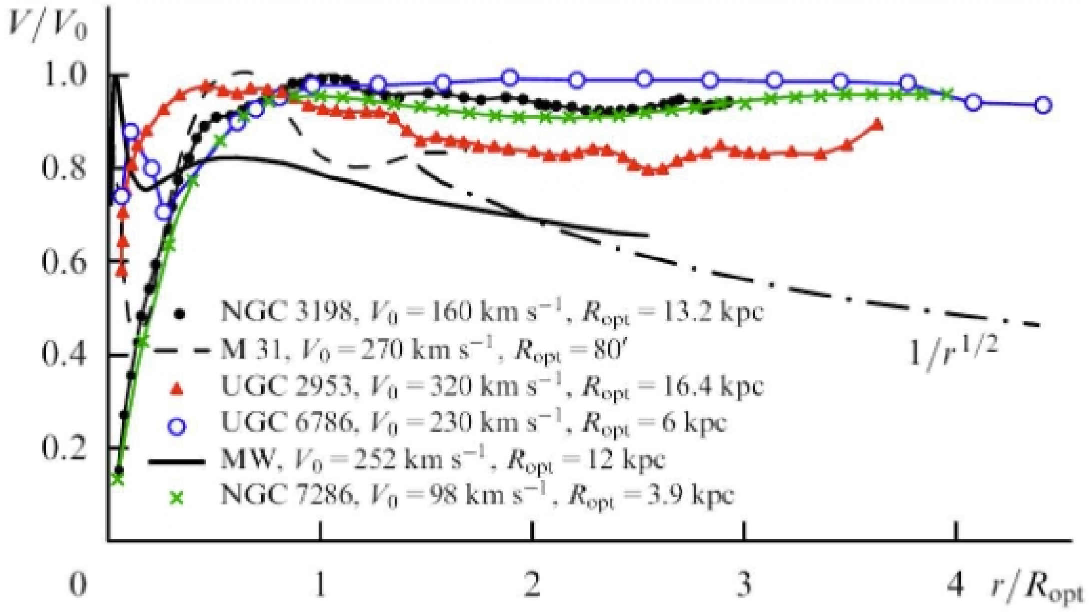

Figure 12.43: **Different galaxies rotation curves (source: [594])**

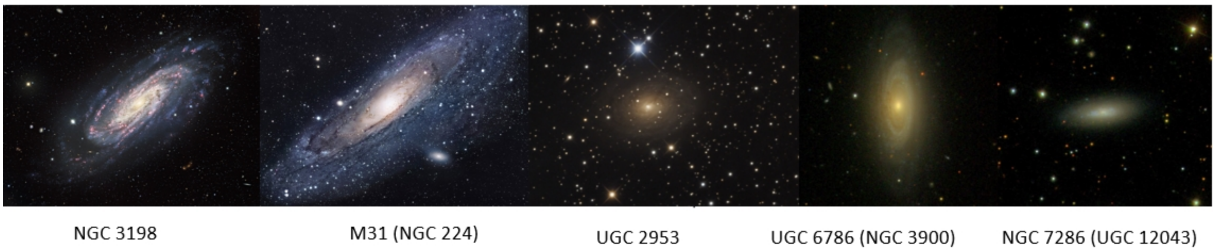
With the corresponding pictures of the different galaxies (obviously we didn't provide any picture of the MW/Milky Way galaxy as we don't have any external picture of it yet...):



The reader can see in a very detailed way at page 469 how looks like the density of stars in a galaxy like M31, or online at the following url (if the web page still exist at the day the reader will try it...):

https://esahubble.org/images/heic1502a/zoomable/

12.1.4.6 Collision time of two objects at rest

Let us consider in an empty space (vacuum) two objects spherical objects A, B of identical mass m and diameter d separated from a distance D and at rest. We want to know after what time they will collide?

We know that the acceleration is given by:

$$\ddot{x}=-\frac{Gm}{r^2} \tag{12.1.196}$$

Let us defined the distance between our two objects by:

$$x_B-x_A\equiv r \tag{12.1.197}$$

Therefore by symmetry:

$$\ddot{r}=\ddot{x}_B-\ddot{x}_A=\ddot{x}_B+\ddot{x}_B=-\frac{Gm}{r^2}-\frac{Gm}{r^2}=-\frac{2Gm}{r^2} \tag{12.1.198}$$

Let us multiple both side by $2\dot{r}$. We then have:

$$2\ddot{r}\dot{r}=\frac{-4Gm}{r^2}\dot{r} \tag{12.1.199}$$

This relation can also be seen as the result of the following relation:

$$\frac{\mathrm{d}}{\mathrm{d}t}\left(\dot{r}^2\right)=\frac{\mathrm{d}}{\mathrm{d}t}\left(\frac{4Gm}{r}\right) \tag{12.1.200}$$

We can integrate both side relatively to the time t, hence:

$$\dot{r}^2+c^{te}=\frac{4Gm}{r} \tag{12.1.201}$$

We have for initial condition:

$$t=0: r=D, \dot{r}=0 \tag{12.1.202}$$

Hence we can easily determine that the constant is given by:

$$c^{te}=\frac{4Gm}{D} \tag{12.1.203}$$

Therefore:

$$\dot{r}^2=4Gm\left(\frac{1}{r}-\frac{1}{D}\right) \tag{12.1.204}$$

Taking the square root (the minus sign is just a matter of convention!):

$$\dot{r}=-2\sqrt{Gm\left(\frac{1}{r}-\frac{1}{D}\right)} \tag{12.1.205}$$

Inverted this give us:

$$\frac{\mathrm{d}t}{\mathrm{d}r}=\frac{-1}{2\sqrt{Gm}\sqrt{\frac{1}{r}-\frac{1}{D}}} \tag{12.1.206}$$

And what we want is obviously integrate the latter:

$$\int \mathrm{d}t=\int_D \frac{-\mathrm{d}r}{2\sqrt{Gm}\sqrt{\frac{1}{r}-\frac{1}{D}}} \tag{12.1.207}$$

Hence we are seeking for the primitive of:

$$\Delta t=\int_D^d \frac{-\mathrm{d}r}{2\sqrt{Gm}\sqrt{\frac{1}{r}-\frac{1}{D}}}=\frac{1}{2\sqrt{Gm}}\int\limits_d^D \frac{\mathrm{d}r}{\sqrt{\frac{1}{r}-\frac{1}{D}}} \tag{12.1.208}$$

Let us do a clever change of variable:

$$\begin{aligned} r&=D\sin^2(\theta)\\ \mathrm{d}r&=2D\sin(\theta)\cos(\theta)\mathrm{d}(\theta) \end{aligned} \tag{12.1.209}$$

Therefore:

$$\Delta t=\frac{1}{2\sqrt{Gm}}\int\limits_d^D \frac{\mathrm{d}r}{\sqrt{\frac{1}{r}-\frac{1}{D}}}=\frac{1}{2\sqrt{Gm}}\int \frac{2D\sin(\theta)\cos(\theta)\mathrm{d}\theta}{\sqrt{\frac{1}{D\sin^2(\theta)}-\frac{1}{D}}} \tag{12.1.210}$$

By our change of variable we also have:

$$\theta=\sin^{-1}\left(\sqrt{\frac{r}{D}}\right) \tag{12.1.211}$$

Hence:

$$\begin{aligned} \Delta t&=\frac{1}{2\sqrt{Gm}}\int\limits_d^D \frac{\mathrm{d}r}{\sqrt{\frac{1}{r}-\frac{1}{D}}}=\frac{1}{2\sqrt{Gm}}\int\limits_{\sin^{-1}\left(\sqrt{\frac{d}{D}}\right)}^{\pi/2} \frac{2D\sin(\theta)\cos(\theta)\mathrm{d}\theta}{\sqrt{\frac{1}{D\sin^2(\theta)}-\frac{1}{D}}}\\ &=\frac{D}{\sqrt{Gm}}\int\limits_{\sin^{-1}\left(\sqrt{\frac{d}{D}}\right)}^{\pi/2} \frac{\sin(\theta)\cos(\theta)\mathrm{d}\theta}{\sqrt{\frac{1}{D\sin^2(\theta)}-\frac{1}{D}}}=\frac{D^{3/2}}{\sqrt{Gm}}\int\limits_{\sin^{-1}\left(\sqrt{\frac{d}{D}}\right)}^{\pi/2} \frac{\sin(\theta)\cos(\theta)\mathrm{d}\theta}{\sqrt{\frac{1}{\sin^2(\theta)}-1}}\\ &=\frac{D^{3/2}}{\sqrt{Gm}}\int\limits_{\sin^{-1}\left(\sqrt{\frac{d}{D}}\right)}^{\pi/2} \frac{\sin(\theta)\cos(\theta)\mathrm{d}\theta}{\sqrt{\frac{1-\sin^2(\theta)}{\sin^2(\theta)}}}=\frac{D^{3/2}}{\sqrt{Gm}}\int\limits_{\sin^{-1}\left(\sqrt{\frac{d}{D}}\right)}^{\pi/2} \frac{\sin(\theta)\cos(\theta)\mathrm{d}\theta}{\sqrt{\frac{\cos^2(\theta)}{\sin^2(\theta)}}}\\ &=\frac{D^{3/2}}{\sqrt{Gm}}\int\limits_{\sin^{-1}\left(\sqrt{\frac{d}{D}}\right)}^{\pi/2} \sin^2(\theta)\mathrm{d}\theta=\frac{D^{3/2}}{\sqrt{Gm}}\int\limits_{\sin^{-1}\left(\sqrt{\frac{d}{D}}\right)}^{\pi/2} \frac{1-\cos(2\theta)}{2}\mathrm{d}\theta \end{aligned} \tag{12.1.212}$$

Assuming:

$$\sin^{-1}\left(\sqrt{\frac{d}{D}}\right)\cong 0 \tag{12.1.213}$$

ie $d\ll D$. Then:

$$\int\limits_{\sin^{-1}\left(\sqrt{\frac{d}{D}}\right)}^{\pi/2}\cos(2\theta)\mathrm{d}\theta\cong 0 \tag{12.1.214}$$

Hence:

$$\Delta t=\frac{D^{3/2}}{\sqrt{Gm}}\int\limits_{\sin^{-1}\left(\sqrt{\frac{d}{D}}\right)}^{\pi/2}\frac{1-\cos(2\theta)}{2}\mathrm{d}\theta\cong\frac{D^{3/2}}{\sqrt{Gm}}\int\limits_{0}^{\pi/2}\frac{1}{2}\mathrm{d}\theta=\frac{D^{3/2}}{\sqrt{Gm}}\frac{\pi}{4} \tag{12.1.215}$$

Therefore (the d has disappeared because remember we assumed $d\ll D$):

$$\boxed{\Delta t\approx\frac{\pi D^{3/2}}{4\sqrt{Gm}}} \tag{12.1.216}$$

For example for two apples of 100 [g] at 1 [meter] of each other, we get $\Delta t\cong 3\times 10^5$ [s] $\cong 3$ [days]. Don't forget that if you want the final speed you just apply the relation derived earlier above:

$$\dot{r}=-2\sqrt{Gm\left(\frac{1}{r}-\frac{1}{D}\right)} \tag{12.1.217}$$

For apples weighing 100 [g], $r=10$ [cm], dropped 1 [m] apart, we get a speed of 5 centimetres per hour.

12.1.4.7 Asteroids/Meteors impact velocity

We have proved in the section of Classical Mechanics that the escape velocity was given by (see page 3234):

$$v_e=\sqrt{\frac{2GM}{r}} \tag{12.1.218}$$

and was therefore independent of the mass m of the ejected object. Obviously the same relation can be applied for an object of mass m coming from an infinite far distance.

For the entry velocity of an asteroid in Earth's atmosphere we can assume that the minimum speed of a colliding asteroid is given by the above escape velocity relation for an asteroid returning to the zero potential of the Earth's gravitational field (a numerical application gives 11 $[\mathrm{km}\cdot\mathrm{s}^{-1}]$.

In fact, their real entering velocity depends on their direction that will determine their relative speed to Earth (which is $30\,[\mathrm{km}\cdot\mathrm{s}^{-1}]$) plus eventually that of the Sun (which is around $200\,[\mathrm{km}\cdot\mathrm{s}^{-1}]$. We can also take into account the escape velocity of the Solar System that is around $200\,[\mathrm{km}\cdot\mathrm{s}^{-1}]$.

The sum gives therefore a speed between $11\,[\mathrm{km}\cdot\mathrm{s}^{-1}]$ (for the optimistic case....) and $300\,[\mathrm{km}\cdot\mathrm{s}^{-1}]$ (for the pessimistic case....) with a statistical peak that gives most observed entry at $30\,[\mathrm{km}\cdot\mathrm{s}^{-1}]$.

As we will prove it in the section of Weather and Marine Engineering (see page 8244) at a height of 600 [m] we can see at a distance of almost 80 [km], then we better understand why it is a joke in some movies to see huge asteroids entering the Earth atmosphere with people looking at it during 10-15 seconds... and waiting almost 1 minute before it hits the ground... (this is type of observation available for meteors but not for asteroids coming from very far!!!).

A good example is to see all the YouTube videos about the small Chelyabinsk meteor (having a diameter of only 20 meters) that entered Earth's atmosphere over Russia on 15 February 12013[10] (holocene calendar) and that had a speed of only almost $30\,[\mathrm{km}\cdot\mathrm{s}^{-1}]$ and which trajectory was visible during almost 20 seconds only with the human eyes (so imagine with a speed 10 times faster...).

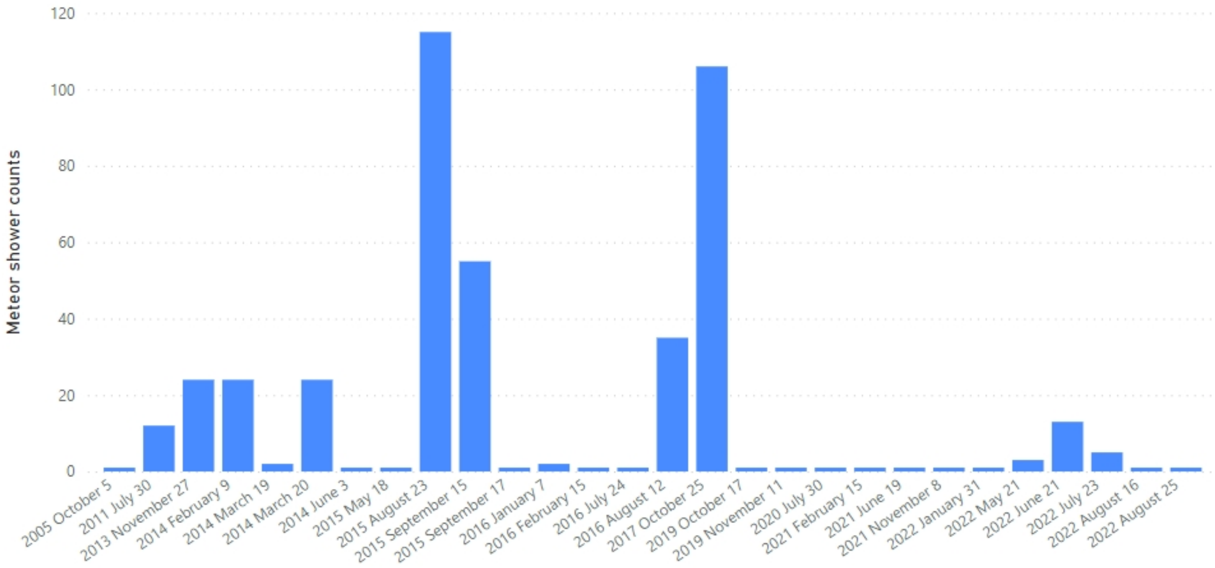
[10] The reader can download the *Meteor Data Center database* of the International Astronomic Union for free on the Internet to see that the days where meteors fall down on Earth is completely random. Some days have meteor showers and some others - not always the same - don't have any meteor shower recorded.

Statistical counts of Meteor shower as given by the Meteor Data Center Database[11]:



12.1.4.8 Spherisation of Celestial Bodies

Thanks to Newton's law, we could answer to a lot of relevant questions in an approximated way and giving us results quite convincing.

A first example is to ask ourself at what scale there is a transition in the domain of irregular shapes (comets, asteroids, moons, etc.) to the field of spheres (moons, planets and stars)? Why the moons of Mars, Phobos and Deimos, have a potato shape like while our Moon is roughly spherical. We will see below that this is due to the mass that is greater in the case of our Moon. Indeed, from a certain mass, arbitrary geometric shapes are not possible anymore.

To address this study, we will first estimate the maximum height of a mountain on a planet. Mount Everest has an altitude of 8.8 [km] while Mount Olympus on Mars has a height of 27 [km]. Why such mountains can not exist on Earth?

To take a simplistic approach, we will assume that a mountain must be in hydrostatic equilibrium. We know experimentally the pressure limit in such a rocks lattice beyond which the rocks begin to "melt" (given in tables): $P_{\text{lim}} \cong 3 \cdot 10^8$ [Pa].

We know from our study of continuum mechanics (see section Continuum Mechanics page 3801) the pressure at the base of a mountain of height h will be given in the hydrostatic approximation by:

$$P_0 = g\rho h \qquad (12.1.219)$$

For the mountain to be stable, it is necessary that:

$$P_0 < P_{\text{lim}} \qquad (12.1.220)$$

---

[11] The huge majority of meteoric dust cannot be observed with actual technologies, so there are no daily available statistics that we can provide here on that specific topic.

and therefore:

$$h < h_0 \tag{12.1.221}$$

Therefore:

$$h_0 = \frac{P_{\text{lim}}}{\rho g} = \frac{P_{\text{lim}} r^2}{\rho m G} \tag{12.1.222}$$

Assuming an average density of $\rho = 3,000\,[\text{kg}\cdot\text{m}^{-3}]$ (continental crust of the Earth) we get:

1. Earth: $h_0 \cong 10\,[\text{km}]$
2. Mars: $h_0 \cong 27\,[\text{km}]$

What is remarkable as approximate result!!!

To estimate the minimum size r_m of a body where the spherical shape becomes predominant compared to the surface deformation (that is to say where gravity has taken over the inter-atomic forces), we will require the size r_m to be greater than the maximum height of a mountain of height h_0. We also assume that the density ρ remains constant through the celestial body. Taking again the relation:

$$h_0 = \frac{P_{\text{lim}} r^2}{\rho m G} \tag{12.1.223}$$

we have:

$$h_0 = \frac{P_{\text{lim}} r^2}{\rho G}\left(\rho\frac{4}{3}\pi r^3\right)^{-1} \tag{12.1.224}$$

hence:

$$h_0 r = \frac{3P_{\text{lim}}}{G 4\pi\rho^2} \tag{12.1.225}$$

The limit r_m can after be estimated by fixing $r = r_m = h_0$ therefore:

$$\boxed{r_m^2 = \frac{3P_{\text{lim}}}{G 4\pi\rho^2}} \tag{12.1.226}$$

obviously for $r \gg r_m$ we will be even closer to the spherical shape.

12.1.4.8.1 Flattening of Celestial Bodies (rotational flattening)

Because of the symmetry of the gravitational potential a star or a planet should have a perfectly spherical form starting a given size, as we have just proved it. Now, the fact is... that it is not so for and especially for telluric bodies!

Because of the own rotation of the star or planet, a centrifugal term transforms the potential. This term depends on the latitude which explains the ellipsoidal shape of most observed celestial bodies.

Let us recall that:

$$a = G\frac{M}{R^2} \tag{12.1.227}$$

where R is the equatorial radius of the star or planet, acceleration to which we have to add the centrifugal acceleration at a given latitude radius r (see section Classical Mechanics page 3291):

$$a_c = \omega^2 r \tag{12.1.228}$$

Therefore the total acceleration given by:

$$a_{\text{tot}} = G\frac{M}{R^2} + \omega^2 r \tag{12.1.229}$$

explains why the Earth is flattened at the poles (or depending of the point of view stretched to the equator ...) and that more one empty planet rotates, the more it will be flattened at the poles.

On Earth, the equatorial radius is of $6,379$ [km] while the polar radius is of $6,357$ [km]. The difference is 22 [km] (hence a difference of approximately 0.34%). The "flattening" of a star or planet is sometimes defined as:

$$\frac{r_e - r_p}{r_e} = \varepsilon \tag{12.1.230}$$

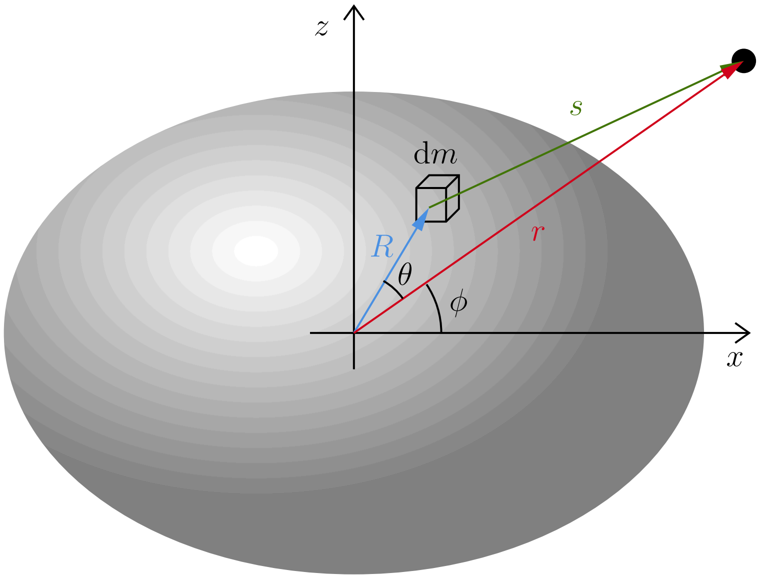
also often denoted f, thus the difference between the equatorial radius and polar radius divided by the equatorial radius (equal to 0.00335 for the Earth).

We can determine approximately an expression of ε (i.e. f) for every rotating celestial body by remembering that the Earth's surface (or another celestial body of important size) is a surface where the potential energy of water is always the same, regardless of its position on the Earth's surface. If this were not the case, water would move towards areas where the energy is lower, thus filling those areas with lower energy.

For this purpose we will work with the apparent potential energy, which is calculated using apparent weight, and us the gravitational energy of a small mass μ near an ellipsoid .

Since the ellipsoid is symmetrical about its axis of rotation, we can orient the x and y axes as we wish (z is in the direction of the ellipsoid's axis of rotation). For simplicity, we will place the mass μ in the x-z plane. The mass μ can be anywhere in this plane. The angle ϕ indicates the angle of the direction of the mass μ with respect to the x-axis.

On the image below, the mass $\mathrm{d}m$ is in the plane x-z, but there are masses $\mathrm{d}m$ outside of this plane:



The gravitational energy of the mass μ exerted by the mass $\mathrm{d}m$ is:

$$\mathrm{d}E_{\text{pot}}=-G\frac{\mu \mathrm{d}m}{s} \tag{12.1.231}$$

As from the law of cosines (see section Trigonometry page 2544):

$$s^2=r^2+R^2-2rR\cos(\theta) \tag{12.1.232}$$

We have:

$$\begin{aligned}\mathrm{d}E_{\text{pot}}&=-G\frac{\mu \mathrm{d}m}{\sqrt{r^2+R^2-2rR\cos(\theta)}}\\&=-\frac{G\mu}{r}\left(1+\frac{R^2}{r^2}-\frac{2R}{r}\cos(\theta)\right)^{-\frac{1}{2}}\mathrm{d}m\end{aligned} \tag{12.1.233}$$

We are going to use a Taylor series (see section Sequences and Series page 1696):

$$(1+x)^{-\frac{1}{2}}=1-\frac{1}{2}x+\frac{3}{8}x^2-\frac{15}{48}x^3+\ldots \tag{12.1.234}$$

and let us keep only the terms up to x^2:

$$\begin{aligned}\mathrm{d}E_{\text{pot}}&=-\frac{G\mu}{r}\left(1-\frac{1}{2}\left(\frac{R^2}{r^2}-\frac{2R}{r}\cos\theta\right)+\frac{3}{8}\left(\frac{R^2}{r^2}-\frac{2R}{r}\cos(\theta)\right)^2+\ldots\right)\mathrm{d}m\\&=-\frac{G\mu}{r}\left(1-\frac{1}{2}\left(\frac{R^2}{r^2}-\frac{2R}{r}\cos(\theta)\right)+\frac{3}{8}\left(-\frac{2R}{r}\cos\theta\right)^2+\ldots\right)\mathrm{d}m\\&=-\frac{G\mu}{r}\left(1-\frac{R^2}{2r^2}+\frac{R}{r}\cos(\theta)+\frac{3R^2}{2r^2}\cos^2(\theta)+\ldots\right)\mathrm{d}m\\&=-\frac{G\mu}{r}\left(1+\frac{R}{r}\cos(\theta)+\frac{R^2}{2r^2}\left(3\cos^2(\theta)-1\right)+\ldots\right)\mathrm{d}m\end{aligned} \tag{12.1.235}$$

Some may recognize that this is a Legendre polynomial (see section Calculus page 1400) expansion of $\cos(\theta)$ which are $1,\cos(\theta),1/2\left(3\cos^2(\theta)-1\right),\ldots$

The potential energy is therefore:

$$\begin{aligned}E_{\text{pot}}&=-\frac{G\mu}{r}\int\left(1+\frac{R}{r}\cos(\theta)+\frac{R^2}{2r^2}\left(3\cos^2\theta-1\right)+\ldots\right)\mathrm{d}m\\&=-\frac{G\mu}{r}\left(\int\mathrm{d}m+\int\frac{R}{r}\cos(\theta)\mathrm{d}m+\int\frac{R^2}{2r^2}\left(3\cos^2(\theta)-1\right)\mathrm{d}m+\ldots\right)\\&=-\frac{G\mu}{r}\left(\int\mathrm{d}m+\frac{1}{r}\int R\cos(\theta)\mathrm{d}m-\frac{1}{2r^2}\int R^2\mathrm{d}m+\frac{3}{2r^2}\int R^2\cos^2(\theta)\mathrm{d}m+\ldots\right)\end{aligned}\tag{12.1.236}$$

We have four integrals to compute:

1. First integral $\int\mathrm{d}m$

   This integral is the sum of the masses of the ellipsoid. This sum is obviously the mass of the ellipsoid M:

   $$\int\mathrm{d}m=M\tag{12.1.237}$$

2. Second integral $\frac{1}{r}\int R\cos\theta\mathrm{d}m$

   The angle θ is the angle between the vector from the center to the mass μ and the vector from the center to the mass $\mathrm{d}m$. To find the cosine of this angle, we will take the dot product between the vectors.

   The components of the vector going from the center of the ellipsoid to the mass μ are:

   $$x_\mu=r\cos(\phi)\quad y_\mu=0\quad z_\mu=r\sin(\phi)\tag{12.1.238}$$

   The components of the vector from the center of the ellipsoid to the mass $\mathrm{d}m$ are x, y, and z. The dot product between the vectors is therefore:

   $$xr\cos(\phi)+zr\sin(\phi)\tag{12.1.239}$$

   This dot product is also equal to (product formula with the magnitudes of the vectors and the angle between the two vectors):

   $$Rr\cos(\theta)\tag{12.1.240}$$

   Equating the two cross products, we have:

   $$Rr\cos(\theta)=xr\cos(\phi)+zr\sin(\phi)\tag{12.1.241}$$

   Hence after simplification:

   $$R\cos(\theta)=x\cos(\phi)+z\sin(\phi)\tag{12.1.242}$$

   We therefore have:

   $$\begin{aligned}\int R\cos(\theta)\mathrm{d}m&=\int(x\cos(\phi)+z\sin(\phi))\mathrm{d}m\\&=\cos(\phi)\int x\mathrm{d}m+\sin(\phi)\int z\mathrm{d}m\end{aligned}\tag{12.1.243}$$

Now, these integrals allow us to find the center of mass of the ellipse at x and at y:

$$\frac{1}{M}\int x\mathrm{d}m = x_{\text{c.m.}} \quad \frac{1}{M}\int z\mathrm{d}m = z_{\text{c.m.}} \tag{12.1.244}$$

Since this center of mass is at the center of the ellipsoid, these integrals are zero. Therefore, we have:

$$\int R\cos\theta\mathrm{d}m = 0 \tag{12.1.245}$$

3. Third integral $\frac{1}{2r^2}\int R^2\mathrm{d}m$

We will show that there is a link between the next two integrals and the moment of inertia of the ellipsoid.

The moment of inertia of an ellipsoid when the axis is in the z direction (direction of the planet's axis of rotation) is:

$$C = \int\left(x^2+y^2\right)\mathrm{d}m \tag{12.1.246}$$

The moment of inertia of an ellipsoid when the axis is in the direction x (one of the directions perpendicular to the axis of rotation of the planet) is:

$$A = \int\left(y^2+z^2\right)\mathrm{d}m \tag{12.1.247}$$

The moment of inertia of an ellipsoid when the axis is in the direction y (the other direction perpendicular to the axis of rotation of the planet) is

$$B = \int\left(x^2+z^2\right)\mathrm{d}m \tag{12.1.248}$$

If we add up the moments of inertia, we have:

$$\begin{aligned}A+B+C &= \int\left(x^2+y^2\right)\mathrm{d}m + \int\left(y^2+z^2\right)dm + \int\left(x^2+z^2\right)\mathrm{d}m\\ &= \int\left(2x^2+2y^2+2z^2\right)\mathrm{d}m\\ &= \int 2R^2\mathrm{d}m\end{aligned} \tag{12.1.249}$$

For an oblate sphere like a planet (a special case of an ellipsoid), A and B are equal. Therefore:

$$\begin{aligned}\frac{1}{2}(A+B+C) &= \int R^2\mathrm{d}m\\ \frac{1}{2}(2A+C) &= \int R^2\mathrm{d}m\end{aligned} \tag{12.1.250}$$

The third integral is therefore:

$$\frac{1}{2r^2}\int R^2\mathrm{d}m = \frac{1}{4r^2}(2A+C) \tag{12.1.251}$$

4. Fourth integral $\frac{3}{2r^2}\int R^2\cos^2\theta \mathrm{d}m$

As (see earlier above):

$$R\cos(\theta) = x\cos(\phi) + z\sin(\phi) \tag{12.1.252}$$

we have:

$$\int R^2\cos^2(\theta)\mathrm{d}m = \cos^2(\phi)\int x^2\mathrm{d}m + \sin^2(\phi)\int z^2\mathrm{d}m + 2\sin(\phi)\cos(\phi)\int xz\mathrm{d}m \tag{12.1.253}$$

There are three parts at this integral.

The first part is:

$$\begin{aligned}\int x^2\mathrm{d}m &= \int\left(x^2+y^2+z^2\right)\mathrm{d}m - \int\left(y^2+z^2\right)\mathrm{d}m\\ &= \int R^2\mathrm{d}m - \int\left(y^2+z^2\right)\mathrm{d}m\\ &= \frac{1}{2}(2A+C)-A\\ &= \frac{1}{2}C\end{aligned} \tag{12.1.254}$$

The second part is:

$$\begin{aligned}\int z^2\mathrm{d}m &= \int\left(x^2+y^2+z^2\right)\mathrm{d}m - \int\left(x^2+y^2\right)\mathrm{d}m\\ &= \int R^2\mathrm{d}m - \int\left(x^2+y^2\right)\mathrm{d}m\\ &= \frac{1}{2}(2A+C)-C\\ &= A-\frac{1}{2}C\end{aligned} \tag{12.1.255}$$

The third part in zero by symmetry:

$$\int xz\mathrm{d}m = 0 \tag{12.1.256}$$

Indeed, the 8 octants of the ellipsoid give the same integral values since they have the same form. However, there are 4 octants where xz is positive and 4 octants where xz is negative.

We have therefore:

$$\int R^2\cos^2(\theta)\mathrm{d}m = \cos^2(\phi)\frac{1}{2}C + \sin^2(\phi)\left(A-\frac{1}{2}C\right) \tag{12.1.257}$$

As:

$$\cos^2(\phi)+\sin^2(\phi) = 1 \tag{12.1.258}$$

we have:

$$\begin{aligned}\int R^2\cos^2(\theta)\mathrm{d}m&=\left(1-\sin^2(\phi)\right)\frac{1}{2}C+\sin^2(\phi)\left(A-\frac{1}{2}C\right)\\&=\frac{C}{2}-\frac{C}{2}\sin^2(\phi)+A\sin^2(\phi)-\frac{C}{2}\sin^2(\phi)\\&=\frac{C}{2}+(A-C)\sin^2(\phi)\end{aligned}\tag{12.1.259}$$

The fourth part is:

$$\frac{3}{2r^2}\int R^2\cos^2(\theta)\mathrm{d}m=\frac{3}{2r^2}\left(\frac{C}{2}+(A-C)\sin^2(\phi)\right)\tag{12.1.260}$$

Now that we have all the values of the integrals, we can find the gravitational energy. Knowing that:

$$\int \mathrm{d}m=M\tag{12.1.261}$$

$$\int R\cos(\theta)\mathrm{d}m=0\tag{12.1.262}$$

$$\frac{1}{2r^2}\int R^2dm=\frac{1}{4r^2}(2A+C)\tag{12.1.263}$$

$$\frac{3}{2r^2}\int R^2\cos^2(\theta)\mathrm{d}m=\frac{3}{2r^2}\left(\frac{C}{2}+(A-C)\sin^2(\phi)\right)\tag{12.1.264}$$

We get:

$$\begin{aligned}E_{\text{pot}}&=-\frac{G\mu}{r}\left(\int\mathrm{d}m+\frac{1}{r}\int R\cos(\theta)\mathrm{d}m-\frac{1}{2r^2}\int R^2\mathrm{d}m+\frac{3}{2r^2}\int R^2\cos^2(\theta)\mathrm{d}m+\ldots\right)\\&=-\frac{G\mu}{r}\left(M+0-\frac{1}{4r^2}(2A+C)+\frac{3}{2r^2}\left(\frac{C}{2}+(A-C)\sin^2(\phi)\right)+\ldots\right)\\&=-\frac{G\mu M}{r}+\frac{G\mu}{2r^3}\left(\left(A+\frac{1}{2}C\right)-3\left(\frac{C}{2}+(A-C)\sin^2(\phi)\right)\right)+\ldots\\&=-\frac{G\mu M}{r}+\frac{G\mu}{2r^3}\left(A+\frac{1}{2}C-\frac{3C}{2}-3(A-C)\sin^2(\phi)\right)+\ldots\\&=-\frac{G\mu M}{r}+\frac{G\mu}{2r^3}\left(A-C-3(A-C)\sin^2(\phi)\right)+\ldots\\&=-\frac{G\mu M}{r}+\frac{G\mu(A-C)}{2r^3}\left(1-3\sin^2(\phi)\right)+\ldots\\&=-\frac{G\mu M}{r}+\frac{G\mu(C-A)}{2r^3}\left(3\sin^2(\phi)-1\right)+\ldots\end{aligned}\tag{12.1.265}$$

Let us remind now as proven in the section of Geometric Shapes that for an ellipsoid (see page 2981):

$$(J_0)_{(\vec{i},\vec{j},\vec{k})}=\begin{pmatrix}\frac{1}{5}M(b^2+c^2)&0&0\\0&\frac{1}{5}M(a^2+c^2)&0\\0&0&\frac{1}{5}M(a^2+b^2)\end{pmatrix}\tag{12.1.266}$$

Hence for an oblate spheroid:

$$\begin{aligned} C &= \frac{2}{5}Ma^2 \\ A &= \frac{1}{2}M\left(a^2+b^2\right) \end{aligned} \tag{12.1.267}$$

where a is the equatorial radius and b is the polar radius of the oblate spheroid (planet). Therefore we have:

$$\begin{aligned} C-A &= \frac{2}{5}Ma^2-\frac{1}{5}M\left(a^2+b^2\right) \\ &= \frac{1}{5}M\left(a^2-b^2\right) \end{aligned} \tag{12.1.268}$$

As the flatness is defined by:

$$f=\frac{a-b}{a} \tag{12.1.269}$$

We have:

$$b=a(1-f) \tag{12.1.270}$$

Hence:

$$\begin{aligned} C-A &= \frac{1}{5}M\left(a^2-b^2\right)=M\frac{a^2-a^2(1-f)^2}{5}=M\frac{a^2-a^2(1-2f)}{5} \\ &= a^2M\frac{1-(1-2f)}{5}=a^2M\frac{2f}{5} \end{aligned} \tag{12.1.271}$$

Hence:

$$E_{\text{pot}}=-\frac{G\mu M}{r}+\frac{G\mu(C-A)}{2r^3}\left(3\sin^2(\phi)-1\right)+\ldots \tag{12.1.272}$$

Can be rewritten:

$$\begin{aligned} E_{\text{pot}} &= -\frac{G\mu M}{r}+\frac{Ga^2\mu Mf}{5r^3}\left(3\sin^2(\phi)-1\right)+\ldots \\ &= -\frac{G\mu M}{r}\left(1-\frac{a^2f}{5r^2}\left(3\sin^2(\phi)-1\right)+\ldots\right) \end{aligned} \tag{12.1.273}$$

We will now find the apparent potential energy, which takes into account the planet's rotation. Apparent weight is different from actual weight because the Earth rotates on its axis, meaning that objects on its surface accelerate.

The apparent weight of an object of mass μ that follows the Earth's rotation (for modern measurements of Earth's rotation and its variations see [102] and [484]) is:

$$\vec{W}_{\text{app.}}=\vec{W}-\mu\vec{a} \tag{12.1.274}$$

Since the acceleration is $a=-\omega^2x\vec{i}$, we have:

$$\vec{W}_{\text{app.}}=\vec{W}+\mu\omega^2x\vec{i} \tag{12.1.275}$$

This apparent weight can be obtained from the following potential energy:

$$\begin{aligned}E_{\text{app.}}&=E_{\text{pot}}-\frac{1}{2}\mu\omega^2x^2\\&=E_{\text{pot}}-\frac{1}{2}\mu\omega^2r^2\cos^2(\phi)\end{aligned}\tag{12.1.276}$$

The apparent potential energy is therefore:

$$E_{\text{app.}}=-\frac{G\mu M}{r}\left(1-\frac{a^2f}{5r^2}\left(3\sin^2(\phi)-1\right)+\ldots\right)-\frac{1}{2}\mu\omega^2r^2\cos^2(\phi)\tag{12.1.277}$$

The Earth's surface has a constant potential energy. The potential energy at the equator must therefore be equal to the potential energy at the poles.

At the equator $(\phi=0°,r=a)$, the energy is equal to:

$$\begin{aligned}E_{0°}&\cong-\frac{G\mu M}{a}\left(1-\frac{a^2f}{5a^2}\left(3\sin^2(0°)-1\right)\right)-\frac{1}{2}\mu\omega^2a^2\cos^2(0°)\\&=-\frac{G\mu M}{a}\left(1+\frac{f}{5}\right)-\frac{1}{2}\mu\omega^2a^2\end{aligned}\tag{12.1.278}$$

At the poles $(\phi=90°,r=b)$, the energy is equal to:

$$\begin{aligned}E_{90°}&\cong-\frac{G\mu M}{b}\left(1-\frac{a^2f}{5b^2}\left(3\sin^2(90°)-1\right)\right)-\frac{1}{2}\mu\omega^2a^2\cos^2(90°)\\&=-\frac{G\mu M}{b}\left(1-\frac{2a^2f}{5b^2}\right)\end{aligned}\tag{12.1.279}$$

Since the two energies must be equal, we can equalize the both $(E_{0°}=E_{90°})$, such that:

$$-\frac{G\mu M}{a}\left(1+\frac{f}{5}\right)-\frac{1}{2}\mu\omega^2a^2=-\frac{G\mu M}{b}\left(1-\frac{2a^2f}{5b^2}\right)\tag{12.1.280}$$

We are lucky because μ can be simplified:

$$-\frac{GM}{a}\left(1+\frac{f}{5}\right)-\frac{1}{2}\omega^2a^2=-\frac{GM}{b}\left(1-\frac{2a^2f}{5b^2}\right)\tag{12.1.281}$$

We have to eliminate a, or b. Let us choose to eliminate b using:

$$b=a(1-f)\tag{12.1.282}$$

Therefore:

$$-\frac{GM}{a}\left(1+\frac{f}{5}\right)-\frac{1}{2}\omega^2a^2=-\frac{GM}{a(1-f)}\left(1-\frac{2a^2f}{5a^2(1-f)^2}\right)\tag{12.1.283}$$

Hence (we distribute the right parenthesis):

$$-\frac{GM}{a}\left(1+\frac{f}{5}\right)-\frac{1}{2}\omega^2a^2=-\frac{GM}{a(1-f)}+\frac{2GMf}{5a(1-f)^3}\tag{12.1.284}$$

Let us assume f is small, then using Maclaurin development at first order:

$$\frac{1}{1-f}\cong 1+f \qquad \frac{1}{(1-f)^3}\cong 1+3f \tag{12.1.285}$$

Hence:

$$-\frac{GM}{a}\left(1+\frac{f}{5}\right)-\frac{1}{2}\omega^2a^2=-\frac{GM(1+f)}{a}+\frac{2GMf(1+3f)}{5a} \tag{12.1.286}$$

Multiplying both sides by $-a$ and dividing by GM:

$$1+\frac{f}{5}+\frac{\omega^2a^3}{2GM}=1+f-\frac{2f(1+3f)}{5} \tag{12.1.287}$$

This is a second order polynomial in f. If we solve it, we get for the two roots:

$$f_{1,2}=\frac{GM+\sqrt{G^2M^2-15GM\omega^2a^3}}{6GM} \tag{12.1.288}$$

If we inject into it the values for the Earth:

$$G=6.6743\cdot 10^{-11}\,[\mathrm{N}\cdot\mathrm{m}^2\cdot\mathrm{kg}^{-2}] \quad M=5.9722\cdot 10^{24}\,[\mathrm{kg}] \tag{12.1.289}$$

$$a=6,378\cdot 10^3\,[\mathrm{m}] \quad \omega=7.2921159\cdot 10^{-5}\,[\mathrm{rad}\cdot\mathrm{s}^{-1}] \tag{12.1.290}$$

We get:

$$f_1\cong 0.3289 \qquad f_2\cong 0.004384 \tag{12.1.291}$$

Modern measurement give $f=0.00334$, so the second root is morel likely the right one, hence an error with the second root of the model of 31%. Considering the number of approximation we did (three Maclaurin series approximations plus a constant density approximation...).

Remark

If we look at:

$$1+\frac{f}{5}+\frac{\omega^2a^3}{2GM}=1+f-\frac{2f(1+3f)}{5} \tag{12.1.292}$$

and we neglect the f^2 in the last parentheses (as f is already small, f^2 is very small and can be removed), we get:

$$1+\frac{f}{5}+\frac{\omega^2a^3}{2GM}=1+f-\frac{2f}{5} \tag{12.1.293}$$

And rearranging we have:

$$\boxed{f\cong\frac{5}{4}\frac{\omega^2a^3}{GM}\cong 0.00432644} \tag{12.1.294}$$

Although an ellipsoid of revolution (oblate spheroid) is the best description for the shape of a planet:

Figure 12.45: **Earth with its atmosphere and oceans**

there are obviously imperfections between the model and the reality for some planets (in particular the terrestrial planets, satellites, and small rocky bodies). The geopotential of real celestial bodies can be shaped in a much more complicated way because of the influences of the visible inhomogeneities on the surface as evidenced by these satellite images of the Earth omitting the liquid parts of it (the deformations are amplified by a factor $100,000$ in the image below!):

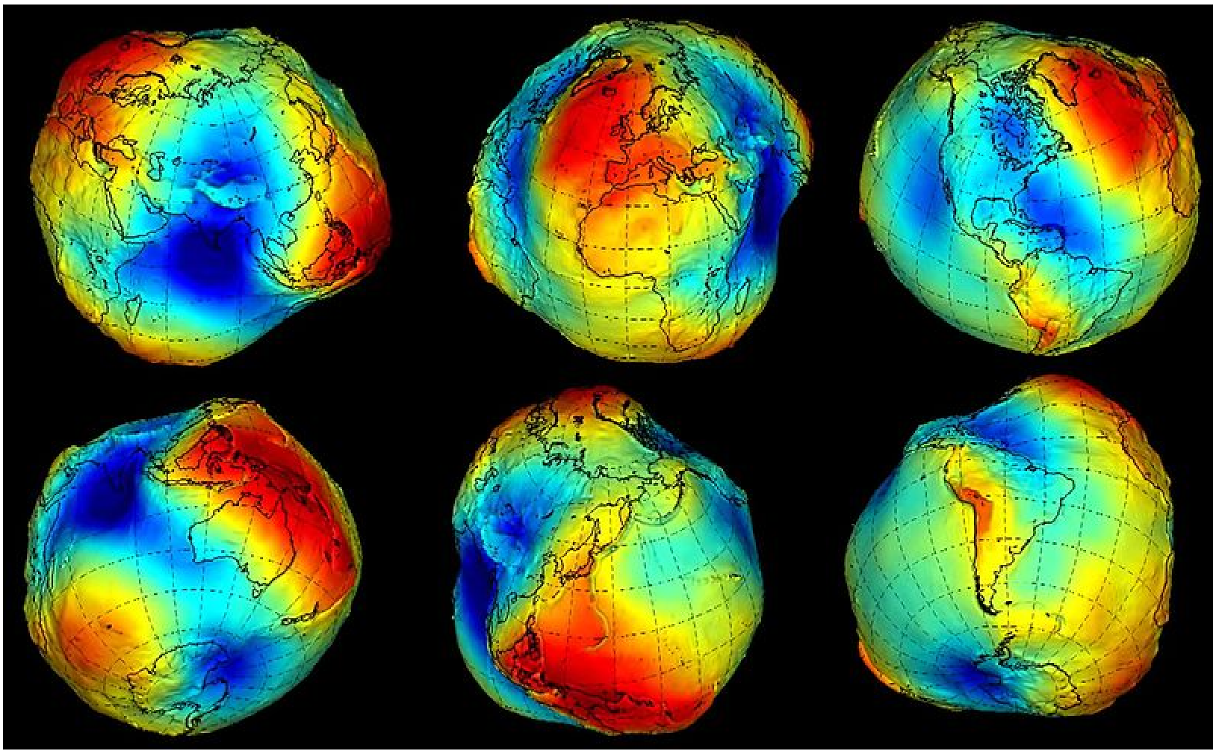


Figure 12.46: **Earth shape without its atmosphere and oceans (source: Wikipedia)**

So the Earth is obviously not a sphere nor Ostrich egg shaped...

The "geoid" is a particular equipotential surface of the Earth's gravity field and serves as a reference for the determination of altitudes. We can imagine the geoid as being the mean sea level extended under the continents.

Considered globally, the geoid deviates from a mathematical reference surface (a rotational ellipsoid) by ±100 meters at most.

Geoid

Figure 12.47: Relationship between geoid, ellipsoid and orthometric elevation (source: SwissTopo)

The specialists of geodesics and of topography have to take into account these inhomogeneities!

Remark

The "Struve Geodetic Arc" is a $2,822$ [km] long chain chain comprised of 12 sections, interspersed between astronomy points, having 10 measured bases, 258 triangles and connecting 259 triangulation points spanning from the north of Norway to the Black Sea (across ten different countries). It was established between 11816 and 11864 (holocene calendar) with the purpose of measuring the flattening of Earth's ellipsoid, and from there the size of the whole globe (since 12005, the points in the triangulation network, including 34 marked with obelisks, have been a UNESCO World Heritage Site). Sadly we were not able to find what was the flatness value obtained by this project...

Because Earth isn't a perfect sphere but rather an ellipsoid, an international consensus for the shape of the best fitted ellipse has been defined under the name `WGS-84` and is used for GPS applications (among others).

Why do we mention this? Because the highest point on Earth's surface measured from sea level is actually the summit of Mount Everest, on the border of Nepal and China with a height of $8,848.86$ [m]. However, the highest point on Earth's surface measured from Earth's center is the summit of Chimborazo in Ecuador, at $6,384.4$ [km] from Earth's centre; the peak's elevation relative to sea level is $6,263.47$ [m]. Because Earth is an oblate spheroid rather than a perfect sphere, it is wider at the equator and narrower toward each pole. Therefore, the summit of Chimborazo, which is near the Equator, is farther away from Earth's centre than the summit of Mount Everest is; the latter is $2,168$ [m] closer, at $6,382.3$ [km] from Earth's centre.

But how do we compute the difference in height between the sphere and the WGS-84 reference ellipsoid as illustrated below:

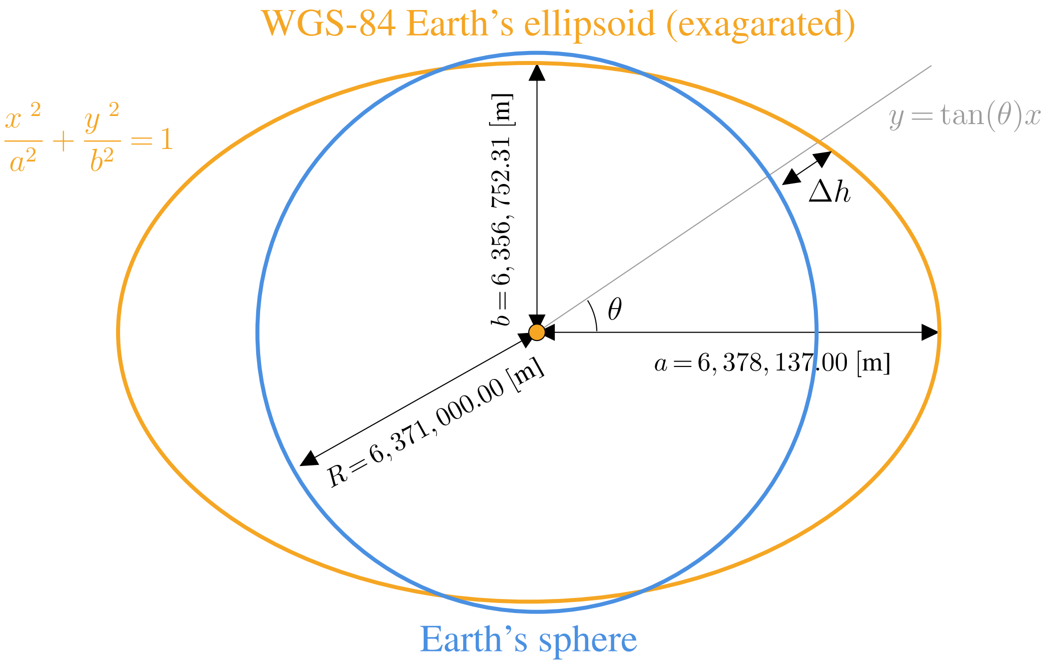

Figure 12.49: Earth's ellipsoid of reference vs the perfect sphere

We start for the ellipse famous equation:

$$\frac{x^2}{a^2}+\frac{y^2}{a^2}=1 \tag{12.1.295}$$

If we want to determine Δh for the angle θ corresponding to a given latitude, we need to find the intersection between the equation of the straight line $y=\tan(\theta)$ and the rearranged equation of the ellipse:

$$y=b\sqrt{1-\frac{x^2}{a^2}} \tag{12.1.296}$$

Thus we seek x for which:

$$\tan(\theta)x=b\sqrt{1-\frac{x^2}{a^2}} \tag{12.1.297}$$

Hence:

$$x^2\left(\tan^2(\theta)+\frac{b^2}{a^2}\right)=b^2 \tag{12.1.298}$$

Hence:

$$x=\frac{b}{\sqrt{\tan^2(\theta)+\dfrac{b^2}{a^2}}} \tag{12.1.299}$$

So finally:

$$\begin{aligned}\Delta h=\sqrt{x^2+y^2}-R^2&=\sqrt{\left(\frac{\tan(\theta)b}{\sqrt{\tan^2(\theta)+\dfrac{b^2}{a^2}}}\right)^2+\left(\frac{b}{\sqrt{\tan^2(\theta)+\dfrac{b^2}{a^2}}}\right)^2}-R^2\\&=\frac{b\sqrt{\tan^2(\theta)+1}}{\sqrt{\tan^2(\theta)+\dfrac{b^2}{a^2}}}-R^2\end{aligned} \tag{12.1.300}$$

Using this result we can found the lowest dry land on Earth relatively to Earth's center in comparison of the lowest one relatively to the sea level (shore of the Dead Sea, shared by Israel, Palestine and Jordan at -432.65 [m]). We can easily found that the dry place with the highest latitude on Earth's at sea level is the northernmost Greenland's costs that is at 0 [m] from sea level but approximately $15,193$ [m] lower than the Dead Sea relatively to Earth's center! Hence the lowest point on Earth's surface (on dry land) relatively to Earth's center is the northernmost Greenland's shore.

Ignoring Earth's shape, until 12019 (holocene calendar), the lowest point on continental Earth relatively to sea level was still believed to be the Dead Sea area with ~ 440 [m] under sea level ([417]). In 12019 (holocene calendar) the lowest point on continental Earth has been identified in East Antarctica under the Denman Glacier where it reaches ~ 3.5 [km] under sea level (see [399]).

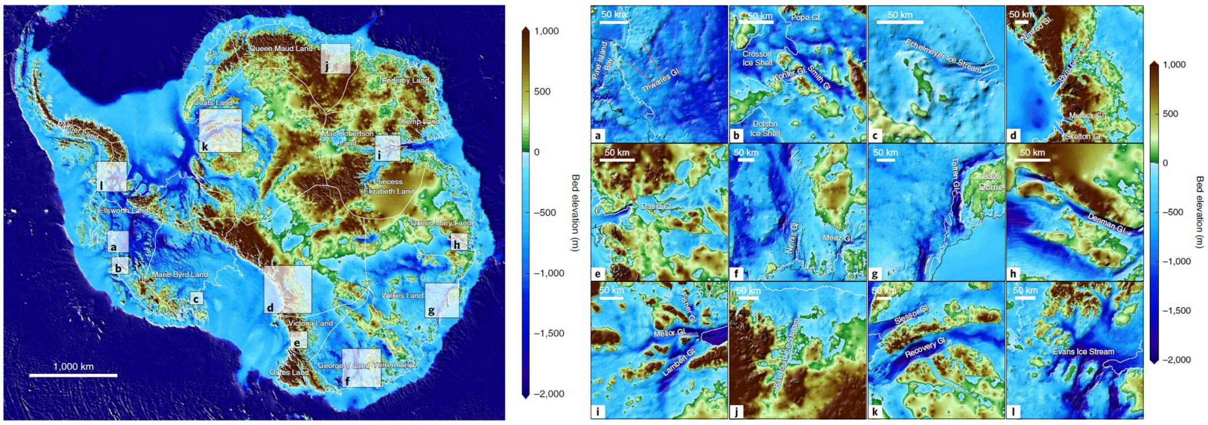

Figure 12.50: **Antarctica topography (source: [399])**

12.1.4.8.2 Empirical evidence that Earth isn't globally flat

Because some people around the world on social networks lie about the shape of the Earth to defend their ignorant religion/sect (indeed it is confirmed in linguistic that the Earth is described as flat in the bible as proven in [195], and also in sunni Islam as proven in quran's 79:30, tafsir Al-Tabari 1/435-436, tafsir Abd Al-Razzaq 3/329 and Sahih al-Bukhari 6520) or to make money by selling books, conferences or by getting more views of their videos, we have sadly to remind a non-exhaustive list of simple empirical evidence that the Earth is a geoid (approximately a sphere/oblate-spheroid) that spins[12]:

1. On a completely flat Earth it would be possible to see distant locations distant from more than 500 kilometers with a telescope even if taking into account light diffusion and absorption. This has never been done because the Earth is curved (see [540]). If the Earth was flat the following locations should also be visible every day from each other however it's not the case: Guilvinec (France)- Foz (Spain)/~ 524 kilometers, Marseille (France) - Perpignan (France)/~ 213 kilometers, Calvi (France)-Nice (France) /~ 175 kilometers, Chicago (USA)-Manistique (USA)/~ 464 kilometers, Sebastopol (Russia)-Burgas (Bulgaria)/~ 538 kilometers, Bangkok (Thailand)-Koh Samui (Thailand)/~ 469 kilometers, Sharm El Sheikh (Egypt)-Assab (Eritrea)/$\sim 1,870$ kilometers... among millions of other places around the World where the flat Earth model doesn't work!

2. All Earth size like bodies in the Solar System (and even much smaller and bigger) seen by telescopes like Hubble, James Webb Telescope and others are seen as geoid (like the Moon, Mars, Mercury, Venus, Uranus, Ganymede, Callisto, Io, Europa, etc.). This is a statistical abductive evidence that the Earth is obviously not globally flat.

3. From a large sea (above 50 kilometres wide for example) and a position at the water level (coast) you can't see the coast from the other side (this implies that boats or offshore windmill farm - like the Thorntonbank Wind Farm in Belgium - at the horizon disappear from the bottom to the top and not shrink uniformly as it would be the case according to the law of perspectives on a flat Earth).

---

[12] We have grouped together evidence of the same type so that the list below is better structured. If we had not done this grouping, the list would have easily exceeded a few thousands or even millions of evidence against the flat Earth.

4. Eratosthenes (ancient Greek polymath: a mathematician, geographer, poet, astronomer, and music theorist) measured the angle of shadow to determine the circumference of the Earth using only two measurement points in Alexandria and Syene as he already knew the Earth is a sphere (in the 98th century according to holocene calendar). Flat earthers are not wrong when they claim the original experiment did not prove the Earth is round. But we can modify the experiment to use three or more measurement points (more than 600 schools on the five continents have carried out more than $6,000$ measurements since 2005 - The Eratosthenes project), and the flat Earth model is instantly proven wrong.

5. The fact that the Sun and Moon appear and disappear from the horizon with a geometry that violates the laws of linear perspective (especially the homographic equations) contradicts a flat Earth model where the Sun and the Moon always remain at a fixed altitude above the flat Earth.

6. Flat earthers can't explain by a mathematical model why we can't see the far side of the Moon (in other words: that we can see only the visible side including the small libration effect) as in their model the Sun and Moon are always above the flat Earth and turn (according to them) around an imaginary barycenter that is located at the North Pole... or that spirals around each other (.........).

7. The National Society of Professional Surveyors (NSPS) require practitioners to take into account an average declination of 8 [cm] per kilometres (see NSPS "Definitions of Surveying and Associated Terms"). The Swiss Geodesy Commission has a similar rule in the Volume 70 of its *Astronomisch-geodätische Arbeiten in der Schweiz*.

8. We have direct non-composite real-color images footage of a geoid Earth from weather satellite like - among others - the Japanese Himawari-8 (the satellite orbits the Earth synchronously in a geostationary orbit at $140°$ East at a distance of $35,786$ [km]).

9. Seismic waves propagation (primary waves, secondary-waves, Rayleigh waves, Love waves, Stoneley waves) after Earthquakes are reflected and propagates in a way that wouldn't work on flat Earth.

10. The LIGO (Laser Interferometer Gravitational-Wave Observatory) research centers had to take into account the curvature of Earth in the design of their detector. This includes the four following detectors: LIGO Hanford/USA, LIGO Livingston/USA, GEO600/Germany, Virgo/Italy.

11. Coriolis effect makes cyclones and oceanic currents spin counter-clockwise north of the equator, but clockwise south of the equator (this is also related to Foucault pendulum or Gyro LASER 15 degree per hour drift (Sagnac effect)), due to the Earth's rotation (for modern measurements of Earth's rotation and its variations see [102] and [484]). Foucault's pendulum proves Earth's rotation but also that it is spherical as the pendulum rotates clockwise in the northern hemisphere and counterclockwise in the southern hemisphere. The pendulum turns faster if it is closer to the pole. On the equator, the pendulum does not rotate.

12. The shadow of Earth on the Moon during a lunar eclipse is always a dark oval that moves from one side of the Moon to the other. The only shape that casts an oval shadow no matter which direction it is pointed is something that is shaped like a sphere. Furthermore, in

the flat Earth model, the position of the Moon and the Sun relatively to the Earth makes it impossible for flat Earthers to explain the origin of the lunar eclipse without involving a third invisible body... They also don't have any mathematical model that can predict the occurence of lunar eclipses as we have for the traditional model.

13. The flat Earth model is also inconsistent with the fact that a given lunar eclipse is only visible from approximately only half of Earth at a time. Furthermore, Flat earthers don't have any mathematical model able to predict the lunar eclipses as we have for the traditional model. Flat earthers can't also provide a mathematical model to predict the path of totality (the area where the eclipse is total) as we have for the traditional model.

14. Tides would exist on a flat Earth as water bulges up a bit as the Moon or Sun pass overhead. However.... there are a number of observational facts that this model doesn't explain like why do high tides happen twice a day generally, as claimed by flat earthers gravity doesn't exist so the observed tides shouldn't exist, why are there two spring and neap tides (larger and smaller tidal ranges) each month approximately and why do the spring tides correlate with full and new Moon? So it would be more accurate to say that a flat Earth shouldn't have tides that act as tides do on Earth. Hence flat Earth is wrong.

15. The stars in the northern hemisphere turn counterclockwise around (approximately) the Polaris (Alpha Ursae Minoris) and in the southern hemisphere clockwise around Polaris Australis (Sigma Octantis) and this is incompatible with the flat Earth model.

16. The meteorites, stars, constellations, nebulae and galaxies visible in the southern hemisphere are not the same as those visible in the northern hemisphere and this is because the Earth is a sphere. The flat Earth can't explain this observational fact.

17. In the Northern Hemisphere, the Sun appears to move to the right. In the Southern Hemisphere, it appears to move to the left. At sunrise and sunset (as commonly named... a better denomination being daybreak/nightfall), the Sun's path is at an angle that roughly corresponds to the observer's latitude. This occurs because observers at different locations on the Earth's surface are not on the same plane. The path of the Sun observed from many different locations on the Earth's surface is proof that the Earth is spherical. This observation cannot occur on a flat Earth.

18. Approximately four months per year there is no night (midnight sun) in respectively the north/south hemisphere and there are plenty of uncut videos providing evidence for people who don't have the money to take holidays in Antarctica. At the exact position of the North pole and South pole the midnight Sun has a duration of six months. This observational fact is incompatible with the flat Earth model.

19. The Sun describes an analemma in the sky during a year can only be explained on a globe (oblate-spheroid) Earth, rotating with a titles axis rotation and in motion around the Sun with an eccentric orbit.

20. The seasons variations of temperature are explained and computed accurately by mathematical models considering a globe (oblate-spheroid) Earth. Flat earthers are not able to provide a coherent mathematical model to explain seasons and also for the Earth equilibrium temperature nor for the diurnal temperature variation...

21. The supposed 0° angle from the North Pole and the 90° angle from the equator on a flat Earth model predicts a Sun which would have to be located essentially next to the surface of the ground of the flat Earth. That's obviously a non-sense!

22. Because the Sun should be next to the surface if the Earth was flat the apparent diameter (angular size) variation of the Sun should be of a few millimetres in a day however flat earthers have never been able to measure such a magnitude using scientific instruments. According to the traditional model the distant Sun angular size varies between 0.524° to 0.5418° (hence a variation of 3.4%) however on the flat Earth model the angular size variation is more than 100% (...) what is obviously incompatible with observational facts.

23. The magnetic field of a flat disc according to the model of flat Earth has never been observed and measured by scientific instruments.

24. The gravity values that would have been measured on different points of a flat Earth are not compatible with the best physical models of gravity (like General Relativity or it's Newtonian approximation) nor with the actual observations.

25. The mathematics of navigation using Global Positioning System (GPS) satellites assume that they are moving in known orbits around an approximately spherical surface. The fact that the GPS (Global Positioning System) uses the WGS84 reference ellipsoid (World Geodetic System 1984) for the conversion between NED (North-East-Down) and LLA (Latitude, Longitude and Altitude) coordinates is a factual evidence that Earth isn't flat.

26. Satellites, including communications satellites used for television, telephone, and Internet connections, would not stay in orbit unless the modern theory of gravitation were correct and the latter describe for Earth an oblate-sphere shape and not a flat Earth.

27. Large bridges like the towers of the Humber Bridge, although both vertical with respect to gravity, are 36 millimetres farther apart at the top than the bottom due to Earth's curvature (other bridges like the Causeway Bridge at Lake Pontchartrain, Louisiana in USA, the Akashi Kaikyo Bridge, the Verrazano Bridge and many others provide counter evidence for a flat Earth).

28. During the construction of the LHC (Large Hadron Collider at CERN, Geneva/Switzerland), the SPS (Super Proton Synchrotron), the Tevatron (Fermilab, Illinois/USA), the KEK (japan), the Relativistic Heavy Ion Collider (RHIC) and the SLAC (Stanford Linear Accelerator Center, California/USA) accelerators the curvature of the Earth had to be taken into account to satisfy the precision constraints of the particles beams.

29. The existence of Time Zones is another evidence that the Earth is approximately an oblate-spheroid. Indeed, for example, in the flat Earth model, the Sun is often depicted as moving in a circular path above the Earth. This would mean that all locations would experience sunrise and sunset at the same time, eliminating the concept of time zones.

30. Having the total height of about 829.8 meters, Burj Khalifa is the tallest building in the world (located in Dubai, United Arab Emirates) at the day we write these line. It is so tall that we can observe the sunset at the base of the building, then rush to the upper floors and watch the same sunset again for the second time on the same day and this is possible because the Earth isn't flat (Burj Khalifa has two observation desks where you can view

sunset twice in the same evening an special tickets named "Sunset tours" are sold on this purpose). Furthermore, the Burj Khalifa has different official Islamic prayer time (three different prayer and iftar time zones) depending on the floor level because the Earth isn't flat! On the higher floors, the Sun is seen for several minutes after it has set at ground level. Those living above the 80th floor have to wait two extra minutes to break their Ramadan fast, and those living above the 150th floor have to wait three minutes for the same reason.

31. The fact that some mountains/places that should be below the horizon because of their distance are visible only a few days per year (because of special atmospheric condition and Sun position) is compatible with the best mathematical geometric optic models but with none of the flat Earth.

32. The time-distance travelled by airplanes (like the Qantas direct flight route QFA63 or QFA64 between Johannesburg in South Africa and Sydney in Austrial), cruise boats (like the MSC Grand Voyage cruise on the MSC Poesia between Barcelona in Spain and Santos in Brazil) or animals (like the white sharks Nicole and Lydia tagged with a GPS respectively in the years 12004 and 12013 according to holocene calendar) are incompatible with a flat Earth.

33. Companies that put submarine copper cables or optical fiber cables have to minimize the distance to optimize the costs. The submarine cables length are incompatibles with a flat Earth. For example the cable between Sydney (Australia) and Perth (Australia) is $4,850$ kilometres long according to his owners (superloop, singTel, Google, Indosat, Oooredoo, AARNET) and follow the shore line. However the shortest path line on the flat Earth map is $8,300$ kilometres between Sydney and Perth.

34. Some commercial airplanes company fly over Antarctica and this wouldn't be possible on a flat Earth. For example on July 14, 12023 (holocene calendar), Qantas Flight QF28 between Santiago de Chile and Sydney rerouted from the usual path and instead went over Antarctica. The flight typically passes over the Southern Pacific Ocean only as far south as 70° south. Nonetheless, that day, the crew flew to 74.17° south to avoid strong headwinds along the usual route. This wouldn't have been possible on a flat Earth.

35. A flat disc like planet contradicts the isoperimetric inequality theorem (for reminder it is based on the Lagrangian). Indeed, the laws of our observable universe (principle of least action) constraints the shape of viscous objects to minimize their surface area for a given volume, leading to a spherical shape in three dimension. This is a direct application of the isoperimetric inequality in three dimensions, where the sphere has the smallest surface area for a given volume.

36. Antarctica was crossed by multiple scientific teams starting from opposite coasts and who encountered at the center of the continent (Commonwealth Trans-Antarctic Expedition) and it was also crossed by extreme sportmen (Norwegian Liv Arnesen and the American Ann Bancroft). This wouldn't have been possible on a flat Earth.

37. The Moon shows its same side (tidal locking) - including libration effect - whatever the position of the observer on Earth and the same time for all observers on Earth and that's not possible on a flat Earth.

38. The face of the Moon is inverted between the northern hemisphere and the southern hemisphere (hence the observation that Moon phase angle varies depending on the latitude at a same moment) and this also can't be explained on a flat Earth.

39. The tilt of the Moon which changes during the day in a clockwise or counterclockwise manner depending on the hemisphere is incompatible with the flat Earth model.

40. The sundial that works all year correctly when the inclination of the needle corresponds to the latitude is once again an evidence against the flat Earth. This corresponds also to the fact that the angle to Polaris approximately corresponds to the latitude of the observer. This fact is observed on every location on Earth where Polaris is visible. By tracing the path to Polaris from multiple locations on the flat model, the lines will not point to a consistent position of Polaris. The reason is that Earth is a sphere and the flat Earth is a sphere and the flat Earth model does not represent reality.

41. The four LIGO experiments localization in USA and Europe (separated from a few thousands of kilometres) provide evidence thanks to time-distance measurements that gravitational waves propagation don't go through a flat Earth but trough an oblate-spheroid Earth.

42. Extending vanishing point of parallels roads from various cities in the World from aerial photos converge to a point in the sky rather to a point at the horizon. This observational fact is against a flat Earth model. A famous well known case of easily observable vanishing point at the ground level and that is incompatible with a flat Earth is the lake Pontchartrain Transmission line (USA) where 85 aligned power transmission towers cross a lake 24.27 kilometers across. If the Earth is flat, the vanishing point of the transmission towers should intersect the horizon but in reality anyone can see that the vanishing point is above the horizon.

43. The Sun always "rises" (...) in the East and always "sets" (...) in the West, in both the southern and northern hemispheres. But the difference is that it is shifted South at noon when you are in the northern hemisphere, and shifted North at noon when you are in the southern hemisphere and this isn't possible on flat Earth.

44. Because the Earth is an oblate-spheroid, the horizon lies below the eye level. The angle between the eye level and the horizon is the "dip of the horizon". The dip is larger as we go higher and this factual observation contradicts a flat Earth model. In the 111th century (according to holocene calendar), Abu Rayhan Muhammad ibn Ahmad al-Biruni (Iranian muslim scholar and polymath during the islamic golden age) determined the radius of the Earth by measuring the dip of the horizon from the top of a mountain at Nandana in Pind Dadan Khan (present-day Pakistan) with a 20% accuracy (the method and assumptions are different of that of Eratosthenes).

45. The flat earthers are unable to provide a mathematical model to explain the apparent change of color of the Sun at sunset (red sunset) including the famous green flash. However in the traditional model of the Earth (oblate sphere), this both phenomenon are clearly computable by Rayleigh scattering and because the Sun is below the horizon (i.e. behind the curvature!).

46. The Deep Underground Neutrino Experiment (DUNE) time lap between the Fermi National Accelerator Laboratory in Batavia, Illinois (USA) and the Sanford Underground

Research Laboratory in Lead, South Dakota (USA) - $1,300$ kilometers downstream of the source - can be explained only on an oblate-spheroid Earth. The T2K experiment neutrino oscillation experiment, sending a muon neutrino beam from J-PARC proton accelerator on the east coast of Japan to Super-Kamiokande located 295 kilometers away, close to the west coast of Japan lead to the same conclusion and same for the CNGS project between the CERN Geneva (Switzerland) SPS (Super Proton Synchrotron) accelerator to Grand Sasso (Italy) apart from 732 kilometers. The difference between the neutrino travel times and the speed of light over the 732 [km] beam path was measured to be -1.9 ± 3.7 nanoseconds, consistent statistically with zero difference (see [5]). In this case, if a flat Earth model had been used, the beam path distance would be equal to the surface distance from CERN to Gran Sasso, again about 410 metres longer. This would have given the neutrino travel time difference to be an extra $410/c=1370$ [ns], making the neutrinos travel significantly faster than the speed of light.

47. As for the human eye that sees using electromagnetic wave, standard radars can't see objects below the horizon in standard atmospheric conditions. To see below the horizon engineers have to use OTHR (Over The Horizon Radars) that bounce the signal on the ionosphere and the time propagation signal is compatible with an oblate-spheroid and not with a flat Earth.

48. The rocket engineers of the spatial agencies Roscosmos (Russia), JAXA (Japan Aerospace Exploration Agency), ESA (European Space Agency), CNSA (China National Space Administration), ISRO (Indian Space Research Organization), ISA (Israel Space Agency), ISA (Iranian Space Agency), United Kingdom Space Agency (UKSA), NATA (North Korean Space Agency), KASA (Korea AeroSpace Administration), SSAU (State Space Agency of Ukraine) and NASA (National Aeronautics and Space Administration) all confirm observations of a geoid Earth based on their independent rockets launch technologies and independent satellites.

49. There is experimental evidence based on atomic clocks that the spin of the Earth slows down. This result is incompatible with the claim of flat earthers that the Earth doesn't spin.

50. Aircrafts artificial horizons have self correcting mechanisms to constantly and rapidly correct alignment drift with the horizon and this necessity is necessary because the Earth is curved.

51. Armies have to integrate into the ballistic equations the rotation and curvature of Earth to reach their targets (among other parameters like weather conditions and gravity magnitude depending on the altitude). This wouldn't be necessary on a flat and non-rotating Earth.

52. At places of comparable latitude North and South, the Sun behaves very differently than it would on a non-spinning flat Earth or on a spinning flat Earth. For example, the longest summer days North of the equation are identical than those South of the equator (same for shortest day) and this isn't possible on a flat Earth but is compatible with a geoid Earth.

53. Plenty of constellations cannot be seen in the northern hemisphere and respectively in the southern hemisphere and this is incompatible with a flat Earth.

54. The diurnal tidal bulge (due to the Moon) is compatible only with a spherical like Earth shape (oblate-spheroid) and totally incompatible with a flat Earth.

55. All sailors and pilots in the world know that the Earth is curved because the international definition of the "nautical mile" takes into account the curvature of the Earth and only works on a spherical Earth and not on a flat one.

56. The Antarctica Cup Yacht Race is a race that turns clockwise around the Antarctica continent by maintaining a regular South-East cap. That wouldn't be possible on a flat Earth.

57. The Blasius boundary layer fluid mechanics model explains how and why the atmosphere rotates with a spinning Earth. Flat earthers claim at the opposite that there are no models able to explain the atmosphere rotation of a spinning oblate-spheroid Earth.

58. North/South circumnavigation were done multiple times by people with airplanes (Sir Ranulph Fiennes in 11979 - holocene calendar, Rockwell Polar Flight in 11965 - holocene calendar, TAG TransPolar 08 in 12009 - holocene calendar and One More Orbit in 12019 - holocene calendar). That's evidence Earth isn't flat.

59. During a solar eclipse the Sun and Moon are on the same axes and cast an irregular elliptical shadow on Earth. However on a flat Earth the shadow would be a circle. Therefore Earth isn't flat.

60. We have Aurora Borealis in Arctica because magnetic field lines are concentrated there. However we have also have Aurora Australis in Antarctica because magnetic field lines are concentrated there. This works only with the geoid Earth model as for flat earthers the magnetic field diverges in Antarctica.

61. The measured time-distance propagation of radio-wave signals (remember that electromagnetic waves travel at constant speed in a given medium, i.e. the speed of light in this medium!) is incompatible with those given in the flat Earth model however almost perfectly compliant with those given on a geoid Earth.

62. The results of the Hafele-Keating experimental test of Special Relativity is incompatible with the non-spinning Earth model (because of the measure speed relativistic effect component) but also incompatible with the gravitational field shape of a flat Earth (because of the measure of the gravitational relativistic effect component).

63. On 14 January, 12022 (holocene calendar), the volcano Hunga Tonga erupted explosively. Soon after, meteorological stations across the world were recording changes in barometric pressure due to the shockwave. The time-distance (at the speed of sound) of these shockwaves and the fact that at the antipodal shock-wave position (Algeria) the shock-wave has converged and produced a second opposite shockwave has been recorded. These both evidence all contradict the model of flat Earth.

64. Radio waves generated by lightning flashes in storm are (among others) electromagnetic waves with a frequency of 7.8 [Hz] that are travelling around the world in the waveguide formed by the Earth and the ionosphere, and returning one wavelength later to constructively interfere and reinforce themselves, producing a measurable peak in Earth's magnetic field fluctuations. The Irish physicist George Francis Fitzgerald first anticipated the existence of this effect named "Schumann resonances" in 11893 (holocene calendar),

but his work was not widely circulated. Around 11950, (holocene calendar) the German physicist Winfried Otto Schumann performed the theoretical calculations that predicted the resonances may be observable, and made efforts to observe them. But it was not until 11960 (holocene calendar) that Balser and Wagner made the first successful observations and measurements of Schumann resonances (see [39]). If the Earth was flat, then any ionosphere above it would be flat as well, and would still form a waveguide for low frequency radio waves. However it would not be a closed waveguide. Radio waves would propagate out the edges and be lost to space, meaning there would be no observable magnetic field resonances at all. And even if there were an opaque radio wall of some sort at the edge of the flat Earth, the size and geometry of the resulting cavity would be different, resulting in a different set of resonance frequencies.

65. There are more than twenty different models of the flat Earth (with or without dome, infinite or finite disc radius, different thickness of the disc, different height for the Sun and the Moon, that spin or doesn't spin, etc.) that all disagree with each other because there is zero experimental evidence for any flat Earth model. Hence all the flat Earth models are just a delusional belief of trolls, or bigots, or mentally ill, or business-seekers, or uneducated individuals.

66. In most flat Earth models the light of the Sun and the light of other stars are strongly bended/deflected in some situations for some observers every day! The magnitude of this daily supposed deflection magnitude of the light (sometimes near 90°) hasn't been modelled by any consistent and conclusive theoretical atmospheric model nor validated experimentally by flat earthers and is not only incompatible with classical actual atmospheric model but also incompatible with the gravitational Newtonian deflection of light or the gravitational General Relativity deflection of light.

67. The Earth-Moon barycentre isn't aligned with the Earth center. The result of this is that during a full Moon, when the Moon is farthest from the Sun, the Earth is $4,670$ [km] closer to the Sun than average, whereas during a new Moon the Earth is $4,670$ [km] further away from the Sun than average. The Earth oscillates over $9,000$ [km] towards and away from the Sun every month! And the increase in incident radiation from the Sun during the phases around the full Moon comes to about 43 [mW] per square metre, or an extra $5,450$ [GW] over the entire Earth. The Earth normally receives nearly 44 million giga-Watts of solar radiation, so the difference is relatively small, but it's enough to heat the Earth by almost 0.01 degrees Celsius, which is near the observed average monthly temperature variation (see [21]). This is incompatible with the flat Earth model where the Sun is at a fixed height only a few thousand kilometre above the ground. And if the Sun in the flat Earth model would change its height then it would be an easily observable effect from the surface of the flat Earth (and this has never been observed obviously...).

68. The Eötvös effect discovered in 11900 (holocene calendar) is the change in measured Earth's gravity caused by the change in centrifugal acceleration resulting from eastbound or westbound velocity by the ships, airplanes, submarines measuring Earth's gravity (see [165]). When moving eastbound, the object's angular velocity is increased (in addition to Earth's rotation), and thus the centrifugal (fictional) force also increases, causing a perceived reduction in gravitational force. If the Earth was flat, on the other hand, there would be no Eötvös effect at all. If the flat Earth is not rotating (as most models posit, with the Sun moving above it in a circular path), obviously there is no centripetal acceleration

happening at all. Even if you adopt a model where the flat Earth rotates about the North Pole, the centripetal acceleration at every point on the surface is parallel to the surface, towards the pole, not directed downwards. So an Eötvös-like effect would actually cause a slight deflection in the angle of gravity, but almost zero change in the magnitude of the gravity. The Eötvös effect shows that not only is the Earth rotating, but that it is rotating about a central point that is underneath the ground, not somewhere on the surface. If you stand on the equator and face east, the surface of the Earth is rotating in the direction you are facing and downwards, not to the left or right. Furthermore, the cosine term shows that at equal latitudes both north and south, the rotation is at the same angle relative to the surface, which can only be the case if the Earth is symmetrical about the equator: i.e. spherical.

69. The French space agency CNES launched the SPOT 1 satellite in 11986 (holocene calendar) into a Sun-synchronous polar orbit, meaning it orbits around the poles and maintains a constant angle to the Sun, as the Earth rotates beneath it. This brought any point on the surface into the imaging field below the satellite every 26 days. SPOT 1 took multiple photos of areas of Earth in different orbital passes, from different locations in space. These images could then be analysed to match features and triangulate the distances to points on the terrain, essentially forming a stereoscopic image of the Earth's surface. This reveals the height of topographic features: hills, mountains, and so on. However stereoscopic heights deduction disagree with ground measurement because of Earth curvature (see [236]). Correction has to been added to counter Earth curvature. This is another evidence against a flat Earth model.

70. Artificially produced skyglow appears prominently in the sky above cities. It makes the whole night sky as seen from within the city brighter, making it difficult or impossible to see fainter stars. The skyglow from a city can be seen from dark places up to hundreds of kilometres away, as a dome of bright sky above the location of the city on the horizon. However, although the skyglow from a city can be seen from such a distance, the much brighter lights of the city itself cannot be seen directly – because they are below the horizon. The fact that you can observe the fainter glow of the sky above a city while not being able to see the lights of the city directly is because of the curvature of the Earth. This is not the only effect of Earth's curvature on the appearance of skyglow; it also effects the brightness of the glow. In the absence of any scattering or absorption, the intensity of light falls off with distance from the source following an inverse square law. Physically, this is because as we know the surface area of spherical shells of increasing radius from a light source increase as the square of the radius. In 11977, Merle F. Walker of Lick Observatory in California published a study of the sky brightness caused by skyglow at varying distances from several southern Californian cities (see [566]). He found an empirical relationship that the intensity of skyglow varies as the inverse of distance to the power of 2.5. This relationship, known as "Walker's law", has been confirmed by later studies, with one notable addition. It only holds for distances up to 50-100 kilometres from the city. When you travel further away from a city, the intensity of the skyglow starts to fall off more rapidly than Walker's law suggests, a little bit faster at first, but then more and more rapidly. This is because as well as the absorption effect, the scattered light path is getting longer and more complex due to the curvature of the Earth. A later study by prominent astronomical light pollution researcher Roy Henry Garstang published in 1989 examined data from multiple cities in Colorado, California, and Ontario to produce a more detailed model of the intensity of skyglow (see [196]). The model was then tested

and verified for multiple astronomical sites in the mainland USA, Hawaii, Canada, Australia, France, and Chile. Importantly for our perspective, the model Garstang came up with requires the Earth's surface to be curved. Interestingly, Garstang also calculated a model for the intensity of skyglow if you assume the Earth is flat ! He did this because it greatly simplifies the geometry and the resulting algebra, to see if it produced results that were good enough. However, quoting directly from the paper: *In general, flat-Earth models are satisfactory for small city distances and observations at small zenith distances. As a rough rule of thumb we can say that for calculations of night-sky brightnesses not too far from the zenith the curvature of the Earth is unimportant for distances of the observer of up to* 50 *[km] from a city, at which distance the effect of curvature is typically* 2%. *For larger distances the curved-Earth model should always be used, and the curved-Earth model should be used at smaller distances when calculating for large zenith distances. In general we would use the curved-Earth model for all cases except for city-center calculations. [...] As would be expected, we find that the inclusion of the curvature of the Earth causes the brightness of large, distant cities to fall off more rapidly with distance than for a flat-Earth model.*

71. Before sunrise or after sunset the Sun is low below the horizon, but the sunlight can reach the clouds above. If there is a mountain between them, it can cast a shadow on the clouds (multiple testimonies and photos of this phenomenon are available on the Internet). This is impossible to occur on a flat Earth and can only happen if the Earth is spherical.

72. The rocket engineers in the northern hemisphere and those in the southern hemisphere (Roscosmos (Russia), JAXA (Japan Aerospace Exploration Agency), ESA (European Space Agency), CNSA (China National Space Administration), ISRO (Indian Space Research Organization), ISA (Israel Space Agency), ISA (Iranian Space Agency), United Kingdom Space Agency (UKSA), NATA (North Korean Space Agency), KASA (Korea AeroSpace Administration), SSAU (State Space Agency of Ukraine) and NASA (National Aeronautics and Space Administration)) definitely want to build their launch facilities as close to the equator as practically possible. And this is a consequence of the fact that the Earth is a rotating globe to spare fuel (and therefore money). On the other hand, if the Earth was flat and non-rotating (as is the case in the most popular flat Earth models), there would be no incentive to build your launch facility anywhere compared to anywhere else, and equatorial locations would not be so coveted. And if the Earth was flat and rotating around the north pole, then you would get your best bang for buck not near the equator, but near the rim of the rotating disc, where the linear speed of rotation is highest. If that were the case, then everyone would be clamouring to build their launch sites as close to Antarctica as possible, which is clearly not the case in the real geoid world.

73. Observations of aurorae have established that they occur in nearly-circular elliptical rings of width equivalent to a few degrees of latitude (i.e. a few hundred kilometres), usually between 10° and 20° from the Earth's magnetic poles. These rings, in the northern and southern hemispheres, are named "auroral ovals". An oval aurora cannot happened on a flat Earth model.

74. Gegenschein is a faintly bright spot in the night sky centered at the antisolar point. The backscatter of sunlight by interplanetary dust causes this optical phenomenon, being a zodiacal light and part of its zodiacal light band. If the Earth is spherical, then night time

corresponds to the Sun being behind the planet. You should see, in the night sky, the point exactly opposite the direction of the Sun. You should be able to see, in that direction, the backscattered light of the Sun from the interplanetary dust cloud. Now let us imagine the Earth is flat. The Sun shines on some part of the Earth at all times, so therefore it must be above the plane of the Earth at all times. At any rate, it should never be possible to look into the sky in the exact opposite direction to the Sun. So there should be no point in the night sky with a peak of backscattered sunlight.

75. From an observation point on Earth, we can watch for meteors. Better than counting by eye, professional astronomers have built specialised radar systems that can detect meteors with greater sensitivity, including during daylight hours, and we can set them up counting meteors all day, every day. Every time the radar detects a meteor, it can record where in the sky it was, what direction it moved, and what time the event occurred. Thinking about the time in particular, we can count how many meteors arrive during any given hour, and average this over many days to produce an hourly rate of meteor events. Many experiments do just this. If the Earth is a rotating geoid in space, orbiting around the Sun, we should expect that the dawn part of the Earth, where the local time is around 6am, should sweep up more meteors than the sunset (as commonly named...) part of the Earth, where the local time is around 6pm. And if the Earth is a geoid, this variation should be sinusoidal – the distinctive smooth shape of a wave as traced out by points rotating around a circle. And this is exactly what professional astronomers observe (see [588]).

76. Gravity Probe B has confirmed the geodetic effect and frame-dragging effect given by General Relativity of Earth and the results are compatible with a geoid Earth but incompatible with a flat Earth. This was to be accomplished by measuring, very precisely, tiny changes in the direction of spin of four gyroscopes contained in an Earth-orbiting satellite at 650 [km] of altitude, crossing directly over the poles. Initial results confirmed the expected geodetic effect to an accuracy of about 0.5% and the frame-dragging effect had been confirmed to within 15% of the expected result. In an article published in the journal Physical Review Letters in 12011 (holocene calendar), the authors reported analysis of the data from all four gyroscopes results in a geodetic drift rate of $-6,601.8 \pm 18.3$ milliarcsecond per year and a frame-dragging drift rate of -37.2 ± 7.2 milliarcsecond per year, in good agreement with the General Relativity predictions of $-6,606.1 \pm 0.28\%$ milliarcsecond per year and $-39.2 \pm 0.19\%$ milliarcsecond per year, respectively (see [170]).

77. The "Blue hour" (night comes from the bottom and not from the top), the "Venus Belt" (pinkish glow that surrounds the observer when the Sun is near the horizon), the "Earth shadow" (the shadow that Earth itself casts through its atmosphere and into outer space toward the antisolar point), the "anticrepuscular rays" (phenomena similar to crepuscular rays that appear however from below the horizon) are all atmospheric phenomenon that have a well detailed description on a geoid Earth model where the Sun sets below the horizon but cannot be explained on a flat Earth model.

78. In the flat Earth model the atmosphere of the Earth is a half-spherical dome. If this was the case the pressure would be proportional to $P \propto \sqrt{R^2 - d^2}$ where d is the distance to the North pole and R is the radius of the flat Earth. Hence the atmospheric pressure near the equator would be half of that of the North pole and the atmospheric pressure at Antarctica would be negligible. However the highest sea-level air pressure ever recorded

was 1083.8 [mb] in Agata, Siberia on December 31, 11968 (holocene calendar); produced by a very cold, dense air mass. The lowest sea-level air pressure ever recorded was 870 [mb] measured on October 12, 11979 (holocene calendar) in the eye of Typhoon Tip near the Philippines as it moved over Guam (a difference of only approximately 15%...).

79. The U.S. Public Land Survey System (PLSS) was established shortly after the Revolutionary War as a way to describe and record parcels of land for legal purposes. In this system, land is divided into pieces named "townships" that are generally 6 miles on a side and containing 36 sections. Each section is about 1 mile square (1.6 kilometer square) and contains 640 acres (2.59 square kilometer). As the Earth is roughly spherical. When you try to cover the surface of a sphere with squares, they are not going to line up perfectly. That means, every so often, sections of the grid shift away from each other. That's why the roads that follow these boundaries must dogleg every twenty-four miles (38.6 kilometres) to counter the diminishing distances.

80. The dynamics of plate tectonics and the consequence of continents drift confirmed thanks to geological techniques cannot work on a flat Earth that has a boundary as some tectonic plates and continents have drifted over and beyond the actual Antarctica. Furthermore, the flat earthers' argument that Antarctica holds water on the flat Earth so it doesn't fall into space doesn't work since the Antarctica continent has only existed for about 80 million years.

81. Sadly many people still think that a scientist or engineer opinion is some kind of evidence. We can see quotes of engineers (...) on social networks (without source obviously) who state that the Earth isn't a globe. For information there are thousand of scientific paper where scientists state that the Earth is an oblate sphere/geoid. It would take hundred of pages to list them all. Let us give however just a few of them:

    - Aristotle (ancient Greek philosopher and polymath) in his book *On the Heavens* in Book II, part 14 (9700): « *Its shape must necessarily be spherical. For every portion of Earth has weight until it reaches the centre, and the jostling of parts greater and smaller would bring about not a waved surface, but rather compression and convergence of part and part until the center is reached* ».

    - Archimedes (ancient Greek mathematician, physicist, engineer, astronomer, and inventor who derived the law of buoyancy) in his book *On Floating Bodies*, Book I 2. 2. (9800): « *The surface of any fluid which is so located that it remains motionless will have the form of a sphere which has the same center as the Earth* ».

    - Strabo (geographer, philosopher, and historian) in his book *Geographica* in Part C, section 11, paragraph 20 (9993): « *...the world is also spherical, and the surface of the Earth is also spherical...* ».

    - Isaac Newton (polymath active as a mathematician, physicist, astronomer, alchemist, theologian, and author) in his book *Treatise of the System of the World* (published posthumously in 11728) clearly states multiples times that the Earth is a globe: « *Let $ABCD$ represent the globe of the Earth...* » (page 42); « *...let fall the perpendicular fG, meeting the globe of the Earth...* » (page 84).

    - Leonhard Euler (mathematician, physicist, astronomer, geographer, logician, and engineer) in his Article 32 *On the Shape of the Earth*, published in Anmerkungen über die Zeitungen, St. Petersburg (11738): « *After the absurd beliefs of the Ancients* *concerning the shape of the Earth had been sufficiently disproved, not only by the philosophers, but by actual travels, it appeared to be a settled matter that the Earth must be perfectly round like a ball* ».

- Joseph-Louis Lagrange (mathematician, physicist and astronomer) in his various papers mentions multiple times the fact that the Earth is a globe. Like in his Memory on the transit of Venus published at l'Académie des Sciences et Belles-Lettres de Berlin, t. XXII, page 8 (11766): « *Now, if by the pole P of the terrestrial globe and the place L whose latitude is...* ».
- Pierre-Simon, Marquis de Laplace (scholar whose work was important to the development of engineering, mathematics, statistics, physics, astronomy, and philosophy) in his famous 5 volumes Treatise in Celestial Mechanics published at l'imprimerie de Crapelet (11798 and 11799) mentions multiples time the globe and spherical shape of the Earth like for example at page 343 section 13: « *Let us now compare the preceding theory with the observations, and see the consequences which result from it on the constitution of the terrestrial globe* ».
- Siméon Denis Poisson (mathematician and physicist) in his quite famous *Treatise on the movement of the earth around its center of gravity* published at the Academie des Sciences at page 10 (11827): « *This can only take place as long as the axis of rotation deviates very little from one of the principal axes, which must be that of the greatest moment of inertia, because the Earth is a spheroid flattened on its poles* ».
- Jean-Baptiste Joseph Fourier (French mathematician and physicist) in his *On the Temperatures of the Terrestrial Sphere and Interplanetary Space* hich originally appeared in Mémoires de l'Acad;emie Royale des Sciences de l'Institut de France VII 570-604 (1827): « *The mathematical theory of heat furnishes several other consequences of this type, whose certainty is independent of all hypotheses regarding the state of the interior of the terrestrial globe* ».
- Albert Einstein (PhD Physicist, Professor, Nobel Prize in Physics), in his Chicago/USA conference (Chicago Lectures) at the Francis Parker School on May 6, 11921 (holocene calendar) on page 28 of his lecture notes refers to the spherical shape of the Earth: « *Wenn jemand um die Erde herumlaeuft, findet er nir- gends ein Ende, ebenso wie bei einer Kugel. Fuellen wir die Erde oder Kugel mit Staeben aus, dann kommen wir zu einem Ende, und wenn es wahr ist, dass es ueberall in der Welt Materie gibt, dann ist die Erde unbegrenzt aber endlich, und wir muessen das Ende erreichen* ».
- Auguste Piccard (PhD in Physics of ETHZ, Switzerland) in *Earth, size and sea* published at Oxford University Press, chapter 6, page 120 (11959): « *The geophysicists have installed a network of stations over the globe* ».
- Will Featherstone (PhD, Professor of Geodesy, Curtin University, Perth, Australia), *On the use of the geoid in geophysics: a case study over the North West Shelf of Australia* (11997) published in Exploration Geophysics, 28(2), 52-57: « *The geoid is the fundamental surface that defines the figure of the Earth* ».
- Edgar Dean Mitchell (PhD, Engineer in Aeronautics and Astronautics from the MIT) NASA astronaut and Lunar Module Pilot of Apollo 14 in 11971 (holocene calendar) and who spent nine hours working on the lunar surface in the Fra Mauro Highlands region, and was the sixth person to walk on the Moon: « *Suddenly, from behind the rim of the moon in long, slow motion movements of immense majesty,*

there emerges a sparkling blue and white jewel, a light, delicate sky blue sphere laced with slowly swirling veils of white rising gradually like a small pearl in a thick sea of black mystery. It takes more than a moment to fully realize this is the earth - home ».

- Hans Volland (PhD, Professor, Radioastronomical Institute, University of Bonn, Germany), *Atmosphere and Earth's rotation* (11996) published in Surveys in Geophysics, 17, 101-144: « *The rotating Earth as a gyroscoping geoid (approximately an oblate spheroid) is subject to external as well as internal torques. External torques are the tidal forces exerted by the Sun and Moon on the equatorial bulge of the Earth which cause the precession of the Earth's spin axis along a cone over* $25,700$ *years... The atmospheric boundary layer where friction mainly occurs consists of three regions (e.g., Stull, 11989; Peixoto and Oort, 11992). The first is a thin laminar surface layer above the ground, typically a few millimeters thick, where viscous effects dominate and relative motions between fluid and solid surface are prevented* ».
- Olena Kuzii and Andrij Rovenchak (Department for Theoretical Physics, Ivan Franko National University of Lviv, Ukraine), *What the gravitation of a flat Earth would look like and why thus the Earth is not actually flat* published in European Journal of Physics (12019), Volume 2, number 3: « *From the derived results, we are able to make some conclusions regarding a flat-Earth world and to demonstrate its contradictions with what is observed in reality* ».
- Thomas A. Herring (PhD in Earth and Planetary Sciences, Department of Earth, Atmospheric, and Planetary Sciences, Massachusetts Institute of Technology, Cambridge, Massachusetts), *The rotation of the earth* published in Reviews of Geophysics (11991), Volume 29, Issue S1, pages 172-175: « *Earth rotation studies from 1987-1990 have improved accuracy and temporal resolution, leading to a greater understanding of variations in the rotation of the Earth* ».
- Hermann Glauert (aerodynamicist and Principal Scientific Officer of the Royal Aircraft Establishment, Farnborough), *Rotation of the Earth*, Monthly Notices of the Royal Astronomical Society, Vol. 75, p.685 (11915): « *The rotation of the Earth is crucial for regulating day and night, seasons, tides, and measuring time, but its uniformity has been disturbed by precession, nutation, and pole shifts* ».
- American Congress on Surveying and Mapping in its manual *Definitions of Surveying and Associated Terms* (12015), 314 pages we can read: « *Curvature of the Earth, correction for [SURVEYING]- That offset from the tangent to the curve resulting from curvature of the Earth. The offset amounts to about* 8 *cm at* 1 *km distance. That offset which is given in surveying tables as correction for curvature of the Earth. The values given in such tables usually combine the effects of both curvature the Earth and atmospheric refraction. Under normal conditions, the atmospheric refraction compensates partially for the curvature of the Earth, so the correction is about* 6 *cm for a point* 1 *km away* ».
- Raymond Hide (PhD in Physics, visiting professor in the Department of Physics at the University of Oxford) and Jean Dickey (PhD in High-Energy Physics, president of the American Geophysical Union), in *Earth's Variable Rotation* published in Science, volume 253, number 5020, pages 629-637 (11991): « *Earth's rotation fluctuations impact core-mantle boundary topography, interior processes, and atmospheric variations, with implications for oceans and climate* ».

- He Xianqiang (PhD Physical Electronics from the Shanghai Institute of Technical Physics), Knut Stamnes (PhD in Physics and professor of physics at Stevens Institute of Technology), Yan Bai (Second Institute of Oceanography,) in *Effects of Earth curvature on atmospheric correction for ocean color remote sensing* published in Remote Sensing of Environment (Elsevier) Volume 209, pages 118-133 (2018): « *Earth curvature significantly impacts ocean color remote sensing, and considering it in atmospheric correction is crucial for high accuracy* ».
- Bowie William (Honorary Degrees from the University of Edinburgh, Scotland, at the meeting of the International Union of Geodesy and Geophysics) in *Isostasy and the Size and Shape of the Earth* published in Science, volume 39, number 1011, page 697-701 (11914): « *The announcement by Newton in 1687 of his theory that the Earth was an oblate spheroid added much interest to the subject of its exact shape. A meridional are of about* $8^1/_2$ *degrees, extending north and south of Paris, was measured by J. and D. Cassini between the years 1683 and 1716. The results of the first computations of this are indicated that the length of the degree was less at the northern than at the southern end. This gave to the Earth the shape of a prolate spheroid. A great controversy arose over the question as to whether the Earth has the form of an oblate or prolate spheroid, and to settle it the French Academy sent expeditions to Peru in 1735 and to Lapland the following year to measure ares near the equator and within the arctic circle. The result of these measurements confirmed the theory of the oblate spheroid* ».
- Gates, W. Lawrence (PhD in Meteorology from the Massachusetts Institute of Technology) in *Derivation of the Equations of Atmospheric Motion in Oblate Spheroidal Coordinates* published in the Journal of the atmospheric sciences, volume 61, number 20, pages 2478-2487 (12004): « *Earth is more nearly an oblate spheroid than a sphere, making it of theoretical interest to develop atmospheric equations of motion in spheroidal coordinates* ».
- Niklas Axel Mörner af Morlanda (PhD in Quaternary Geology, swedish geologist and geophysicist, head of the paleogeophysics and geodynamics unit at Stockholm University) in *Geoidal topography: Origin and time consistency* published at Springer Geodetic Features of the Ocean Surface and their Implications, pages 205-208 (11984): « *The geoid topography, as a direct measure of the irregular density distribution within the Earth, provides evidence of density changes within the Earth over time, indicating a high-dynamic Earth* ».
- Martine Amalvict (Associate Professor, Institute of Physics of the Globe, Louis Pasteur University) and al. in *The geoid: From geodesy to geophysics and from geophysics to geodesy* published in Surveys in Geophysics, Volume 14, pages 447-494 (11993): « *The geoid is a mathematical and observational concept that studies the inner structure and dynamcis of the Earth through its shape and anomalies* ».
- William Edward Featherstone (PhD, Professor of Geodesy, Curtin University, Perth, Australia) in *On the use of the geoid in geophysics: a case study over the North West Shelf of Australia* published in Exploration Geophysics, volume 28, number 2, pages 52-27 (11997): « *The geoid is the fundamental surface that defines the figure of the Earth. It is approximated by mean sea-level and undulates due to spatial variations in the Earth's gravity field* ».
- + many other thousands of scientific paper quotes...

82. And now also some quotes of people that are not scientists and who confirm Earth isn't flat:

    - Alexeï Leonov (Graduate from the Chuguev Higher Air Force Pilots School) was a Soviet and Russian cosmonaut, Air Force major general that the 18 March 11965 (holocene calendar) became the first person to conduct a spacewalk, exiting the capsule during the Voskhod 2 mission for 12 minutes and 9 seconds: « *The Earth was small, light blue, and so touchingly alone, our home that must be defended like a holy relic. The Earth was absolutely round. I believe I never knew what the world round meant until I saw Earth from Space* ».
    - Sheikh Muszaphar Shukor Al Masrie bin Sheikh Mustapha (Dr in Orthopaedic Surgery) was a spaceflight participant into the International Space Station aboard Soyuz TMA-11 with the Expedition 16 crew on 10 October 12007 (holocene calendar) for a ten days program in space. He shared on Instagram on his personal account the 11 october 12019 (holocene calendar) a private Instagram discussion where he wrote to another muslim: « *In the name of Allah I swear the Earth is Sphere as seen with my own eyes from Space* ». Sheikh Muszaphar also wrote in the description of post: « *I don't simply use the name of God just to prove a point and make people believe me, but if this is what it takes... then I swear in the name of God that the Earth is a sphere as seen with my own eyes from space* ».
    - Felix Baumgartner (Austrian skydiver, daredevil and Base jumper) world record owner for skydiving at an estimated of 39 km the 14 October 12012: « *When you're standing there in a pressure suit, the only thing that you hear is yourself breathing, and you can see the curvature of the Earth; you can see the sky's totally black* ».
    - Colonel Buz Carpenter graduated from the USAF Academy), SR-71 (blackbird) pilot in the US Air Force in an interview video by Lockheed Martin in 2013 : « *I wish I could take everybody up to* $85,000$ *feet because you can see 350 miles in a direction. You see the curvature of the Earth* ».
    - John Beckman (PhD in Theoretical Physics and Astrophysics at the University of Oxford) flight in the Concorde 001 during the Solar eclipse of July 10, 11993 (holocene calendar): « *Everyone was very focused on their work, but I still had time to look out a side window to see the shadow, the half-light and the light that was barely breaking through behind. From our altitude, I could even see the curvature of the Earth, it was incredible. I could also observe the solar corona, and as the moon gradually occulted the solar disk, I saw the chromosphere, which was emitting flashes of red light* ».
    - *Global Navigation for Pilots - International Flight Techniques and Procedures*, 3rd Edition (441 pages) by PhD Dale de Remer and Gary M. Ullrich published (12019) at Aviation Supplies & Academics Newcastle, Washington (USA): « *This difference expresses the ellipticity of the Earth. Sometimes, this is expressed as a ratio of the difference between polar and equatorial diameters to the equatorial diameter* ».
    - Anderle, Richard J. (Computation and Analysis Laboratory, US Naval Surface Weapons Center) in *Determination of the Earth's Geoid by satellite observations* NWL Report No. 2027 (11966): « *Satellite observations can determine the Earth's geoid to about 20 meters accuracy, but further data and computation techniques can improve this to 10 meters or better* ».

- Zhiping Lu et Al. (Department of Geodesy, Information Engineering University Institute of Surveying and Mapping, Zhengzhou, China) in *The Geoid and Different Hight Systems* in Introduction to Geodetic Datum and Geodetic Systems, published in Springer (12014): « *The shape of the Earth studied in geodesy primarily refers to the shape of the geoid, which is the physical shape of the Earth and serves as a reference surface for height determination* ».
- + many other hundreds of engineers, pilots, adventurers quotes...

Remark

Remember that it's obviously for pedagogical reasons that children learn first that Earth is idealized as a perfect sphere, after when teenagers most will study the evidence that it's not a perfect sphere but an oblate-spheroid and later when young adult they will learn the concept of geoid and the relative evidence about Earth being a geoid. Popular science communicators or popular science journals for adults sometimes make the same pedagogical choice.

So finally empirical, reproducible, testable experiences and measurements provide evidence that the Earth is an oblate spheroid and is not shaped like an ostrich egg (like Islam claim and describe it) or like a snake egg (like Hinduism claim and describe it) or flat (like Judaism and Christianism claim and describe it) whose Sun revolves around (geocentrism). For a modern visualisation see `https://icgem.gfz-potsdam.de/vis3d/longtime` for more details see **??**.

12.1.4.9 Stability of Atmospheres

Comparing the liberation velocity and the velocities of various gases, we can explain the stability of certain atmospheres and the absence of others. We have proved in the section of Classical Mechanics (see page 3234) that the liberation velocity of a spherical star was given by the following relation (on which we will come back in the section of General Relativity at page 5720):

$$v_L=\sqrt{\frac{2GM}{R}} \tag{12.1.301}$$

For the Earth, a numerical application gives $v_L=11.2\cdot 10^3\,[\mathrm{m}\cdot\mathrm{s}^{-1}]$ and for the Moon $v_L=2.37\cdot 10^3\,[\mathrm{m}\cdot\mathrm{s}^{-1}]$.

Let us recall that we have proved in the section of Continuum Mechanics during our study of the kinetic temperature (see page 3897) the following relation (virial theorem):

$$v=\sqrt{\frac{3kT}{m}} \tag{12.1.302}$$

Using the molar mass (see section Thermochemistry page 6252):

$$v=\sqrt{\frac{3kT}{M_m/N_\mathrm{A}}} \tag{12.1.303}$$

A numerical application gives for nitrogen $v_{\text{Az}} = 517\,[\text{m}\cdot\text{s}^{-1}]$ and for hydrogen $v_{\text{H}} = 1,934\,[\text{m}\cdot\text{s}^{-1}]$ with an arbitrary temperature of $300\,[\text{K}]$.

So nitrogen is obviously trapped in the Earth's atmosphere. Hydrogen, light gas, more fast is less trapped. The two gases are even less trapped by the Moon.

As provided in the paper [25], a planet waterworld like body should have approximately 0.0268 (i.e. $\sim 1.6\cdot 10^{23}$ [kg]) the mass of the Earth to be sustainable for life (including climate, atmosphere stability, gravity conditions, distance to main star):

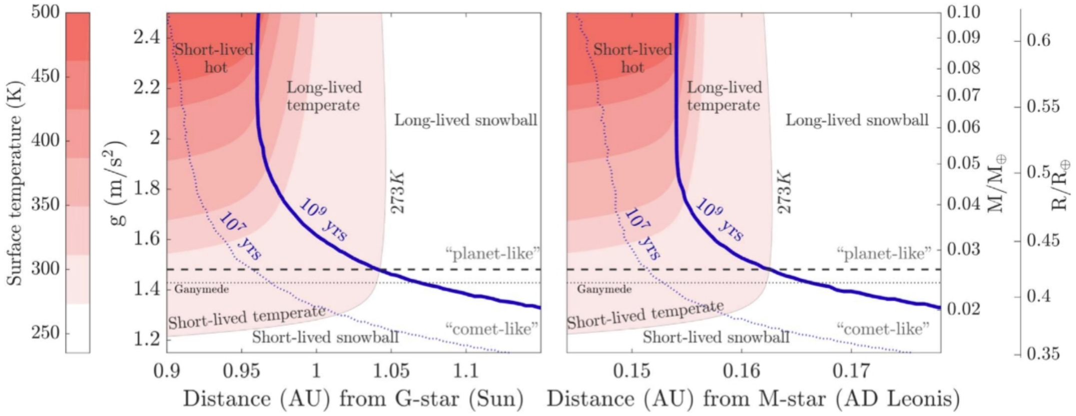

Figure 12.51: Steady-state surface temperatures and water lifetimes obtained by numerical computations

Remark

In fact, the mean square speed is not the only speed of molecules. There is a distribution of velocities. We have indeed study the Maxwell-Boltzmann distribution of a gas at equilibrium in the section of Statistical Mechanics (see page 3561).

The below image of Earth's atmosphere merging with the emptiness of space resembles an abstract painting. It was taken over western China in June 12007 (holocene calendar) by a Space Shuttle crew member. The thin silvery streaks (named "noctilucent clouds") high in the blue area are at a height of about 80 kilometres. The atmosphere at this altitude is very thin. Air pressure here is less than a thousandth of that at sea level. The thin reddish zone in the lower portion of the image is the densest part of the atmosphere. It is here, in a layer named the "troposphere", that practically all weather and cloud formation occur. Ninety percent of Earth's atmosphere occurs within just 16 kilometres of the surface.

Figure 12.53: **The eight "layers" (...) of the atmosphere**
(source: `https://www.sciencefacts.net/layers-of-atmosphere.html`**, authors: Satyam Bhuyan, Santanu Mukherjee)**

Remark

In 12019 (holocene calendar), scientists discovered that Earth's atmosphere consists of a hydrogen cloud named the "geocorona" that extends to the Moon and beyond. Its density is tiny and practically vacuum. It does not affect space travel. The geocorona extends almost twice the distance to the Moon. Only 0.2 hydrogen atoms per $[\text{cm}^3]$ at the Moon's distance and 70 hydrogen atoms per $[\text{cm}^3]$ at $60,000$ kilometers above Earth's surface.

We can see by the way that if we put $v_L = v$, and seek for M for a given temperature T and radius R we get after a simple algebraic simplification:

$$M_{\text{min}} = \frac{3kTRN_A}{2GM_m} \tag{12.1.304}$$

A numerical application at $T = 293$ [K] for typical air molar mass $2.9 \cdot 10^{-2}$ $[\text{kg} \cdot \text{mole}^{-1}]$ and a ball of radius equal to 1 [m] gives:

$$M_{\text{min}}=\frac{3kTRN_A}{2GM_m}\cong\frac{3\cdot(1.38\cdot 10^{-23})\cdot 293\cdot 1\cdot(6.02\cdot 10^{23})}{2\cdot(6.67\cdot 10^{-11})\cdot(2.9\cdot 10^{-2})}\cong 1.89\cdot 10^{15}\;[\text{kg}] \tag{12.1.305}$$

So it's quite unrealistic to reproduce such a phenomena in a laboratory for now... Indeed, remember for example that our Moon's mass is actually around $7.349\cdot 10^{22}$ [kg] and Earth's mass is actually around $5.9722\cdot 10^{24}$ [kg]. And the biggest human structure existing actually build by humans at the day we write these lines is an Chinese Dam that weights only something in the order of 10^9 [kg]...

12.1.4.10 Planetary equilibrium temperature

Let us consider a planet orbiting its host star. The star emits radiation isotropically, and some fraction of its emittance reaches the planet. The amount of radiation arriving at the planet is referred to as the incident star radiation, M_{star}. The planet has an albedo that depends on the characteristics of its surface and atmosphere, and therefore only absorbs a fraction of the emittance. The planet absorbs the emittance that isn't reflected by the albedo, and heats up. One may assume that the planet radiates energy like a black-body at some temperature according to the Stefan–Boltzmann law. Thermal equilibrium exists when the power supplied by the star is equal to the power emitted by the planet. The temperature at which this balance occurs is the "planetary equilibrium temperature".

The solar flux (i.e. emittance) absorbed (abs) by the planet from the star is equal to the flux emitted (emit) by the planet:

$$M_{\text{abs}}=M_{\text{emit}} \tag{12.1.306}$$

Assuming a fraction of the incident starlight is reflected according to the planet's albedo ρ:

$$(1-\rho)\bar{M}_{\text{star}}=M_{\text{emit}} \tag{12.1.307}$$

where $\bar{M}_{\text{star}}$ represents the area- and time-averaged incident star flux, and may be expressed as:

$$\bar{M}_{\text{star}}=\frac{M_{\text{star}}}{4} \tag{12.1.308}$$

The factor of $1/4$ in the above formula comes from the fact that only a single hemisphere is lit at any moment in time (creates a factor of $1/2$), and from integrating over angles of incident sunlight on the lit hemisphere (creating another obvious factor of $1/2$).

Assuming the planet radiates as a black-body according to the Stefan–Boltzmann law (see section Mechanics page 3706):

$$M(T)=\frac{2\pi^5k^4}{15c^2h^3}T^4=\sigma T^4 \tag{12.1.309}$$

at some equilibrium temperature T_{eq}, a balance of the absorbed and outgoing fluxes produces:

$$(1-\rho)\frac{M_{\text{star}}}{4}=\sigma T_{\text{eq}}^4 \tag{12.1.310}$$

Rearranging the above equation to find the equilibrium temperature leads to:

$$T_{\text{eq}}=\sqrt[4]{\frac{M_{\text{star}}(1-\rho)}{4\sigma}} \tag{12.1.311}$$

Obviously we see that this relation doesn't depends on the distance to the star. So the idea is to rewrite this relation using the temperature at the surface of the star first (using Stefan-Boltzmann law again), to multiply by its surface, and divide it directly afterwards by the surface of the sphere going from the center of the star to the position of the planet at a distance r.

Therefore (we introduce the bolometric[13] intrinsic luminosity L that has for units [W]):

$$T_{\text{eq}}=\sqrt[4]{\frac{\dfrac{4\pi R_{\text{star}}^2\sigma T_{\text{star}}^4}{4\pi r^2}(1-\rho)}{4\sigma}}=\sqrt[4]{\frac{\dfrac{L_{\text{star}}}{4\pi r^2}(1-\rho)}{4\sigma}}=\sqrt[4]{\frac{L_{\text{star}}(1-\rho)}{16\pi r^2\sigma}} \tag{12.1.312}$$

The relation:

$$\boxed{T_{\text{eq}}=\sqrt[4]{\frac{L_{\text{star}}(1-\rho)}{16\pi r^2\sigma_{\text{S.B.}}}}} \tag{12.1.313}$$

is named the "planetary equilibrium temperature".

The equilibrium temperature is neither an upper nor lower bound on actual temperatures on a planet. There are several reasons why measured temperatures deviate from predicted equilibrium temperatures (non-circular orbit, planet precession, etc.).

---

[13] A measure is said to be "bolometric" if it measure the total amount of energy across the full electromagnetic spectrum!

12.1.5 Roche's Limit

The Roche limit is the theoretical distance below which a satellite would begin to break down under the action of tidal forces caused by the celestial body around which it orbit, these forces exceeding the satellite internal cohesion.

We can simplify the problem by considering the satellite liquid, not rotating on itself (no spin), and decomposing it into two small masses m of radius r and volumetric density ρ_S.

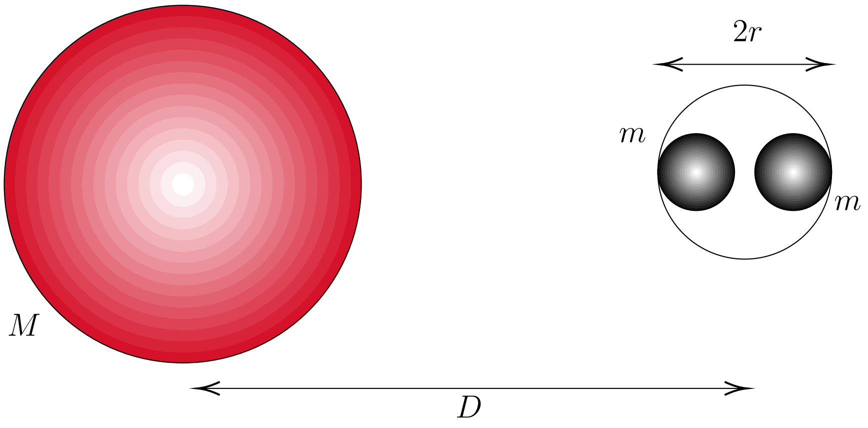

Figure 12.54: **Configuration for the study of the Roche limit**

The planet is a sphere of radius R, mass M, volume density ρ_P, located at a distance D of the satellite axis.

The planet exerts on the satellite the gravitational attraction:

$$F_a = G\frac{mM}{D^2} \tag{12.1.314}$$

The difference of forces between the two masses is:

$$\Delta F_a = G\frac{mM}{(D-r)^2} - G\frac{mM}{(D+r)^2} \tag{12.1.315}$$

We can consider that $r \ll D$, giving:

$$\frac{1}{(D-r)^2} - \frac{1}{(D+r)^2} \cong \frac{1}{D^2}\left(\frac{1}{1-2\dfrac{r}{D}} - \frac{1}{1+2\dfrac{r}{D}}\right) = \frac{1}{D^2}\frac{4\dfrac{r}{D}}{\left(1-2\dfrac{r}{D}\right)\left(1+2\dfrac{r}{D}\right)} \cong 4\frac{r}{D^3} \tag{12.1.316}$$

So the difference in force is

$$\Delta F_a = G\frac{4mM}{D^3}r \tag{12.1.317}$$

If the satellite cohesive force result in the gravitational attraction between the two masses:

$$F_c = G\frac{m^2}{(2r)^2} \tag{12.1.318}$$

The satellite is destroyed if the difference in strength between the two masses is greater than the cohesive force:

$$G\frac{m^2}{4r^2} \geq G\frac{4mM}{D^3}r \tag{12.1.319}$$

But we have the relations:

$$M = \frac{4}{3}\pi R^3 \rho_P \quad \text{and} \quad m = \frac{4}{3}\pi r^3 \rho_S \tag{12.1.320}$$

Therefore we get:

$$\frac{\rho_S}{\rho_P} \leq 16\frac{R^3}{D^3} \tag{12.1.321}$$

and we deduce of it the "Roche limit":

$$\boxed{D_{\text{Roche}} \lesssim 2.5R\sqrt[3]{\frac{\rho_P}{\rho_S}}} \tag{12.1.322}$$

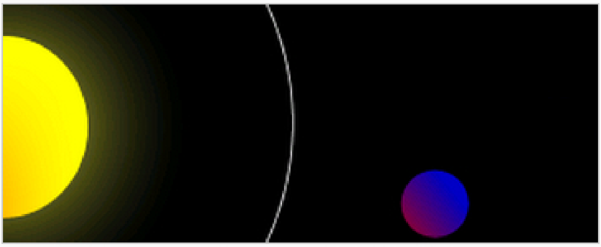
Depending on the approach and the approximations there can be a factor 3 between some results.

Remark

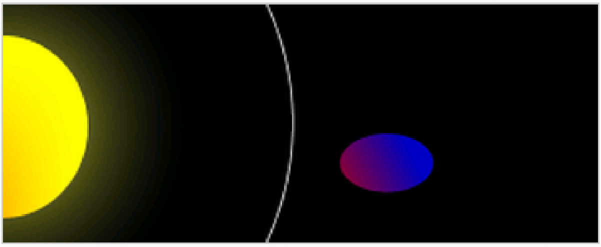
For example the calculations given on Wikipedia consider only the difference in the primary's gravitational pull on the center of the satellite and on the edge of the satellite closest to the primary. This means that the main mass only apply one force momentum. But in fact this is not accurate as what interest us is the difference between the two extremities. This is why there is a factor 2 between the Wikipedia calculations and ours (with our result the satellite will break twice the distance of that given by Wikipedia).

Since in this calculation, we considered a satellite as a two point masses without rotation, and again we have assumed that the satellite's cohesion was provided exclusively by gravitational interactions, this value is just an order of magnitude for rigid body where material is only aggregated by gravity (and not molecular forces).

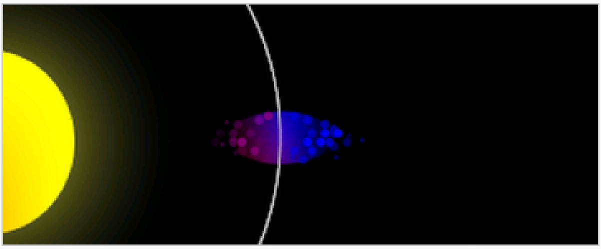
The Roche limit is one (but not the only one!) source of rings around planets as depicted by the illustration below:



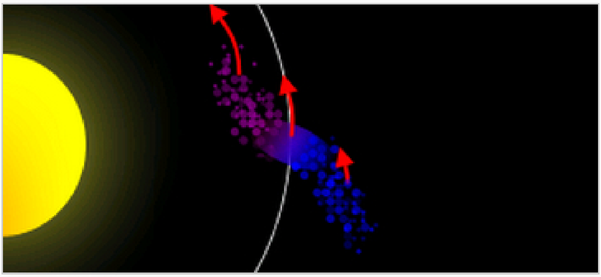
Consider an orbiting mass of fluid held together by gravity, here viewed from above the orbital plane. Far from the Roche limit the mass is practically spherical.



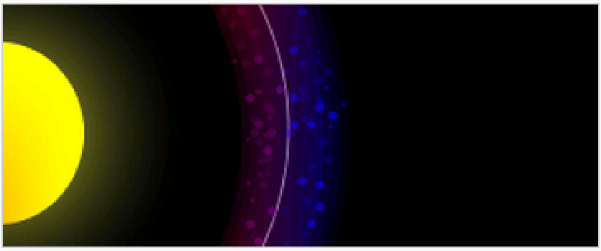
Closer to the Roche limit the body is deformed by tidal forces.



Within the Roche limit the mass's own gravity can no longer withstand the tidal forces, and the body disintegrates.



Particles closer to the primary move more quickly than particles farther away, as represented by the red arrows.



The varying orbital speed of the material eventually causes it to form a ring.

Figure 12.55: **Roche limit as one of the sources of planetary rings**

12.1.6 Keplerian Orbitals

Observation (main tool of the physicist and engineer for recall...) suggests at first glance, that the trajectories of celestial bodies in orbit around stars are indeed conical type (whew!) in the heliocentric reference frame. Knowing this, we can, in order to facilitate the calculation, anticipate the complexity of calculations and express the dynamics directly from a material point in polar coordinates.

As we saw it in the section Vector Calculus (see page 1863), the speed in polar coordinate is expressed by the relation (we changed the angle Greek letter notation to adapt it to the tradition in astronomy):

$$\vec{v}=\frac{\mathrm{d}r}{\mathrm{d}t}\vec{u}_r+r\frac{\mathrm{d}\theta}{\mathrm{d}t}\vec{u}_\theta \tag{12.1.323}$$

where to recall the first term is the radial velocity component and the second component the tangential (angular) velocity!

For acceleration (the proof is also in the section of Vector Calculus at the same page):

$$\vec{a}=\left(\frac{\mathrm{d}^2r}{\mathrm{d}t^2}-r\left(\frac{\mathrm{d}\theta}{\mathrm{d}t}\right)^2\right)\vec{u}_r+\left(2\frac{\mathrm{d}r}{\mathrm{d}t}\frac{\mathrm{d}\theta}{\mathrm{d}t}+r\frac{\mathrm{d}^2\theta}{\mathrm{d}t^2}\right)\vec{u}_\theta \tag{12.1.324}$$

Now that we have the tools, let us get to the case of Keplerian orbits in the case of a static Newtonian field.

There are to our knowledge two main ways of doing the necessary mathematical developments but that do not give (to our knowledge) the same level of detailed results. The first approach provides finer results but is sometimes a bit do-it-yourself sometimes... is based on the use of the radial velocity and an important relation in astronomy, named the "first Binet formula". The second approach is simpler and more elegant, it uses the radial acceleration to approach the problem and we get a special relation named the "second Binet formula".

12.1.6.1 First Binet Formula (radial velocity)

To start with this first approach to the problem, remember that we have already proved earlier that:

$$\vec{F}=G\frac{Mm}{r^2}\vec{u}=-\overrightarrow{\text{grad}}\left(G\frac{Mm}{r}\right)=-\overrightarrow{\text{grad}}(U)=-m\vec{\nabla}\cdot U \tag{12.1.325}$$

However, it is unlikely that the main body is a perfect and homogeneous sphere ... so Astrophysicists have the habit of noting Newtonian potential U under the form:

$$U=-\frac{\mu}{r}(f) \tag{12.1.326}$$

where $\mu=GM$ is named "gravitational constant of the star" (even if it is not always a star...) and where f is a function representing the heterogeneity of the star.

If there is one place in the universe where the laws of mechanics are perfectly verifiable, it is space, because the friction or causes of dissipation are extremely small. Within the field of a single force deriving from a potential, the movement satisfies the conservation of mechanical energy.

Thus we end in the so-named "energy equation", wherein E denotes the "specific energy" per unit weight (kilogram):

$$E_{\text{tot}}=E_{\text{c}}+U=\frac{1}{2}mv^2-m\frac{\mu}{r}=m\left(\frac{1}{2}v^2-\frac{\mu}{r}\right)=mE \tag{12.1.327}$$

Therefore:

$$\boxed{E=\frac{1}{2}v^2-\frac{\mu}{r}} \tag{12.1.328}$$

The Newtonian gravitational force is central, thus having a null torque force at the center O of the main body. This results in the conservation of angular momentum in norm and direction, either:

$$\vec{b}=\vec{r}\times m\vec{v}=m\vec{h}\Rightarrow\vec{h}=\vec{r}\times\vec{v}=K\vec{W} \tag{12.1.329}$$

The vector $\vec{W}$ is the normalized vector of $\vec{b}$ or of $\vec{h}$ named the "reduced momentum". K is the constant of areas (see page 5234) such that:

$$K=\|\vec{h}\|=\|\vec{r}\times\vec{v}\| \tag{12.1.330}$$

We recall to the reader that the norm of the speed expressed in polar coordinates is given by the relation (remember that the both vectors of the polar base are orthogonal and that we can therefore apply the Pythagorean theorem to calculate the norm as it has been proved in the section of Vector Calculus):

$$v^2=\left(\frac{\mathrm{d}r}{\mathrm{d}t}\right)^2+r^2\left(\frac{\mathrm{d}\theta}{\mathrm{d}t}\right)^2 \tag{12.1.331}$$

Which gives us the possibility to write the area constant K as:

$$K=\|\vec{h}\|=\|\vec{r}\times\vec{v}\|=\left\|\vec{r}\times\left(\frac{\mathrm{d}r}{\mathrm{d}t}\vec{u}_r+r\frac{\mathrm{d}\theta}{\mathrm{d}t}\vec{u}_\theta\right)\right\|=r^2\frac{\mathrm{d}\theta}{\mathrm{d}t} \tag{12.1.332}$$

Let us now put ourselves in the orbital plane, in polar coordinates.

Given the relation already proved and known:

$$\vec{v}=\frac{\mathrm{d}r}{\mathrm{d}t}\vec{u}_r+r\frac{\mathrm{d}\theta}{\mathrm{d}t}\vec{u}_\theta \tag{12.1.333}$$

and its squared norm:

$$v^2=\left(\frac{\mathrm{d}r}{\mathrm{d}t}\right)^2+r^2\left(\frac{\mathrm{d}\theta}{\mathrm{d}t}\right)^2 \tag{12.1.334}$$

Or in the case of a central force (conservation of angular momentum):

$$r^2\frac{\mathrm{d}\theta}{\mathrm{d}t}=K\Leftrightarrow\frac{\mathrm{d}\theta}{\mathrm{d}t}=\frac{K}{r^2} \tag{12.1.335}$$

Let's put this in the prior-previous expression of v^2, then we have: Let us put this in the expression prior-previous expression of v^2, then we have:

$$\begin{aligned}v^2&=\left(\frac{\mathrm{d}r}{\mathrm{d}t}\right)^2+r^2\left(\frac{\mathrm{d}\theta}{\mathrm{d}t}\right)^2=v^2=\left(\frac{\mathrm{d}r}{\mathrm{d}t}\frac{\mathrm{d}\theta}{\mathrm{d}\theta}\right)^2+r^2\left(\frac{K}{r^2}\right)^2=\left(\frac{\mathrm{d}\theta}{\mathrm{d}t}\frac{\mathrm{d}r}{\mathrm{d}\theta}\right)^2+\frac{K^2}{r^2}\\&=\left(\frac{K}{r^2}\frac{\mathrm{d}r}{\mathrm{d}\theta}\right)^2+\frac{K^2}{r^2}=\left(-K\frac{\mathrm{d}}{\mathrm{d}\theta}\left(\frac{1}{r}\right)\right)^2+\frac{K^2}{r^2}=K^2\left(\left(\frac{\mathrm{d}}{\mathrm{d}\theta}\left(\frac{1}{r}\right)\right)^2+\frac{1}{r^2}\right)\end{aligned} \tag{12.1.336}$$

The relation:

$$\boxed{v^2=K^2\left(\left(\frac{\mathrm{d}}{\mathrm{d}\theta}\left(\frac{1}{r}\right)\right)^2+\frac{1}{r^2}\right)} \tag{12.1.337}$$

is named "Binet's first formula".

By equating with the expression of v^2 resulting from the conservation of energy that we get earlier above, we have:

$$K^2\left(\left(\frac{\mathrm{d}}{\mathrm{d}\theta}\left(\frac{1}{r}\right)\right)^2+\frac{1}{r^2}\right)=\frac{2\mu}{r}+2E \tag{12.1.338}$$

This gives us a rather complicated differential equation:

$$\left(\frac{\mathrm{d}}{\mathrm{d}\theta}\left(\frac{1}{r}\right)\right)^2=-\left(\frac{1}{r}-\frac{\mu}{K^2}\right)^2+\frac{\mu^2}{K^4}+\frac{2E}{K^2} \tag{12.1.339}$$

And then we wonder how we can get out of such a situation? After some hours of reflection ... we realize that takes to make a substitution. After another hour of neural chaos this ultimately leads to an end.... We decide to put (we have the right to do it!), knowing that r is a function of u and θ:

$$\frac{1}{r}-\frac{\mu}{K^2}=\sqrt{\frac{\mu^2}{K^4}+\frac{2E}{K^2}}u \tag{12.1.340}$$

Let us derivate merrily relatively to θ:

$$\frac{\mathrm{d}\left(\dfrac{1}{r}\right)}{\mathrm{d}\theta}=\sqrt{\frac{\mu^2}{K^4}+\frac{2E}{K^2}}\frac{\mathrm{d}u}{\mathrm{d}\theta} \tag{12.1.341}$$

Substituting in the differential equation:

$$\left(\sqrt{\frac{\mu^2}{K^4}+\frac{2E}{K^2}}\right)\left(\frac{\mathrm{d}u}{\mathrm{d}\theta}\right)^2=-\left(\sqrt{\frac{\mu^2}{K^4}+\frac{2E}{K^2}}\right)u^2+\left(\sqrt{\frac{\mu^2}{K^4}+\frac{2E}{K^2}}\right) \tag{12.1.342}$$

After simplification we get:

$$\frac{\mathrm{d}u}{\mathrm{d}\theta}=\pm\sqrt{1-u^2} \tag{12.1.343}$$

We separate the variables to integrate:

$$\int\pm\frac{\mathrm{d}u}{\sqrt{1-u^2}}=\int\mathrm{d}\theta \tag{12.1.344}$$

We have two solutions according to the sign we choose. However, at the end of the resolution, we notice that the only physically interesting choice is the negative sign. We have proved in the section of Differential and Integral Calculus during our study of common derivatives (see page 1475) that:

$$\begin{aligned}+\frac{\mathrm{d}\arccos(x)}{\mathrm{d}x}&=-\frac{1}{\sqrt{1-x^2}}\\-\frac{\mathrm{d}\arcsin(x)}{\mathrm{d}x}&=-\frac{1}{\sqrt{1-x^2}}\end{aligned} \tag{12.1.345}$$

We will chose the primitive in cosine and therefore we have:

$$\arccos(u)=\theta-\theta_0\Rightarrow u=\cos(\theta-\theta_0) \tag{12.1.346}$$

We leave, by approximation, the constant of integration that would involve very small oscillations in the orbit's path (if you do a study or a homework on this topic, you can transfer me your plots with or without the constant, it would interest me as I don't have time to do it myself).

This allows us to get:

$$\frac{1}{r}=\frac{\mu}{K^2}+\sqrt{\frac{\mu^2}{K^4}+\frac{2E}{K^2}}\cos(\theta-\theta_0) \tag{12.1.347}$$

Now we see that our choice of the sign for the integration is fully justified because now, if we do a little recall on conics (see section Analytical Geometry page 2764), we see that after rearrangement:

$$\begin{aligned}r&=\frac{1}{\dfrac{\mu}{K^2}+\sqrt{\dfrac{\mu^2}{K^4}+\dfrac{2E}{K^2}}\cos(\theta-\theta_0)}=\frac{\dfrac{K^2}{\mu}}{1+\dfrac{K^2}{\mu}\sqrt{\dfrac{\mu^2}{K^4}+\dfrac{2E}{K^2}}\cos(\theta-\theta_0)}\\&=\frac{\dfrac{K^2}{\mu}}{1+\sqrt{1+\dfrac{2EK^2}{\mu^2}}\cos(\theta-\theta_0)}\end{aligned} \tag{12.1.348}$$

So finally we have a relation of the following form if we choose $\theta_0=0$:

$$\boxed{r=\frac{p}{1+e\cos(\theta)}} \tag{12.1.349}$$

where by analogy with the section of Analytical Geometry e is the eccentricity (let us recall that $e=c/a<1$ with a the semi big axes and c the distance to the center of the ellipse to the focal) and p the focal parameter ($p=b^2/a$) of an ellipse. This corresponds well to the trajectories that follow celestial bodies in orbit.

We thus fall back on our the first Kepler "law"... so as we can see it, it can be proven!

In our case, we have after simplification to resume:

$$\boxed{p=\frac{b^2}{a}=\frac{K^2}{\mu} \quad \text{and} \quad e=\frac{b^2}{ah}=\sqrt{1+\frac{2EK^2}{\mu^2}}} \tag{12.1.350}$$

where (for recall) K is the areas constant :

$$K=\|\vec{h}\|=\|\vec{r}\times\vec{v}\| \tag{12.1.351}$$

and μ is the gravitation constant of the celestial body:

$$\mu=GM \tag{12.1.352}$$

and finally E the specific energy:

$$E=\frac{1}{2}v^2-\frac{\mu}{r} \tag{12.1.353}$$

The reader could be able to check himself as we have seen in the section of Analytical Geometry in our study conical that if:

- If $E=0$ such that $e=1$ we have an opened orbit in the form of a parabola
- If $E>0$ such that $e>1$ we have an opened orbit in the form of a hyperbola
- If $E\leq 0$ such that $0\geq e<1$ we have a closed orbit in the form of an ellipse or a circle

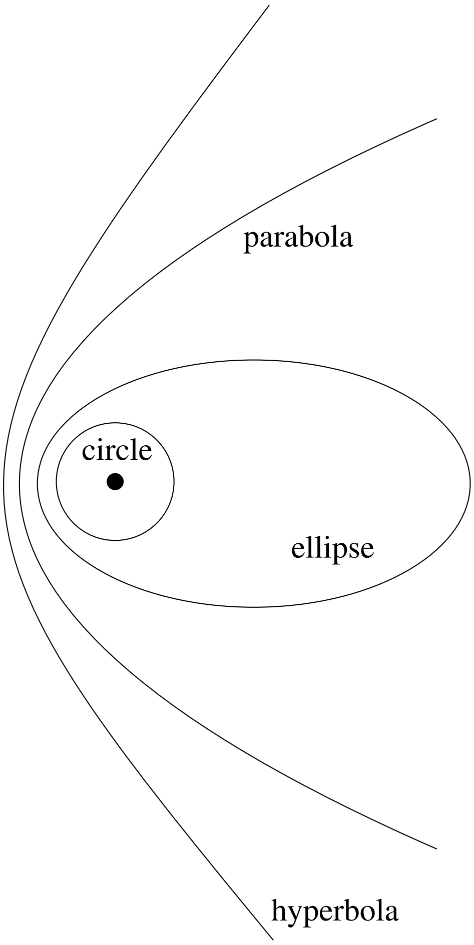


Figure 12.56: Reminders of conical but "orbit" oriented

Finally, if we inject:

$$r=\frac{p}{1+e\cos(\theta)} \tag{12.1.354}$$

in the first Binet formula:

$$v^2=K^2\left(\frac{\mathrm{d}}{\mathrm{d}\theta}\left(\frac{1}{r}\right)^2+\frac{1}{r^2}\right) \tag{12.1.355}$$

then we get the velocity in any point of the ellipse based on the primary variable parameter which is therefore the angle:

$$v^2=||\vec{r}\times\vec{v}||^2\left(\frac{\mathrm{d}}{\mathrm{d}\theta}\left(\frac{1+e\cos(\theta)}{p}\right)^2+\frac{p^2}{(1+e\cos(\theta))^2}\right) \tag{12.1.356}$$

Hence:

$$\boxed{v=||\vec{r}\times\vec{v}||\sqrt{\frac{-2(1+e\cos(\theta))e\sin(\theta)}{p^2}+\frac{p^2}{(1+e\cos^2(\theta))^2}}} \tag{12.1.357}$$

There is another famous and simple relation of the radial velocity named the vis-viva equation that we will in the section of Aerospace Engineering at page 8619:

$$v=\sqrt{GM\left(\frac{2}{r}-\frac{1}{a}\right)} \tag{12.1.358}$$

12.1.6.2 Second Binet Formula (radial acceleration)

Let us now see the approach based on the radial acceleration which, while being more elegant, allows us to get a result less fine-tuned on the ellipse parameters.

So we start from the expression of the acceleration in polar coordinates (see section Vector Calculus page 1863):

$$\vec{a}=\left(\frac{\mathrm{d}r}{\mathrm{d}t^2}\right)\vec{u}_r+\left(2\frac{\mathrm{d}r}{\mathrm{d}t}\frac{\mathrm{d}\theta}{\mathrm{d}t}+r\frac{\mathrm{d}^2\theta}{\mathrm{d}t^2}\right)\vec{u}_\theta \tag{12.1.359}$$

We can simplify the writing of the second term:

$$2\frac{\mathrm{d}r}{\mathrm{d}t}\frac{\mathrm{d}\theta}{\mathrm{d}t}+r\frac{\mathrm{d}^2\theta}{\mathrm{d}t^2}=\frac{1}{r}\frac{\mathrm{d}}{\mathrm{d}t}\left(r^2\frac{\mathrm{d}\theta}{\mathrm{d}t}\right) \tag{12.1.360}$$

Now we have seen just above that:

$$r^2\frac{\mathrm{d}\theta}{\mathrm{d}t}=K=c^{te} \tag{12.1.361}$$

and so:

$$\frac{1}{r}\frac{\mathrm{d}}{\mathrm{d}t}\left(r^2\frac{\mathrm{d}\theta}{\mathrm{d}t}\right)=0 \tag{12.1.362}$$

Then the acceleration is reduced to:

$$\vec{a}=\left(\frac{\mathrm{d}r}{\mathrm{d}t^2}-r\left(\frac{\mathrm{d}\theta}{\mathrm{d}t}\right)^2\right)\vec{u}_r \tag{12.1.363}$$

We can eliminate the time by writing:

$$\frac{\mathrm{d}r}{\mathrm{d}t}=\frac{\mathrm{d}r}{\mathrm{d}\theta}\frac{\mathrm{d}\theta}{\mathrm{d}t} \tag{12.1.364}$$

and:

$$\frac{\mathrm{d}^2r}{\mathrm{d}t^2}=\frac{\mathrm{d}}{\mathrm{d}\theta}\left(\frac{\mathrm{d}r}{\mathrm{d}\theta}\frac{\mathrm{d}\theta}{\mathrm{d}t}\right)\frac{\mathrm{d}\theta}{\mathrm{d}t} \tag{12.1.365}$$

Then we get:

$$\begin{aligned}\vec{a}&=\left(\frac{\mathrm{d}r}{\mathrm{d}t^2}\vec{u}_r-r\left(\frac{\mathrm{d}\theta}{\mathrm{d}t}\right)^2\right)\vec{u}_r=\left(\frac{\mathrm{d}}{\mathrm{d}\theta}\left(\frac{\mathrm{d}r}{\mathrm{d}\theta}\frac{\mathrm{d}\theta}{\mathrm{d}t}\right)\frac{\mathrm{d}\theta}{\mathrm{d}t}-r\left(\frac{\mathrm{d}\theta}{\mathrm{d}t}\right)^2\right)\vec{u}_r\\&=\left(\frac{\mathrm{d}}{\mathrm{d}\theta}\left(\frac{\mathrm{d}r}{\mathrm{d}\theta}\frac{K}{r^2}\right)\frac{\mathrm{d}\theta}{\mathrm{d}t}-r\left(\frac{K}{r^2}\right)^2\right)\vec{u}_r=\left(\frac{\mathrm{d}}{\mathrm{d}\theta}\left(\frac{\mathrm{d}r}{\mathrm{d}\theta}\frac{K}{r^2}\right)\frac{K}{r^2}-r\left(\frac{K}{r^2}\right)^2\right)\vec{u}_r\\&=\frac{K^2}{r^2}\left(\frac{\mathrm{d}}{\mathrm{d}\theta}\left(\frac{\mathrm{d}r}{\mathrm{d}\theta}\frac{1}{r^2}\right)-\frac{1}{r}\right)\vec{u}_r=\frac{K^2}{r^2}\left(\frac{\mathrm{d}}{\mathrm{d}\theta}\left(-\frac{\mathrm{d}\left(\dfrac{1}{r}\right)}{\mathrm{d}\theta}\right)-\frac{1}{r}\right)\vec{u}_r\\&=-\frac{K^2}{r^2}\left(\frac{\mathrm{d}^2}{\mathrm{d}\theta^2}\left(\frac{1}{r}\right)+\frac{1}{r}\right)\vec{u}_r\end{aligned}\tag{12.1.366}$$

And so it comes to the standard "Binet's second formula":

$$\boxed{a=-\frac{K^2}{r^2}\left(\frac{\mathrm{d}^2}{\mathrm{d}\theta^2}\left(\frac{1}{r}\right)+\frac{1}{r}\right)}\tag{12.1.367}$$

But according to Newton's second law and his law of gravitation, we have:

$$F=ma=\frac{GMm}{r^2}\Rightarrow=\frac{GM}{r^2}=\frac{\mu}{r^2}\tag{12.1.368}$$

We then get another form of the Binet's second formula:

$$\frac{\mu}{r^2}=-\frac{K^2}{r^2}\left(\frac{\mathrm{d}^2}{\mathrm{d}\theta^2}\left(\frac{1}{r}\right)+\frac{1}{r}\right)\tag{12.1.369}$$

Or after simplification and choosing the sign of the acceleration at our convenience to get rid of the "-" sign, we have:

$$\mu=K^2\left(\frac{\mathrm{d}^2}{\mathrm{d}\theta^2}\left(\frac{1}{r}\right)+\frac{1}{r}\right)\tag{12.1.370}$$

By isolating the constants, we get:

$$\frac{\mathrm{d}^2}{\mathrm{d}\theta^2}\left(\frac{1}{r}\right)+\frac{1}{r}=\frac{\mu}{K^2}\tag{12.1.371}$$

After a change of variables we recognize the particular case of a differential equation of the second order we have already met several times so far in various sections of this textbook and that will meet again:

$$\frac{\mathrm{d}^2u}{\mathrm{d}\theta^2}+u=\frac{u}{K^2}\tag{12.1.372}$$

As it is customary, however, we will show the details of the resolution. The equation without second member is (see section Differential and Integral Calculus page 1610):

$$\frac{\mathrm{d}^2u}{\mathrm{d}\theta^2}+u=0\tag{12.1.373}$$

We then have the discriminant that is negative since:

$$\frac{-a\pm\sqrt{a^2-4b}}{2}=\frac{\sqrt{-4}}{2}=\sqrt{-1} \tag{12.1.374}$$

We then saw in the section of Differential and Integral Calculus (see page 1610), that in this situation the solution of the homogeneous equation was of the form:

$$y_h=C'e^{\alpha x}\cos(\beta t-\phi) \tag{12.1.375}$$

Thus in the situation we are concerned, we have:

$$u_h=Ae^{0\cdot\theta}\cos(1\cdot\theta-\theta_0)=A\cos(\theta-\theta_0) \tag{12.1.376}$$

We inject the solution into the homogeneous differential equation with second member:

$$\frac{\mathrm{d}^2A\cos(\theta-\theta_0)}{\mathrm{d}\theta^2}+A\cos(\theta-\theta_0)=\frac{\mu}{K^2} \tag{12.1.377}$$

and we see immediately that for the equality to be satisfied, the general solution is:

$$u=\frac{1}{r}=A\cos(\theta-\theta_0)+\frac{\mu}{K^2} \tag{12.1.378}$$

Or after rearrangement:

$$r=\frac{\dfrac{K^2}{\mu}}{1+\dfrac{K^2A}{\mu}\cos(\theta-\theta_0)}=\frac{p}{1+e\cos(\theta-\theta_0)} \tag{12.1.379}$$

And choosing the initial angle as zero, so we find well:

$$\boxed{r=\frac{p}{1+e\cos(\theta)}} \tag{12.1.380}$$

at the difference with the first method of resolution that the value of the constant A is unknown.

Let us now come back on:

$$u=\frac{1}{r}=A\cos(\theta-\theta_0)+\frac{\mu}{K^2} \tag{12.1.381}$$

By expliciting:

$$\frac{1}{r}=A\cos(\theta-\theta_0)+\frac{GM}{\left(r^2\dfrac{\mathrm{d}\theta}{\mathrm{d}t}\right)^2} \tag{12.1.382}$$

And as (see section Classical Mechanics page 3280):

$$r\frac{\mathrm{d}\theta}{\mathrm{d}t}\cong v_{\text{rot}} \tag{12.1.383}$$

So if we choose a particular point of reference of the path (not necessarily circular path), we have:

$$r_0\frac{\mathrm{d}\theta}{\mathrm{d}t}\cong v_0 \tag{12.1.384}$$

Then we have:

$$\frac{1}{r}\cong A\cos(\theta-\theta_0)+\frac{GM}{r_0^2v_0^2} \tag{12.1.385}$$

If we put the phase shift as zero relatively to the reference chosen radius earlier above, the expression simplifies to:

$$\frac{1}{r}\cong A\cos(\theta)+\frac{GM}{r_0^2v_0^2} \tag{12.1.386}$$

To determine the constant A, we place ourselves in the case where $\theta=0$ and imposes that the radius r is the initial radius measured when this angle is zero. Then we have:

$$\frac{1}{r_0}\cong A+\frac{GM}{r_0^2v_0^2} \tag{12.1.387}$$

This implies immediately:

$$\boxed{\frac{1}{r}\cong\frac{1}{r_0}\left(1-\frac{GM}{r_0v_0^2}\right)\cos(\theta)+\frac{GM}{r_0^2v_0^2}} \tag{12.1.388}$$

Thus after elementary rearrangements and simplifications:

$$r\cong\frac{\dfrac{r_0^2v_0^2}{GM}}{1+(r_0v_0^2-GM)\cos(\theta)} \tag{12.1.389}$$

And therefore we have a direct correspondence:

$$e\cong r_0v_0^2-GM \tag{12.1.390}$$

And as the eccentricity e is known for a circular, parabolic, elliptical or another trajectory of the conical type... it gets us very easy to deduce the velocity at the particular point of the initial radius r of the studied object.

The closest distance of the object orbiting around its central star (focus), will be given by the value that can takes r in the relation:

$$\frac{1}{r}\cong\frac{1}{r_0}\left(1-\frac{GM}{r_0v_0^2}\right)\cos(\theta)+\frac{GM}{r_0^2v_0^2} \tag{12.1.391}$$

if we impose $\theta=0$.

In the case of an elliptical orbit it is the "perigee" to be assimilated to the initial radius as the point where the measurement of the radial velocity was the most accurate.

The farthest distance from the focus will be given by putting the angle as being $180°$ (π) and then we name it "apogee".

12.1.6.3 Keplerian orbital period

The Kepler's law of equal areas allows, as we already know, to calculate the Keplerian orbital period T. In fact, the area S of the ellipse being equal to $S = \pi ab$ (see section Geometric Shapes page 2917) and having already determined during our definition of the angular momentum that (see section Classical Mechanics page 3244):

$$\frac{\mathrm{d}S}{\mathrm{d}t} = \frac{K}{2} \tag{12.1.392}$$

It comes naturally:

$$\frac{\pi ab}{T} = \frac{K}{2} \tag{12.1.393}$$

Moreover, the study of conics (see section Analytical Geometry page 2779) has showed us that:

$$p = \frac{b^2}{a} = \frac{T^2 K^2}{4\pi^2 a^3} \tag{12.1.394}$$

and we have defined above:

$$p = \frac{K^2}{\mu} \tag{12.1.395}$$

So we have the relation:

$$T = \sqrt{\frac{a^3 4\pi^2}{\mu}} \tag{12.1.396}$$

and then we fall back again on the third Kepler's law:

$$\frac{a^3}{T^2} = \frac{GM}{4\pi^2} \tag{12.1.397}$$

which validates our previous calculations.

Obviously the latter relation is only available for T where the corresponding speed is non relativistic otherwise we have to use General Relativity tools (see page 5720).

Before we continue... here are some useful data for this section and for that for Aerospace Engineering (i.e. "space dynamics") relatively to our knowledge in the state of year 12018 according to holocene calendar (various sources were used for these tables but the main one is Wikipedia):

Mercury ☿	
Mass	$3.3011 \cdot 10^{23}$ [kg]
Mean density	$5.427 \left[\text{g} \cdot \text{cm}^{-3}\right]$
Mean radius	$2,439.7$ [km]

12.1.6.4 Average distance between two planets

Let us consider two planets with the special and ideal case where the orbit are perfectly circular around a given star like below:

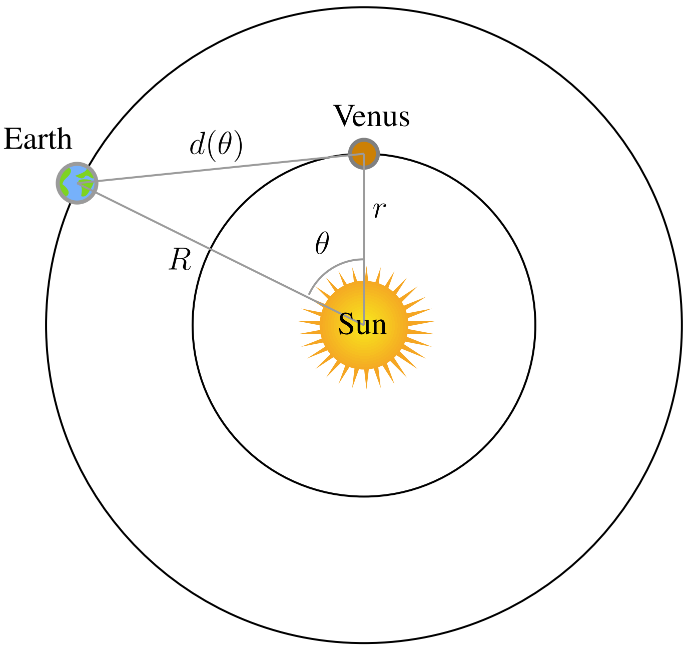

Figure 12.57: **Configuration for the average distance between to planets**

Using the law of cosines proven in the section of Trigonometry at page 2524, we have:

$$d^2(\theta)=R^2+r^2-2Rr\cos(\theta) \qquad (12.1.398)$$

Hence:

$$d(\theta)=\sqrt{R^2+r^2-2Rr\cos(\theta)} \qquad (12.1.399)$$

The average distance is obviously given by:

$$\bar{d}=\frac{1}{2\pi}\int\limits_0^{2\pi} d(\theta)\mathrm{d}\theta \qquad (12.1.400)$$

Therefore:

$$\bar{d}=\frac{1}{2\pi}\int\limits_0^{2\pi} d(\theta)\mathrm{d}\theta=\frac{1}{2\pi}\int\limits_0^{2\pi}\sqrt{R^2+r^2-2Rr\cos(\theta)}\mathrm{d}\theta \qquad (12.1.401)$$

It's quite a complex integral and as far as we know it must be solved analytically!

Let us raise now more sophisticated mathematical question: What is the true average distance of a planet from the Sun? More generally, we ask: For any ellipse, what is the true average distance from all points $P(x,y)$ on the ellipse to a particular focus, $F(c,0)$?

We have proven in the section of Analytical Geometry (see page 2783) that the distance of the path of an ellipse (where $e<1$) to one of its focus was given by:

$$d(\theta)=\overline{PF}=a(1-e\cos(\theta)) \tag{12.1.402}$$

The average distance to a focus is therefore:

$$\bar{d}=\frac{1}{2\pi}\int_0^{2\pi}a(1-e\cos(\theta))\mathrm{d}\theta=\frac{1}{2\pi}\left(a\theta-ea\sin(\theta)\right)\Big|_0^{2\pi}=\frac{1}{2\pi}\left(a2\pi-ea\right)=a\left(1-\frac{e}{2\pi}\right) \tag{12.1.403}$$

Notice in the special case of a circle where $a=R$ and $e=0$ we have as expected $\bar{d}=R$.

12.1.6.5 Classical deflection of light (light bending)

The calculations done previously can be applied to an interesting case: the deflection of light by a star in the Newtonian interpretation (of course!).

Warning!!! Newton did not know at its time that the photon was mass-less. The following developments are therefore a wrong approach in our time and should be taken with precaution but are still taught today because it allows students that do not yet studied General Relativity or that will never study it (in the section on General Relativity, the reader will find the contemporary detailed proof of the deflection of light that is a whole other level) to have a first approach... it's like everything in physics! Until we have reached the level of the university degree, we learn many things "wrong" because oversimplified. Then at the Master or PhD level, we learn a little more realistic and valid theories.

Well this being recalled (following the remark of one of our reader), so we have proved above for recall that:

$$r=\frac{p}{1+e\cos(\theta)} \qquad (12.1.404)$$

In the case of a photon, we tend to put that $r\rightarrow+\infty$ (thus a hyperbolic trajectory) and therefore this requires that in the previous relation we have (which is equivalent to saying that e is strictly greater than the unit as required by the hyperbolic trajectory):

$$\cos(\theta)=-\frac{1}{e} \qquad (12.1.405)$$

By putting $\varphi=2\theta-\pi$ the elementary trigonometric relations (see section Trigonometry page 2519) give us:

$$\sin\left(\frac{\varphi}{2}\right)=\sin\left(\theta-\frac{\pi}{2}\right)=-\cos(\theta)=\frac{1}{e} \qquad (12.1.406)$$

and therefore still using trigonometric identities:

$$e^2=\frac{1}{\sin^2\left(\dfrac{\theta}{2}\right)}=1+\cot\left(\frac{\theta}{2}\right) \qquad (12.1.407)$$

Therefore:

$$\cot\left(\frac{\theta}{2}\right)=e^2-1 \qquad (12.1.408)$$

And we know that:

$$e^2=1+\frac{2EK^2}{\mu^2} \qquad (12.1.409)$$

Hence:

$$e^2-1=\frac{2EK^2}{\mu^2} \qquad (12.1.410)$$

neglecting the potential energy of the photon since $r \rightarrow +\infty$ (caution!!! Let us recall that according to what we saw in the section of Special Relativity, the photon has no mass strictly speaking but Newton knew nothing about this at his time!):

$$E=\frac{1}{2}v^2 \tag{12.1.411}$$

Therefore:

$$\cot^2\left(\frac{\theta}{2}\right)=\frac{v^2K^2}{G^2M^2} \tag{12.1.412}$$

Hence:

$$\tan^2\left(\frac{\theta}{2}\right)=\frac{G^2M^2}{v^2K^2} \tag{12.1.413}$$

After simplification:

$$\tan^2\left(\frac{\theta}{2}\right)=\frac{GM}{vK} \tag{12.1.414}$$

and as θ is assumed to be small, we have using the Taylor expansion (see section Sequences and Series page 1703) of the tangent function:

$$\tan^2\left(\frac{\theta}{2}\right)\cong\frac{\theta}{2} \tag{12.1.415}$$

So it finally comes:

$$\theta\cong\frac{2GM}{vK} \tag{12.1.416}$$

But, we have by definition:

$$K=r^2\frac{\mathrm{d}\theta}{\mathrm{d}t}=r^2\dot{\theta} \tag{12.1.417}$$

and we know that $v=\omega r=\dot{\theta}r$ (see section Classical Mechanics page 3280). Thus we have:

$$\theta\cong\frac{2GM}{v^2r} \tag{12.1.418}$$

If the particle is a photon passing flush to the surface of the Sun (actually a G2V-type star, aka yellow dwarf) then we have for the "classical deflection of light":

$$\boxed{\theta\cong\frac{2GM}{c^2R_{\odot}}} \tag{12.1.419}$$

A numerical application gives:

$$\theta\cong 4.237\cdot 10^{-6}\,[\text{rad}]\underset{\times\frac{360}{2\pi}}{=}2.427\cdot 10^{4\circ}\underset{\times 60\cdot 60}{=}0.87'' \tag{12.1.420}$$

Newtonian theory thus provides a 0.87 arc seconds deviation for a ray of light passing flush to the Sun's surface. Which is twice less than what can be observed experimentally and that gives the theory of General Relativity (see section General Relativity page 5800)!

Here is an Adobe Flash animation of what a light bulb light rays propagation in vacuum, ON, would look like:

The animation above will run for people having a PDF reader with Adobe Flash player installed and activated (otherwise see here: https://vimeo.com/575751871).

And here is an another Adobe Flash animation of what a light bulb light rays propagation in vacuum putted in the presence of a punctual mass, ON, would look like:

The animation above will run for people having a PDF reader with Adobe Flash player installed and activated (otherwise see here: https://vimeo.com/575750678).

12.1.6.6 Classical precession of perihelion (apsidal precession)

Before studying the precession of the orbits, we would recall that the gravitational field is a conservative and center field. This implies that the angular momentum (see section Classical Mechanics page 3244) is constant and that the path is held in a plane whose normal vector to the surface always maintains the same direction (the angular momentum vector is constant in norm and direction for recall!).

We will address here the analysis of the precession of the perihelion taking into account the results of the theory of Special Relativity (allowing it to be more accurate in the results and be able to apply these results to the orbiting electrons around the nucleus of the atom in the corpuscular model).

First let us recall that:

- The "perihelion" is the point of the orbit of a celestial body (planet, comet, etc.) that is closest to the star around which it rotates.
- The "aphelion" is the point in the orbit of an object (planet, comet, etc.) where it is farthest from the star around which it rotates.
- The "equinox[14]" is the moment (time) when the central star crosses the plane of the equator of the object that is in orbit around it.

Remark

When the Sun passes (actually a G2V-type star, aka yellow dwarf) from the southern hemisphere to the northern hemisphere of the Earth (in other words when the Sun is at the zenith at midday at the equator), it is the spring equinox (20 or 21 March) in the opposite direction, this is the autumn equinox (22 or 23 September). At these dates, there is equality of day and night all over the Earth from the point of view of the Equator.

---

[14] The name "equinox" also comes from the Latin: aequinoctium from aequus (equal) and nox from noctis (night), which means “night equal (to day)”.

Figure 12.58: **Solstices and Equinoxes depending on the latitude**

Contrary to an urban legend, the Sun can be at its zenith at noon (vertical) only between the tropics and even then, twice a year only! The zenith, figuratively speaking, is the highest degree of a situation. We can say, strictly speaking, that the Sun is "at its Zenith" at noon to mean that it is at the highest point of its apparent trajectory, but it is better to avoid it, as this is a source of error.

Obviously, the result we will get here is not complete, since, as we know, we had to wait the development of General Relativity to give the exact value of the perihelion precession of Mercury (that's why will come back on this subject further below).

To calculate the effect of precession, we will seek the equivalent of the Binet formulas seen above in relativistic form (we will see the classical form in the section of General Relativity). For this we proceed as follows:

The relativistic Lagrangian of the system is (see section Special Relativity page 5679):

$$L=T+V=\mu c^2(\gamma-1)+V \qquad (12.1.421)$$

Remark

We subtract then energy at rest because only interest us here the study of the kinetic and potential energy. The potential energy is summed in the Lagrangian above (which is not consistent with the practice) but we will reverse the sign later below during the developments.

With (see section Special Relativity page 5739 and Vector Calculus page 1863):

$$\gamma=\left(1-\frac{v^2}{c^2}\right)^{-1/2}=\left(1-\frac{\dot{r}+r^2\dot{\theta}^2}{c^2}\right)^{-1/2} \qquad (12.1.422)$$

and the reduce mass for recall:

$$\mu=\frac{mM}{m+M} \tag{12.1.423}$$

The angular moment:

$$\vec{b}=\mu\vec{r}\times\vec{v} \tag{12.1.424}$$

in relativistic form and applied to our study is:

$$\vec{b}=(\mu\gamma)r\times(\vec{\omega}\times\vec{r})=(\mu\gamma)\vec{r}\times(\vec{\omega}\times\vec{r}) \tag{12.1.425}$$

Taking the norm, we have without forgetting that in our study $\vec{\omega}\perp\vec{r}$ and therefore $(\vec{\omega}\perp\vec{r})\perp\vec{r}$:

$$b=(\mu\gamma)\omega r^2 \tag{12.1.426}$$

and let us recall that we have adopted the notation $\omega=\dot{\theta}$ (in case you forget the definition...). Which finally gives us:

$$b=(\mu\gamma)r^2\dot{\theta} \tag{12.1.427}$$

To establish the relativistic equivalent of the Binet formulas:

- We deduce the expression of the angular momentum:

$$\dot{\theta}=\mathrm{d}_t\theta=\frac{b}{\mu\gamma r^2} \tag{12.1.428}$$

- We seek for a relation of the type $\dot{r}=\dot{r}(\theta)$ (as the trajectory is a conic):

$$\dot{r}=\mathrm{d}_t r=\frac{b}{\mu\gamma r^2}\mathrm{d}_\theta r \tag{12.1.429}$$

  Indeed let us recall that in polar coordinates the speed is given by the following expression (see section Vector Calculus page 1863):

$$\vec{v}=\dot{\vec{r}}=\dot{r}\vec{e}_r+r\dot{\theta}\vec{e}_\theta \tag{12.1.430}$$

  That is to say, $\dot{r}=f(r,\theta)$. The latter expression gives us the possibility to write that:

$$\dot{r}=\frac{\mathrm{d}r}{\mathrm{d}t}=\frac{\mathrm{d}r}{\mathrm{d}\theta}\frac{\mathrm{d}\theta}{\mathrm{d}t}=\mathrm{d}_\theta r\dot{\theta} \tag{12.1.431}$$

- We seek a relation of the type $\ddot{r}=\ddot{r}(\theta)$:

$$\ddot{r}=\frac{b}{\mu\gamma r^2}\left[\mathrm{d}_\theta\left(\frac{b}{\mu\gamma r^2}\mathrm{d}_\theta r\right)\right] \tag{12.1.432}$$

From the equations obtained previously, we have successively:

$$\mu c^2(\gamma-1)+V=L\Leftrightarrow\gamma^2=\left(1+\frac{L-V}{\mu c^2}\right)^2 \tag{12.1.433}$$

Let us recall that we have defined in Special Relativity β and that by using the speed in polar coordinates:

$$\beta=\frac{v^2}{c^2}=\frac{\dot{r}^2+r^2\dot{\theta}^2}{c^2} \tag{12.1.434}$$

With the previous relations, this gives us:

$$\begin{aligned}\beta=\frac{v^2}{c^2}=\frac{\dot{r}^2+r^2\dot{\theta}}{c^2}=\frac{(\mathrm{d}_\theta r\dot{\theta})^2+r^2\left(\dfrac{b}{\mu\gamma r^2}\right)^2}{c^2}=\frac{\left(\mathrm{d}_\theta r\dfrac{b}{\mu\gamma r^2}\right)^2 r^2\left(\dfrac{b}{\mu\gamma r^2}\right)^2}{c^2}\\ =\frac{b^2}{\mu^2\gamma^2c^2}\left[\left(\frac{1}{r^2}\mathrm{d}_\theta r\right)^2+r^2\left(\frac{1}{r^2}\right)^2\right]=\frac{b^2}{\mu^2\gamma^2c^2}\left[\left(\frac{1}{r^2}\mathrm{d}_\theta r\right)^2+\frac{1}{r^2}\right]\end{aligned} \tag{12.1.435}$$

On the other hand:

$$\gamma^2=\frac{1}{1-\beta}=1+\frac{\beta}{1-\beta}=1+\gamma^2\beta \tag{12.1.436}$$

By substituting the prior previous relation in the latter:

$$\gamma^2=1+\cancel{\gamma^2}\frac{b^2}{\mu^2\cancel{\gamma^2}c^2}\left[\left(\frac{1}{r^2}\mathrm{d}_\theta r\right)^2+\frac{1}{r^2}\right] \tag{12.1.437}$$

By putting $u=1/r$ and as:

$$\frac{1}{r^2}\mathrm{d}_\theta r=\mathrm{d}_r\left(-\frac{1}{r}\right)\mathrm{d}_\theta r=\frac{\mathrm{d}\left(-\dfrac{1}{r}\right)}{\mathrm{d}r}\frac{\mathrm{d}r}{\mathrm{d}\theta}=-\mathrm{d}_\theta\left(\frac{1}{r}\right)=-\mathrm{d}_\theta u \tag{12.1.438}$$

The prior-previous relations becomes with this expression:

$$\gamma^2=1+\frac{b^2}{\mu^2c^2}\left[(-\mathrm{d}_\theta u)^2+u^2\right] \tag{12.1.439}$$

Equating this relation with that of the Lagrangian:

$$1+\frac{b^2}{\mu^2c^2}\left[\mathrm{d}_\theta^2 u+u^2\right]=\left(1+\frac{L-V}{\mu c^2}\right)^2 \tag{12.1.440}$$

Differentiating the latter relation relatively to θ:

$$\frac{b^2}{\mu^2c^2}\left[2\mathrm{d}_\theta(\mathrm{d}_\theta^2 u)+2u\mathrm{d}_\theta u\right]=2\left(1+\frac{L-V}{\mu c^2}\right)\left(-\frac{1}{\mu c^2}\mathrm{d}_\theta V\right) \tag{12.1.441}$$

Indeed, the Lagrangian is constant over time (the system is assumed to be conservative), we then have:

$$\mathrm{d}_\theta L=0 \tag{12.1.442}$$

and also:

$$\frac{\mathrm{d}}{\mathrm{d}\theta}\left(\frac{\mathrm{d}u(\theta)}{\mathrm{d}\theta}\frac{\mathrm{d}u(\theta)}{\mathrm{d}\theta}\right)=\frac{\mathrm{d}^2u(\theta)}{\mathrm{d}\theta^2}\frac{\mathrm{d}u(\theta)}{\mathrm{d}\theta}+\frac{\mathrm{d}u(\theta)}{\mathrm{d}\theta}\frac{\mathrm{d}^2u(\theta)}{\mathrm{d}\theta^2}=2\frac{\mathrm{d}}{\mathrm{d}\theta}u(\theta)\frac{\mathrm{d}^2}{\mathrm{d}\theta^2}u(\theta) \tag{12.1.443}$$

But if we continue:

$$-\frac{\mathrm{d}V}{\mathrm{d}\theta}=-\frac{\mathrm{d}V}{\mathrm{d}r}\frac{\mathrm{d}r}{\mathrm{d}\theta} \tag{12.1.444}$$

By referring to:

$$\frac{1}{r^2}\mathrm{d}_\theta r=-\mathrm{d}_\theta u\rightarrow \mathrm{d}_\theta r=-r^2\mathrm{d}_\theta u=-\frac{1}{u^2}\mathrm{d}_\theta u \tag{12.1.445}$$

So we get:

$$-\frac{\mathrm{d}V}{\mathrm{d}\theta}=\left(-\frac{\mathrm{d}V}{\mathrm{d}r}\right)\left(-\frac{1}{u^2}\mathrm{d}_\theta u\right)=\frac{1}{u^2}\frac{\mathrm{d}V}{\mathrm{d}r}\mathrm{d}_\theta u \tag{12.1.446}$$

That gives after a few simplifications:

$$\frac{b^2}{\mu^2c^2}\left[\mathrm{d}_\theta^2+u\right]=\left(1+\frac{L-V}{\mu c^2}\right)\frac{1}{\mu c^2}\frac{1}{u^2}\frac{\mathrm{d}V}{\mathrm{d}r} \tag{12.1.447}$$

By multiplying the latter by μ^2c^2/b^2:

$$\begin{aligned}\mathrm{d}_\theta^2u+u&=\frac{\mu^2c^2}{b^2}\left(1+\frac{L-V}{\mu c^2}\right)\frac{1}{\mu c^2}\frac{1}{u^2}\frac{\mathrm{d}V}{\mathrm{d}r}\\ \mathrm{d}_\theta^2u+u&=\frac{\mu}{b^2u^2}\left(1+\frac{L-V}{\mu^2}\right)\frac{\mathrm{d}V}{\mathrm{d}r}\end{aligned} \tag{12.1.448}$$

In a gravitational potential:

$$V=-G\frac{mM}{r}\rightarrow\frac{\mathrm{d}V}{\mathrm{d}r}=-\left(-G\frac{mM}{r^2}\right)=G\frac{mM}{r^2}=GmMu^2 \tag{12.1.449}$$

The Binet equation in Special Relativity is then:

$$\boxed{\mathrm{d}_\theta^2u+u=\frac{GmM\mu}{b^2}\left(1+\frac{L+GmMu}{\mu c^2}\right)} \tag{12.1.450}$$

To find a solution to this differential equation, we will group the variable u in the left side:

$$\begin{aligned}\mathrm{d}_\theta^2u+u&=\frac{GmM\mu}{b^2}+\frac{GmML}{b^2c^2}+\frac{G^2m^2M^2}{b^2c^2}u\\ \mathrm{d}_\theta^2u+u\left(1-\frac{G^2m^2M^2}{b^2c^2}\right)&=\frac{GmM\mu}{b^2}\left(1+\frac{L}{\mu c^2}\right)\end{aligned} \tag{12.1.451}$$

We put:

$$\Omega^2=\left(1-\frac{G^2m^2M^2}{b^2c^2}\right)\qquad\text{and}\qquad B=\frac{GmM\mu}{b^2}\left(1+\frac{L}{\mu c^2}\right) \tag{12.1.452}$$

The differential equation then can be written:

$$\mathrm{d}_\theta^2u+\left(\Omega^2u-B\right)=0 \tag{12.1.453}$$

We put:

$$\left(\Omega^2 u - B\right) = W \tag{12.1.454}$$

By taking the second derivative:

$$\Omega^2 \mathrm{d}_\theta^2 u = \mathrm{d}_\theta^2 W \Leftarrow \mathrm{d}_\theta^2 u = \frac{1}{\Omega^2}\mathrm{d}_\theta^2 W \tag{12.1.455}$$

We then get a simple differential equation:

$$\mathrm{d}_\theta^2 W + \Omega^2 W = 0 \tag{12.1.456}$$

whose solution is well known to us (see section Differential and Integral Calculus page 1610):

$$\begin{gathered} W = C_1 \cos(\Omega\theta) + C_2 \sin(\Omega\theta) = \Omega^2 u - B \\ \Rightarrow u = \frac{C_1}{\Omega^2}\cos(\Omega\theta) + \frac{C_2}{\Omega^2}\sin(\Omega\theta) + \frac{B}{\Omega^2} \end{gathered} \tag{12.1.457}$$

What can still be written as Ω^2 is a constant:

$$u = k_1 \cos(\Omega\theta) + k_2 \sin(\Omega\theta) + \frac{B}{\Omega^2} \tag{12.1.458}$$

with $k_1, k_2 = c^{te}$.

To determine the constants k_1, k_2, we place ourselves first in the situation for which $\theta = 0$, where r is minimal and therefore by u is maximum by definition.

We derivate relatively to θ:

$$(\mathrm{d}_\theta u)_{\theta=0} = \left[\underbrace{-k_1\Omega\sin(\Omega\theta)}_{=0} + \underbrace{-k_2\Omega\cos(\Omega\theta)}_{k_2=0}\right]_{\theta=0} = 0 \tag{12.1.459}$$

Therefore $k_2 = 0$ which makes that the relation:

$$u = k_1 \cos(\Omega\theta) + k_2 \sin(\Omega\theta) + \frac{B}{\Omega^2} \tag{12.1.460}$$

becomes:

$$\frac{1}{r} = k_1 \cos(\Omega\theta) + \frac{B}{\Omega^2} = \frac{B}{\Omega^2}\left(1 + \frac{\Omega^2 k_1}{B}\cos(\Omega\theta)\right) \tag{12.1.461}$$

Written differently (trying to return to a similar notation to that of the study of conic) then:

$$r = \frac{1}{\dfrac{B}{\Omega^2}\left(1 + \dfrac{k_1\Omega^2}{B}\cos(\Omega\theta)\right)} = \frac{\dfrac{\Omega^2}{B}}{1 + \dfrac{k_1\Omega^2}{B}\cos(\Omega\theta)} = \frac{p}{1 + e\cos(\Omega\theta)} \tag{12.1.462}$$

And the interest to write this in this way is to notice that we fall ultimately on the equation of an ellipse with p being the focal parameter of the conic, focal parameter given for recall by (see section Analytical Geometry page 2779):

$$p = a(1 - e^2) \tag{12.1.463}$$

where a is the half major axes of the ellipse.

Now let us put:

$$D=\frac{B}{\Omega^2} \qquad \text{and} \qquad \varepsilon=\frac{\Omega^2 k_1}{B} \tag{12.1.464}$$

At the first passage through the perihelion $\theta=0$ where:

$$\cos(\Omega\theta_0)=\cos(0)=1 \tag{12.1.465}$$

we have therefore:

$$\frac{1}{r}=D(1+\varepsilon) \tag{12.1.466}$$

At the second passage through the perihelion $\theta=2\pi$, we have:

$$\cos(\Omega\theta_1)=\cos(2\pi)=1 \tag{12.1.467}$$

we also have:

$$\frac{1}{r}=D(1+\varepsilon) \tag{12.1.468}$$

The trajectory is still an ellipse but the angle $\Omega\theta_0$ that was zero initially has become $\Omega\theta_1=2\pi$.

That is, if we have:

$$\theta_1=\theta_0+\Delta\theta \tag{12.1.469}$$

Therefore:

$$\Omega(\theta_0+\Delta\theta)-\Omega\theta=2\pi \tag{12.1.470}$$

Which gives us:

$$\Delta\theta=\frac{2\pi}{\Omega}=\frac{2\pi}{\sqrt{1-\dfrac{G^2m^2M^2}{b^2c^2}}} \tag{12.1.471}$$

Since $G^2 \ll c^2$, a development in Taylor series give us (see section Sequences and Series page 1703):

$$(1+x)^{-1/2}=1-\frac{1}{2}x+\frac{3}{8}x^2-\ldots \tag{12.1.472}$$

By limiting at the order 2:

$$\Delta\theta=2\pi\left(1+\frac{G^2m^2M^2}{2b^2c^2}\right)=2\pi+\frac{\pi G^2m^2M^2}{b^2c^2} \tag{12.1.473}$$

So in conclusion, there is an advancement of the perihelion taking place in the satellite's direction of rotation. For a repository located in the satellite's rotation plane, the trajectory is always an ellipse.

This advance is of:

$$\Delta\alpha = \frac{\pi G^2 m^2 M^2}{b^2 c^2} \tag{12.1.474}$$

by period. Either by expliciting the momentum given for reminder by:

$$b = rmv \tag{12.1.475}$$

It comes after simplification:

$$\boxed{\Delta\alpha = \frac{\pi G^2 M^2}{c^2 v^2 r^2}} \tag{12.1.476}$$

We will now allow us a rough approximation (mixture of relativistic and non-relativistic). If we consider the last relation, we have obtained during our developments of the Keplerian orbital trajectories the relation:

$$p = \frac{k^2}{\mu} = \frac{\|\vec{r} \times \vec{v}\|^2}{\mu} = \frac{b^2}{\mu m^2} = \frac{b^2}{GMm^2} \tag{12.1.477}$$

Therefore, injecting this into the relation of $\Delta\alpha$ we have:

$$\Delta\alpha = \frac{\pi G^2 m^2 M^2}{b^2 c^2} = \frac{\pi G^2 m^2 M^2}{pGMm^2 c^2} = \frac{\pi GM}{pc^2} \tag{12.1.478}$$

And we have also proved in the section of Analytical Geometry that:

$$p = a(1-e^2) \tag{12.1.479}$$

Therefore:

$$\boxed{\Delta\alpha = \frac{\pi GM}{a(1-e^2)c^2}} \tag{12.1.480}$$

Unfortunately, the numerical values for Mercury precession with $G = 6.674 \cdot 10^{-11}$ [$\text{m}^3 \cdot \text{kg}^{-1} \cdot \text{s}^{-2}$], $M = 1.99 \cdot 10^{30}$ [kg], $e = 0.260$, $a = 5.787 \cdot 10^{10}$ [m] and $T = 88$ [days], gives for a century (100 years of 365 days):

$$\Delta\alpha \frac{100 \cdot 365}{88} = \frac{\pi GM}{a(1-e^2)c^2} \frac{100 \cdot 365}{88} \cong 8.3778 \cdot 10^{-8} \cdot 414.772 \cong 3.47 \cdot 10^{-5}\ [\text{rad} \cdot \text{century}^{-1}] \tag{12.1.481}$$

Thus a precession of an angle of $7''$ century, and not the $43''$ as expected (...) there is therefore a lack of a factor 6 that only the General Relativity (see section General Relativity page 5800) makes possible to find. It is nevertheless interesting that Special Relativity already gives an orbit that precesses where Newton sees stable ellipse and that this approximation works for all the planets except Mercury (the planet closest to the Sun and undergoing the brunt of curvature of space-time).

A more detailed treatment taking into account that the Sun (actually a G2V-type star, aka yellow dwarf) is not a perfect sphere (even if its the nearest perfect spherical object in the Solar System) - there is an average variation of approximately only 6 kilometres between the equatorial radius and the polar radius of the Sun - also lead to a result that doesn't explain Mercury perihelion precession!

Remark

By applying exactly the same reasoning to corpuscular quantum physics (electrical potential) but with the ad hoc constants seen in the section of Electrostatics, we find:

$$\boxed{\Delta\alpha=\frac{\pi k^2 Z^2 e^4}{b^2 c^2}} \tag{12.1.482}$$

with $\vec{b}=\mu\vec{r}\times\vec{v}$ being the momentum and in the case of the atom, we will take (see section Corpuscular Quantum Physics page 4651):

$$b=\mu\gamma r^2\dot{\theta}=n_\theta\hbar \tag{12.1.483}$$

with reduced mass equal to:

$$\mu=\frac{mM}{m+M} \tag{12.1.484}$$

If the positions of the perihelion (and therefore the aphelion) of the Earth-Moon center of gravity (whose barycenter is located on average $4,671$ [km] from Earth's center) were constant over time, the duration of the different seasons would be constant. But the orbit of the center of gravity of Earth-Moon system also rotates in its plane in the forward direction at about $12''$ per year (a revolution is about $108,000$ years).

The precession of the equinox occurs in the opposite direction (retrograde direction) at about $50''$ per year (then a "precession equinox" revolution is about $26,000$ years). The combination of these two movements permits to calculate the period of the passage of the perihelion of the Earth by the direction of the vernal equinox, this period of about $21,000$ years and is named the "climatic precession".

Earth's orbit 10000 years from now
Indicated seasons
are for northern
hemisphere

Figure 12.59: Effects of precession on the seasons using the Northern Hemisphere terms (source: Wikipedia)

Caution! The illustration of the Earth revolving around the Sun in an elliptical orbit (a pronounced elliptical shape mainly due to the mathematical property of the cavalier perspective) is often wrongly associated with the seasons! As we will prove it later (see section Engineering page 8278), the eccentricity of the Earth's orbit plays very little role in temperature variations. The most important factor is actually the tilt of the Earth's rotation axis relative to its orbital plane around the Sun. This tilt is currently about 23.5 degrees. When one hemisphere is tilted toward the Sun, it receives more direct light and the days are longer, which results in warmer temperatures and summer in that hemisphere. Conversely, the other hemisphere, tilted away from the Sun, receives less direct light and the days are shorter, which results in colder temperatures and winter.

Indeed, every $10,500$ years (half period of climatic precession) aphelion changes from summer to winter. But even if the Earth-Sun distance is by far not the predominant factor in the nature of the seasons, the combination of the passage of the Earth in the winter in aphelion gives winters a little bit more harsh. Earth-Sun distance also depends on the variation in the eccentricity of Earth's orbit (due to external and inner planets). Thus, the ice ages are correlated with the minimum eccentricity of Earth's orbit (in the legend of the image below, the year is given based on the holocene calendar).

The work of the Celestial Mechanics Institute (France), since the 11970s (holocene calendar), would have to definitively confirm the theoretical predictions as what the eccentricity of Earth's orbit undergoes wide variations formed numerous periodicals under which the most important one have periods near $100,000$ years, and for one of them, a period of $400,000$ years. These results confirm the climatic variations of the Earth during the Quaternary (see section Weather & Marine Engineering page 8276). The paleoclimatology models indeed show the correlation between changes in the Earth's orbit elements and large quaternary glaciation.

Remark

In the case of the hydrogen atom (see section Corpuscular Quantum Physics page 4644), for the case dealing with relativistic model of Sommerfeld, with $n=1,n_\theta=1,Z=1$ and the fine-structure constant approximately equal to $1/137$, we get by applying the above relation by analogy but for the precession of the perihelion of the orbit of the electron:

$$\Delta\alpha=\pi\left(\frac{1}{137}\right)^2=1.67382\cdot 10^{-4}\,[\text{rad}\cdot\text{s}^{-1}] \qquad (12.1.485)$$

according to a corpuscular point view of matter!

12.1.7 Duration of the diurnal arc

A diurnal arc is the time, as expressed in right ascension (the celestial equivalent of longitude, measuring the East-West position of an astronomical object on the celestial sphere), it takes a planet, point, or degree to move from its rising point to its setting point. This takes place in many celestial bodies such as the Sun (actually a G2V-type star, aka yellow dwarf) and Moon.

So we will study here at the time length of the day, more exactly to the portion of day where we are illuminated by the Sun, as compared to the night when we are in the shade[15].

In reality, the Earth revolves around the Sun and describes an almost circular orbit at the same time it turns on itself around its axis that is tilted (actually) by about $23°27'$ relatively to its orbital plane[16] (the ecliptic):

Figure 12.61: **Representation of the rotation of the Earth on its orbit with its major phases**

The reader must remember that the ellipse in the illustration above is highly exaggerated for pedagogical reasons! In reality between the periapsis and the apoapsis there is only actually 3% of difference.

Remark

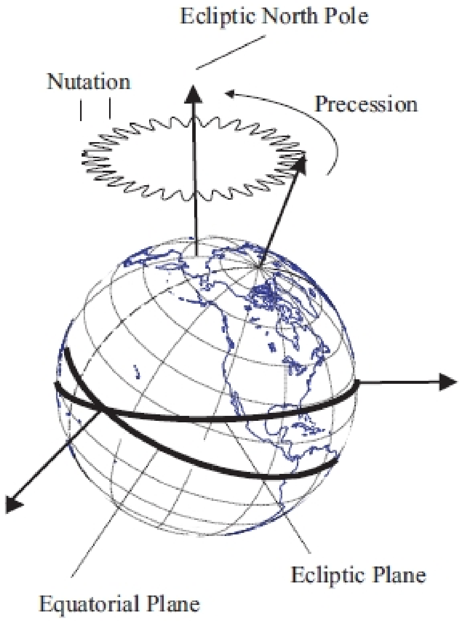
It is obvious that, given the complexity of the problem, we will simplify it by considering a circular orbit without variations (precession, nutation) of the axis of rotation of the Earth. We will assume that the Sun is reduced to a point (no dawn or twilight, etc.).

Let us first recall that the precession is the gradual change in direction of the axis of rotation of an object when a torque (force) is applied to it while the nutation is a periodic balancing of the axis of rotation of the Earth around its mean position in addition to the precession (see section Classical Mechanics page 3324).

---

[15] Thanks to Xavier Hubaut for these very friendly developments

[16] We measure Earth's axial inclination (tilt) using simple geometry and observing the Sun's angle at different times, primarily during solstices, by measuring shadows cast by a vertical pole (gnomon).



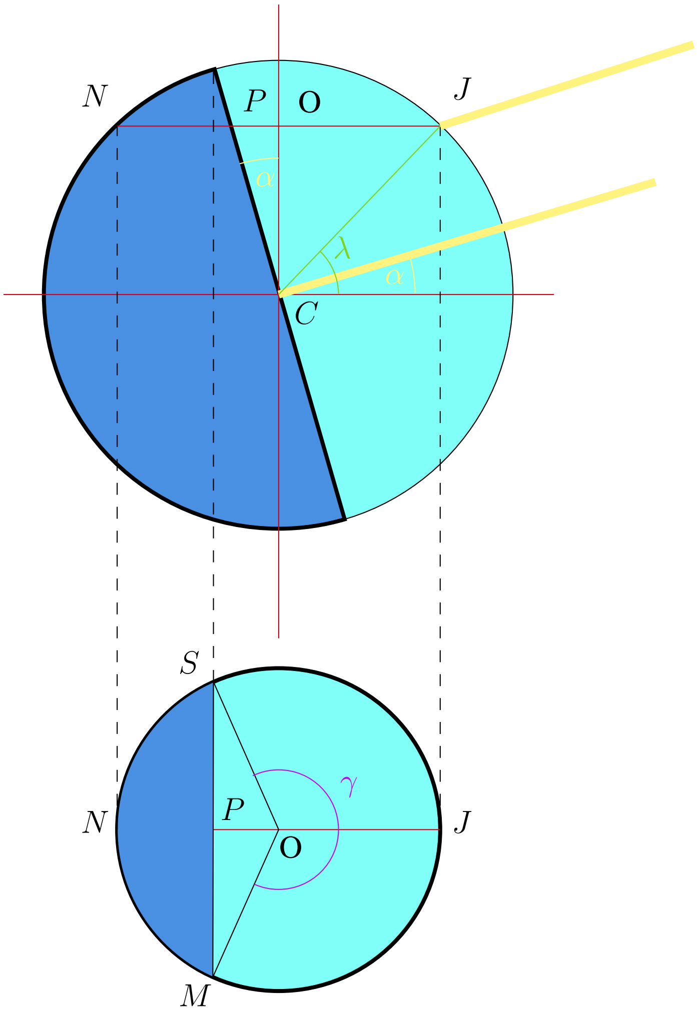
Let us represent the Earth with its vertical axis of rotation. Accordingly the equator will be located in a horizontal plane.

Suppose that day, the Earth is in such a position that the Sun's rays form an angle α with the equatorial plane (or conversely that the axis of the Earth form an angle with the equatorial plane). Notice that this angle α will always be according to actual measurements between $-23°27'$ and $+23°27'$ at least... at a human life time scale...

For our example we have chosen to focus our analysis on a day when α is positive. Thus, in the northern hemisphere, we are close to the summer solstice!

We are looking for the day length at a place located at latitude λ! To fix ideas, we place ourselves around Brussels at $50°$ north latitude.

Let us now consider the following figures where the first is a view of the side of Earth at a time t of its orbit when $\alpha > 0$ and the second in to a cylindrical cutting of diameter $\overline{NJ}$ (corresponding to the diameter of the parallel of Brussels) of Earth's volume Earth at this same moment:



In the figure above, C denotes the center of the Earth, and O the center of the parallel of Brussels.

Let us fix a time t and denote by M (morning) and S (evening) the two points of the parallel of Brussels where the Sun rises and sets (these points will be considered fixed whatever the moment t, which is obviously wrong relatively to the reality), while J (day) and N (night) will be the points where it is noon and midnight respectively.

P will be the point on the disc corresponding to the Brussels parallel where the meridian noon plane (the plan which of the sides is $\overline{NJ}$) cut the line $\overline{MS}$.

Finally, γ designate the angle $\widehat{M\text{O}S}$ (where O is the center of the disk generated by the parallel of Brussels) behind the illuminated part by the Sun and r designate the radius $S\text{O}=M\text{O}$.

To simplify the problem, let us also assume... that during 24 hours the Earth rotates on itself without changing the position of its axis of rotation relative to the Sun....

The angle γ can be calculated by noting that $\overline{\text{O}P}$ is, in absolute value equal to:

$$\overline{P\text{O}}=\overline{S\text{O}}\cos\left(\pi-\frac{\gamma}{2}\right)=\overline{M\text{O}}\cos\left(\pi-\frac{\gamma}{2}\right)=r\cos\left(\pi-\frac{\gamma}{2}\right) \tag{12.1.486}$$

where r represents for recall the radius of the parallel of Brussels.

Using the properties of trigonometric functions (see section Trigonometry page 2519), we have:

$$\overline{PO}=-r\cos\left(\frac{\gamma}{2}\right) \tag{12.1.487}$$

But we still need to inject the parameter α. Knowing the latitude λ of Brussels, we have:

$$r=\overline{OJ}=R\cos(\lambda) \tag{12.1.488}$$

where R is the radius of the Earth.

We have also:

$$\overline{CO}=R\sin(\lambda) \tag{12.1.489}$$

and in the triangle COP:

$$\overline{PO}=\overline{CO}\tan(\alpha)=R\sin(\lambda)\tan(\alpha) \tag{12.1.490}$$

Finally, by comparing the values obtained for $\overline{PO}$, we get:

$$\left.\begin{array}{l}\overline{PO}=R\sin(\lambda)\tan(\alpha)\\ \overline{PO}=-r\cos\left(\frac{\gamma}{2}\right)\end{array}\right\}\Rightarrow R\sin(\lambda)\tan(\alpha)=-r\cos\left(\frac{\gamma}{2}\right) \tag{12.1.491}$$

and as:

$$r=\overline{OJ}=R\cos(\lambda) \tag{12.1.492}$$

We finally get:

$$R\sin(\lambda)\tan(\alpha)=-R\cos(\lambda)\cos\left(\frac{\gamma}{2}\right) \tag{12.1.493}$$

and therefore:

$$\gamma=-2\arccos(\tan(\lambda)\tan(\alpha)) \tag{12.1.494}$$

At the equinoxes (that is to say when the equator coincides with the ecliptic plane for recall...) we have $\alpha=0$ and therefore:

$$\gamma=-2\arccos(\tan(\lambda)\tan(\alpha))=-2\arccos(\tan(\lambda)\cdot 0)=-2\arccos(0)=-\pi \tag{12.1.495}$$

However, as we have specified it at the beginning, we must take the absolute value thus:

$$\gamma=\pi \tag{12.1.496}$$

In other words, whatever the latitude we take, the angle formed by the night area is equal to the angle formed by the day area at equinoxes (both being equal to π).

Let us now consider the summer solstice, when $\alpha=23°27'$ still considering the latitude of Brussels $\lambda=50°$, we have:

$$\gamma=-2\arccos(\tan 50°)\tan(23°27'))=-2\arccos(0.51695)=-2\arccos(0)\cong-118° \tag{12.1.497}$$

This translated is translated into hours by:

$$-118^\circ\frac{24}{360}\cong -7.9 \tag{12.1.498}$$

So the 24-hour day loses 7.9 hours. Which is equivalent to a day light of approximately 16 hours.

In summary to calculate the duration of a "day", it is enough to know two things: the latitude and the angle at which the Sun (actually a G2V-type star, aka yellow dwarf) falls on the plane of the equator to the chosen date. The value of this angle is well known at the equinoxes (it is 0°) and to the solstices (it is $+23^\circ 27'$ and $-23^\circ 27'$).

But what about the other dates?

The answer is quite simple. Let us imagine, sitting on the Sun watching throughout the year towards the center of the Earth.

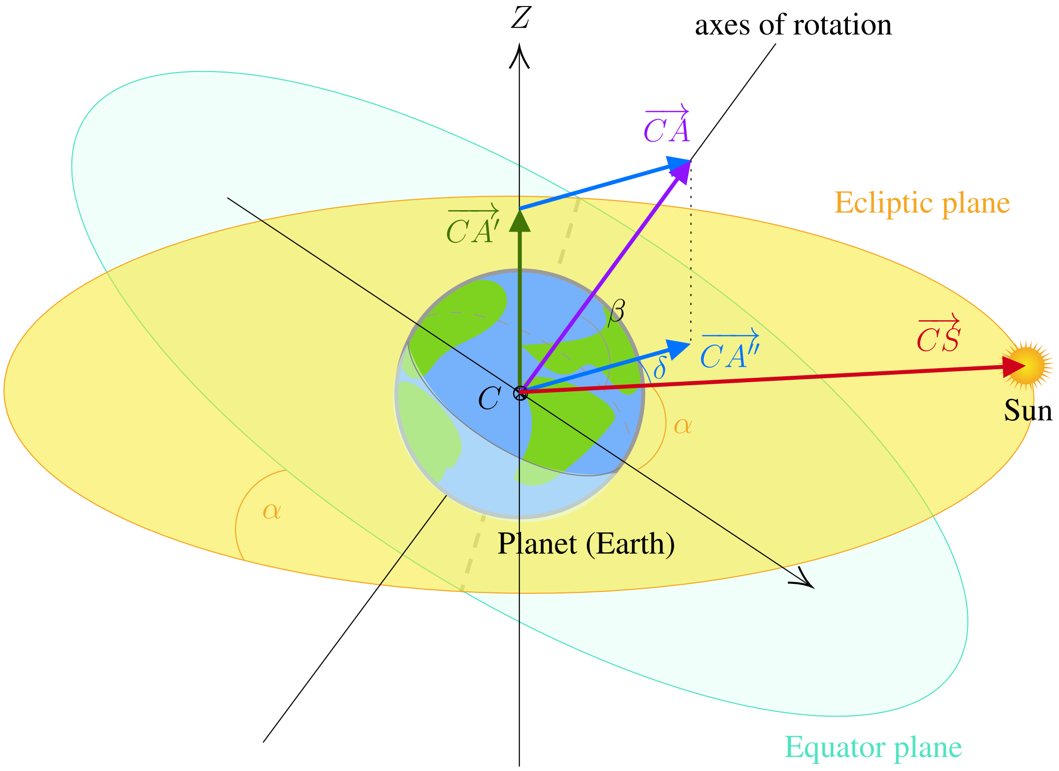
During its rotation around the Sun (the binomial centroid in fact), the axis of rotation of the Earth maintains its inclination to the ecliptic. Seen from the Sun, this axis revolve around normal to the plane of the ecliptic and therefore describe a cone whose half apex angle is $23^\circ 27'$ (see figure below).

The angle of attack α of the sunlight on the equator therefore vary according to the date δ (we associate to the date, the angle δ travelled by the Earth on its orbit, from its position at the spring equinox).

Therefore, the angle α vary according to the date δ sinusoidally.

For those who are perhaps not convinced by this semi-intuitive reasoning, here's another approach:

For readability of the diagram, we have greatly exaggerated the angle of the axis of rotation of the Earth with the ecliptic (and obviously nothing is to scale...!):



Given C the Earth's center, A the end of a unitary vector $\overrightarrow{CA}$ oriented directed along the axis of rotation of the Earth (i.e. perpendicular to the plane of the equator) and another unit vector $\overrightarrow{CS}$ directed toward the Sun. Given now α the angle of the radius $\overline{CS}$ with the plane of the equator and β the angle between the unit vectors $\overrightarrow{CA}$ and $\overrightarrow{CS}$. Then we have:

$$\overrightarrow{CS}\circ\overrightarrow{CA}=\underbrace{||\overrightarrow{CS}||||\overrightarrow{CA}||}_{=1}\cos(\beta)=\cos\left(\frac{\pi}{2}-\alpha\right)=\sin(\alpha) \qquad (12.1.499)$$

Indeed, the vector $\overrightarrow{CA}$ being perpendicular to the plane of the equator, it forms a right angle with it. Therefore since the angle β is the angle between this vector and the ecliptic, the angle α is then the complementary angle.

Therefore we have:

$$\overrightarrow{CS}\circ\overrightarrow{CA}=\sin(\alpha) \qquad (12.1.500)$$

Let us decompose now $\overrightarrow{CA}$ in the sum of $\overrightarrow{CA'}$ directed perpendicular to the ecliptic plane and of $\overrightarrow{CA''}$ located in the ecliptic plane:

$$\begin{aligned}\overrightarrow{CS}\circ\overrightarrow{CA}&=\underbrace{\overrightarrow{CS}\circ\overrightarrow{CA'}}_{\overrightarrow{CS}\perp\overrightarrow{CA'}\Rightarrow=0}+\overrightarrow{CS}\circ\overrightarrow{CA''}=\overrightarrow{CS}\circ\overrightarrow{CA''}=\underbrace{||\overrightarrow{CS}||}_{=1}||\overrightarrow{CA''}||\cos\left(\widehat{BCA''}\right)\\&=||\overrightarrow{CA''}||\cos\left(\widehat{BCA''}\right)=\underbrace{||\overrightarrow{CA}||}_{=1}\cos(\beta)\cos\left(\widehat{BCA''}\right)=\cos\left(\frac{\pi}{2}-\alpha\right)\cos\left(\widehat{BCA''}\right)\\&=\sin(\alpha)\cos\left(\widehat{BCA''}\right)\end{aligned} \qquad (12.1.501)$$

Therefore:

$$\overrightarrow{CS}\circ\overrightarrow{CA}=\sin(\alpha)\cos\left(\widehat{BCA''}\right)=\sin(23°27')\cos\left(\widehat{BCA''}\right) \tag{12.1.502}$$

But (hence the number of days in the interval $[0,365[$ must be converted into an angle in the range $[0,2\pi[$):

$$\cos\left(\widehat{BCA''}\right)=\cos\left(\frac{\pi}{2}-\delta\right)=\sin(\delta) \tag{12.1.503}$$

So finally:

$$\overrightarrow{CS}\circ\overrightarrow{CA}=\sin(23°27')\sin(\delta) \tag{12.1.504}$$

and as we have proved that:

$$\overrightarrow{CS}\circ\overrightarrow{CA}=\sin(\alpha) \tag{12.1.505}$$

We finally get:

$$\sin(\alpha)=\sin(23°27')\sin(\delta)=0.3979\sin(\delta) \tag{12.1.506}$$

Now the problem is solved and the daylight time duration will depend on two variables: the date δ and the latitude λ.

So we just have now to take again the relation:

$$\gamma=-2\arccos(\tan(\lambda)\tan(\alpha)) \tag{12.1.507}$$

and to inject in it the new result to get a first simple version of the "equation of sunrise" (EoS):

$$\boxed{\gamma=|-2\arccos\left(\tan(\lambda)\tan(\arcsin(\sin(23°27')\sin(\delta)))\right)|} \tag{12.1.508}$$

From the latter we get the duration of the day as before (if the result of γ is provided in degrees):

$$t_{\text{day}}(\delta,\lambda)=24+\frac{-2\arccos\left(\tan(\lambda)\tan(\arcsin(\sin(23°27')\sin(\delta)))\right)\cdot 24}{360} \tag{12.1.509}$$

Or for example for Brussels we get in Microsoft® Excel® 16.0.17231:

```
=24+DEGREES(-2*ACOS(TAN(RADIANS(50))*TAN(ASIN(SIN(RADIANS(23)
        *SIN(RADIANS(90)))))))*24/360=16.0518
```

With computer tools at our disposal, we can easily plot the value γ. For example, we have below the variations in the length of the day over a year at latitudes of 0 to $90°$ spread by 10 by $10°$:

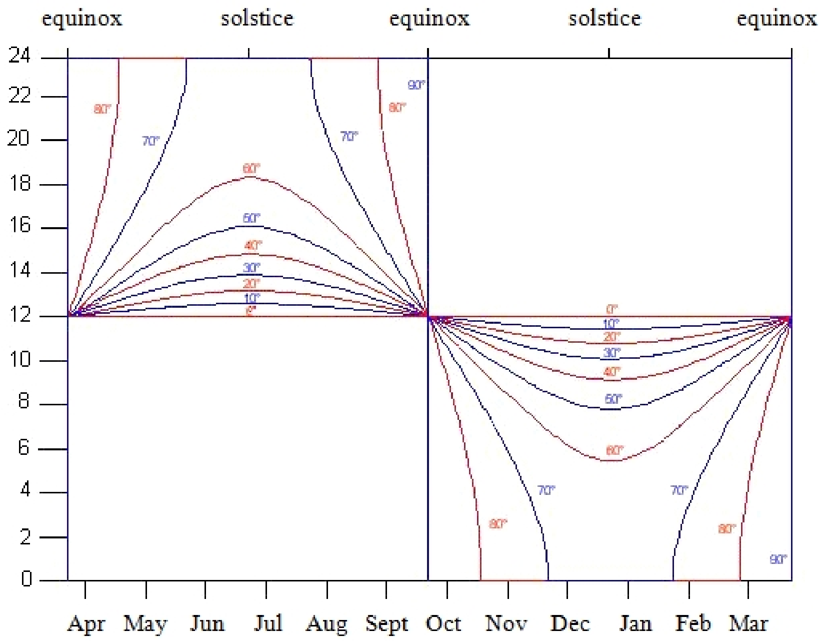


Figure 12.62: **Equation of Sunrise**

From the latitude of the Arctic Circle, we see, in summer, periods with uninterrupted Sun (midnight Sun) and in winter whole days of night.

For Brussels (latitude = $50°$) we see from the figure that the length of the day varies approximately between the values of 16 [h] (summer solstice) and 8 (winter solstice).

The length of the day at the equator is nearly always the same, staying close to 12 hours of daylight and 12 hours of darkness every day of the year.

At the equinox all places on Earth have the same number 12 hours of daylight and 12 hours of darkness !

12.1.7.1 Evolution of diurnal arc (i.e. Earth-Moon distance)

In many books or documentaries you can read or listen the following statements:

- The rotational movement of the Earth on itself slows down by the tidal effect
- The distance from Earth to Moon increases
- That these two effects are related

Let us see if we can prove this link and verify the orders of magnitude of these observed effects.

If we want to describe it completely, the movement of the Moon is a three-body problem (Earth, Moon, Sun) subjected to several hundred periodic or secular disturbances, which makes it very difficult. So the tides on Earth are caused mainly by the Moon, but the Sun also intervenes: the ratio of the gravitational forces exerted by the Moon and by the Sun on a body of water on the surface of the Earth is 2.2.

For what interests us, however, we will consider the Earth-Moon system as isolated in space. This is because we are studying the movement of rotation on itself of this system: in a way we relate the action of the Sun to the Earth-Moon center of mass. In addition, we are not studying how the tides slow down the rotation of the Earth: this slowing down being observed, we want to show how a slowing down of the Moon follows.

Second approximation: in the rotational motion, we will confuse the center of mass of the system with the center of the Earth, and the Moon will be assumed to describe an elliptical Keplerian orbit around the center of the Earth.

The physical law that must be applied is therefore simple: the angular momentum $\vec{b}$ of the Earth-Moon system is conserved. However, this total angular momentum $\vec{b}_{\text{tot}}$ is, in the Galilean coordinate system of the center of mass, the sum of three terms:

1. The angular momentum of rotation of the Earth on itself (considering it as a perfect ball), $\vec{b}_{♁}$. It is directed along the axis of the poles and therefore forms an angle of $23°27'$ with the perpendicular to the plane of the ecliptic. In intensity it is:

   $$b_{♁}=J_{♁}\omega_{♁}\cong\frac{2}{5}M_{♁}R_{♁}^2\omega_{♁}=\frac{2}{5}M_{♁}R_{♁}^2\frac{2\pi}{T_{♁}} \tag{12.1.510}$$

   where $M_{♁}\cong 6\cdot 10^{24}$ [kg], $R_{♁}\cong 6.4\cdot 10^{6}$ [m] and $T_{♁}=86,164$ [s].

2. The angular momentum of rotation of the Moon on itself (also considered as a perfect sphere) $\vec{b}_{\bigcirc}$ it is directed along the axis of rotation of the Moon, which forms an angle of $6°$ with the normal to the plane of the lunar orbit, itself inclined by $5°$ on the plane of the ecliptic. It is worth in intensity:

   $$b_{\bigcirc}=J_{\bigcirc}\omega_{\bigcirc}\cong\frac{2}{5}M_{\bigcirc}R_{\bigcirc}^2\omega_{\bigcirc}=\frac{2}{5}M_{\bigcirc}R_{\bigcirc}^2\frac{2\pi}{T_{\bigcirc}} \tag{12.1.511}$$

   where $M_{\bigcirc}\cong M_{♁}/81$ [kg], $R_{\bigcirc}\cong R_{♁}\cdot 0.272$ [m].

3. The angular momentum of rotation of the Moon around the Earth $\vec{b}_{M-E}$ is perpendicular to the plane of the lunar orbit. In intensity it is (assuming the Moon as punctual otherwise she should apply the Steiner theorem):

   $$\vec{b}=\vec{r}\times\vec{p}\Rightarrow b'=rM_{\bigcirc}v_{\bigcirc} \tag{12.1.512}$$

   where r is the Earth-Moon distance and $v_{\bigcirc}$ the speed of the moon on its orbit.

   Here comes another approximation to simplify the calculation. The elliptical orbit of the Moon has actually an eccentricity of 0.055. We will liken it to a circle for which we will still use Kepler's third law. Then if one notes ω the pulsation and D the semi-major axis one has:

   $$v=D\omega=r\omega \tag{12.1.513}$$

therefore:

$$b' = DM_{\bigcirc}v_{\bigcirc} = D^2 M_{\bigcirc}\omega_{\bigcirc} \tag{12.1.514}$$

Following third Kepler's law (see page 5242) given for recall by:

$$\frac{R^3}{T^2} = \frac{Gm}{4\pi^2} \Rightarrow R^3\omega^2 = Gm \tag{12.1.515}$$

Therefore:

$$D^3\omega^2 = GM_{\text{♁}} \Leftrightarrow \omega_{\bigcirc} = G^{1/2}M_{\text{♁}}^{1/2}D^{-3/2} \tag{12.1.516}$$

So finally:

$$b' = D^2 M_{\bigcirc}\omega_{\bigcirc} = G^{1/2}M_{\bigcirc}M_{\text{♁}}^{1/2}D^{1/2} \tag{12.1.517}$$

The total angular momentum is therefore worth, in projection on the perpendicular to the plane of the ecliptic:

$$\begin{aligned} b_{\text{tot}} &= b_{\text{♁}} + b_{\bigcirc} + b' \\ &\cong \frac{2}{5}M_{\text{♁}}R_{\text{♁}}^2\frac{2\pi}{T_{\text{♁}}}\cos(23°27') + \frac{2}{5}M_{\bigcirc}R_{\bigcirc}^2\frac{2\pi}{T_{\bigcirc}}\cos(6°) + G^{1/2}M_{\bigcirc}M_{\text{♁}}^{1/2}D^{1/2}\cos(5°) \end{aligned} \tag{12.1.518}$$

Let's identify the factors that change over time. Earth's own pulsation, $\omega_{\text{♁}}$, decreases as the length of the day increases according to all actual experimental evidence; the distance D from the Earth to the Moon increases also according to all actual experimental evidence; on the other hand, we will assume the pulsation $\omega_{\bigcirc}$ to be constant (otherwise the problem is unsolvable and anyway the Moon is negligible in comparison of Earth...).

We therefore write that the variation Δb_{tot} of the total angular momentum is zero:

$$\Delta b_{\text{tot}} \cong \frac{2}{5}M_{\text{♁}}R_{\text{♁}}^2\Delta\omega_{\text{♁}}\cos(23°27') + 0 + \frac{1}{2}G^{1/2}M_{\bigcirc}M_{\text{♁}}^{1/2}D^{-1/2}\Delta D\cos(5°) = 0 \tag{12.1.519}$$

as $\Delta\omega_{\bigcirc} = 0$.

Therefore:

$$\Delta D \cong -\frac{4}{5}G^{-1/2}M_{\bigcirc}^{-1}M_{\text{♁}}^{1/2}R_{\text{♁}}^2\Delta\omega_{\text{♁}}D^{1/2}\cos(23°27')\cos^{-1}(5°) \tag{12.1.520}$$

But $\omega_{\text{♁}} = 2\pi/T_{\text{♁}}$ then $\Delta\omega_{\text{♁}} = -2\pi\Delta T_{\text{♁}}/T_{\text{♁}}^2$. Hence:

$$\Delta D \cong \frac{8\pi}{5}G^{-1/2}M_{\bigcirc}^{-1}M_{\text{♁}}^{1/2}R_{\text{♁}}^2T_{\text{♁}}^{-2}\Delta T_{\text{♁}}D^{1/2}\cos(23°27')\cos^{-1}(5°) \tag{12.1.521}$$

So finally:

$$\Delta D \propto T_{\text{♁}}^{-2}\Delta T_{\text{♁}}D^{1/2} \Rightarrow \Delta D \propto \Delta T_{\text{♁}} \tag{12.1.522}$$

We have achieved what we wanted to demonstrate: slowing down of the Earth's own rotation and moving the Moon away are linked. If the Earth rotation slows down, its angular momentum decreases; since that of the Moon on itself is constant, for the total angular momentum to be conserved, the Moon must move away from the Earth, thus increasing its angular momentum.

Knowing, due to experimental measurements, that $\Delta T \cong 1.64 \cdot 10^{-5}\,[\text{s} \cdot \text{year}^{-1}]$ and that:

$$\begin{aligned} G &\cong 6.67 \cdot 10^{-11}\,[\text{m}^3 \cdot \text{kg}^{-1} \cdot \text{s}^{-2}] & M_{\bigcirc} &\cong 7.34 \cdot 10^{22}\,[\text{kg}] \\ M_{\text{♁}} &\cong 5.97 \cdot 10^{24}\,[\text{kg}] & R_{\text{♁}} &\cong 6371 \cdot 10^{3}\,[\text{m}] \\ D &\cong 3.84 \cdot 10^{8}\,[\text{m}] & T &= 8620\,[\text{s}] \end{aligned} \tag{12.1.523}$$

We get:

$$\Delta D \cong \frac{8\pi}{5} G^{-1/2} M_{\bigcirc}^{-1} M_{\text{♁}}^{1/2} R_{\text{♁}}^{2} T_{\text{♁}}^{-2} \Delta T_{\text{♁}} D^{1/2} \cos(23°27') \cos^{-1}(5°) \cong 3.3 \cdot 10^{-2}\,[\text{m} \cdot \text{year}^{-1}] \tag{12.1.524}$$

Hence $3.3\,[\text{cm} \cdot \text{year}^{-1}]$ (the measured value is actually of $3\,[\text{cm} \cdot \text{year}^{-1}]$).

Geologists have found sedimentary rocks (like the Elatina Formation in Australia) that preserve daily and monthly tidal layers from 600 millions to 2.5 billion years ago. These "fossilised tides" allow scientists to calculate exactly how fast the Moon was moving back then. These geolocial records show that 600 million years ago, the recession rate was only about $2.17\,[\text{cm} \cdot textyear]$ (see [**âĂć**]), nearly half of today's rate. If we do the maths we can check easily that the Moon was much closer in the past, but it remained well outside the Roche limit (see page 5337) throughout the timeline of life on Earth.

Where are we going ? 300 million years ago, the day lasted 22 hours, there were 400 days in the year. When the Earth-Moon coupling will be over, the day will last 50 hours of our current days. A simple rule of three can say that it will be roughly in 250 billion years. The Moon will then be at a distance of 1, 500 terrestrial radius, compared to the 60 today (the distance of the Earth to the Sun is worth 25, 000 terrestrial rays). For sure there will be also no Solar eclipse anymore in the future as we know them actually!

Remark

For information, the rotation of Earth's on itself slows down at the day we write these lines of approximately 2.3 milliseconds per century. That means 1 hour every 180 millions years. Each year the Earth's orbit speed around the Sun (actually a G2V-type star, aka yellow dwarf) also slows down of approximately 3 nanometers-per-second. Using Kepler's law, that means that the Earth approaches the Sun of 3 micrometers per 1 billion year......!!!!

But all this is only a bold extrapolation, because long before these 250 billion years, the Sun will have become a red giant (in 5 billion years) and its crown will have reached the Earth ...

12.1.8 Trigonometric parallax

Measuring distances to objects within our Galaxy is not always a straightforward task – we cannot simply stretch out a measuring tape between two objects and read off the distance. Instead, a number of techniques have been developed that enable us to measure distances to stars without needing to leave the Solar System. One such method is "trigonometric parallax", which depends on the apparent motion of nearby stars compared to more distant stars, using observations made 6 months apart (corresponding to the measurement of diameter of the apparent approximated circular motion they have in the sky).

A nearby object viewed from two different positions will appear to move with respect to a more distant background. This change is named a "parallax". A simple demonstration is to hold your finger up in front of your face and look at it with your left eye closed and then your right eye. The position of your finger will appear move compared to more distant objects.

By measuring the amount of the shift of the object's position (relative to a fixed background, such as the very distant stars) with observations made from the ends of a known baseline, the distance to the object can be calculated.

The trigonometric parallax method is very simple (but difficult to implement on the surface of our planet for very distant stars). Any amateur astronomer observed the flight of the star it observes with his eye. This movement is named as we have just seen the "diurnal movement" It is due to the rotation of the Earth itself. The star is also driven in an elliptical motion much less easily detectable: the "parallactic motion".

It is due, as suggested in the figure below, to the rotation of the Earth around the Sun. So we measure the angle p and we have obviously:

$$\frac{a}{d}=\tan(p) \tag{12.1.525}$$

If the angle is small (which is very often the case given the distance of stars...) we can take the first term of the Taylor expansion (see section Sequences and Series page 1703) of the tangent function:

$$\tan(p)=p+\frac{p^3}{3}+\frac{2p^5}{15}+\ldots\cong p \tag{12.1.526}$$

Which allow us to write:

$$\boxed{d\cong\frac{a}{p}} \tag{12.1.527}$$

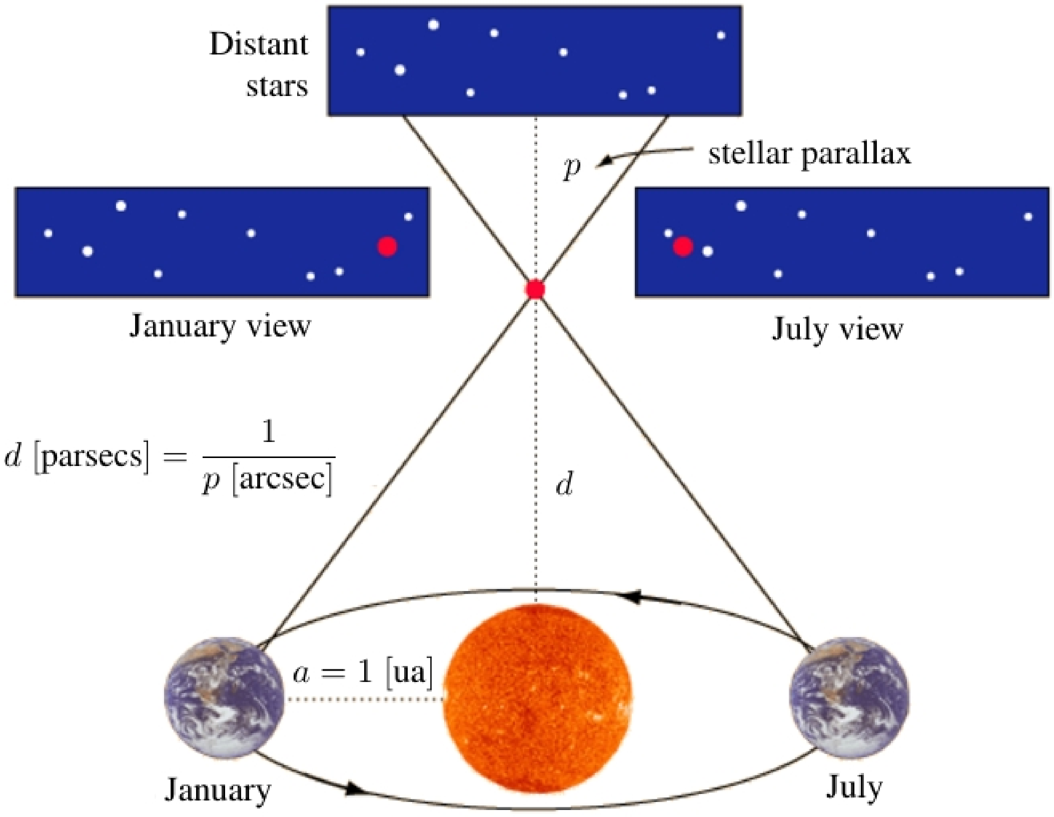

Figure 12.63: **Trigonometric parallax principle**

If the parallax angle, p is measured in arc-seconds (arcsec), then the distance to the star, d in parsecs (pc) is given by:

$$d \cong \frac{1}{p} \qquad (12.1.528)$$

It is important to notice that in this example we assume that both the Sun (actually a G2V-type star, aka yellow dwarf) and star are not moving with a transverse velocity with respect to each other. If they were this would complicate the picture as presented here. In practice stars with significant proper motions require at least three epochs of observation to accurately separate their proper motions from their parallax. Stars that are members of binaries further complicate the picture.

For example, we often see sources that say a parallax is found from measurements taken six months apart. That is rarely the case, and if you think about it, not all stars are visible in the night sky six months apart (from the same location on Earth). In fact a parallax measurement will consist of a series of measurements, possibly taken over more than 1 year. There is no formal requirement for any particular measurement interval, though of course the biggest parallax signal would be if we could get measurements six months apart.

In addition to parallax, we need to account for the "proper motion" of the star across the sky. To a first order approximation this is a linear change in right ascension (the celestial equivalent of longitude, measuring the East-West position of an astronomical object on the celestial sphere) and declination (angular distance of a celestial body North (+) or South (−) from the celestial equator) with time (though more complicated models can be used, and you have to account for the ellipticity of the Earth's orbit too). The position of the star in question (with respect to distant background stars) measured in multiple images at multiple times would then be fitted with a function that results in a determination of the parallax and the proper motions in both coordinates. Any motion of the "background stars" is compensated by averaging over all the faint stars in the field. They will all move in a systematic way due to the motion of the Sun in the Galaxy (this is part of the "proper motion"), but their random motions (if they are distant) will be very small and average out well.

A perfect visualisation is provided by Hubble Space Telescope images of Proxima Centauri which show its path across they sky and illustrates the cyclical motion due to parallax and the linear motion across the sky caused by its proper motion.

The motion of the star towards or away from the Sun could be accounted for from the measurement of the star's line of sight velocity. In practice, these motions are of order tens of km/s and this means it would take tens of thousands of years to change the distance by one light year.

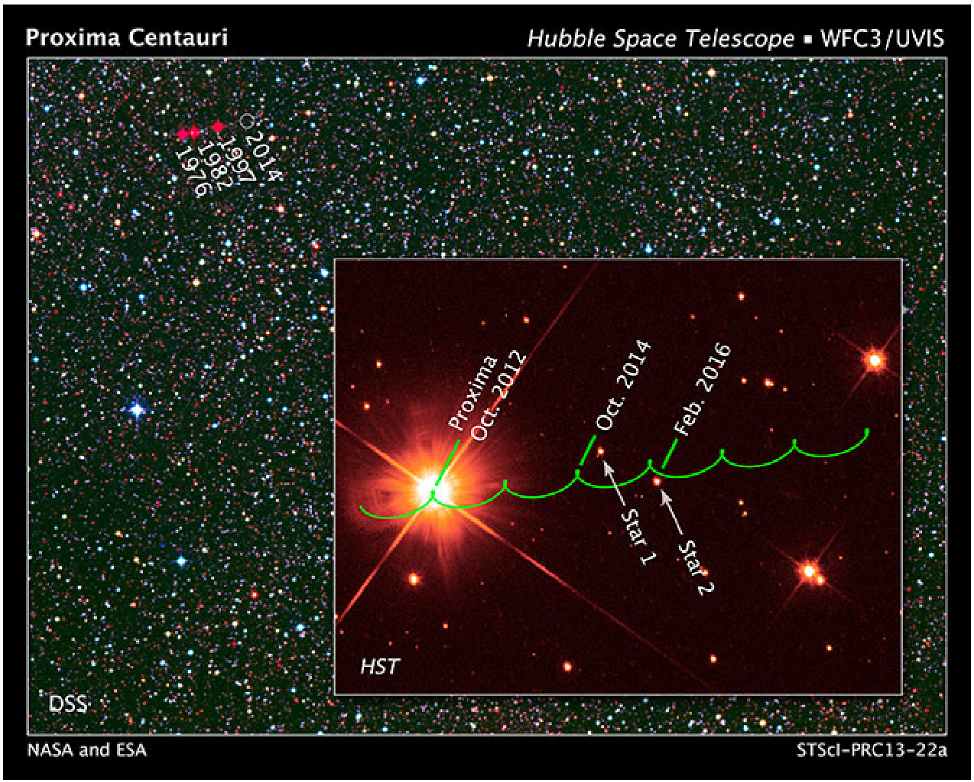

Figure 12.64: **Hubble space telescope Proxima Centauri tracking**

The only star with a parallax greater than 1 [arcsec] as seen from the Earth is the Sun - all other known stars are at distances greater than 1 [pc] and parallax angles less than 1 [arcsec] ($1/3600$ of degree... we understand better why this what impossible to measure before the 119th century). When measuring the parallax of a star, it is important to "account for the star's proper motion, and the parallax of any of the fixed" stars used as references.

Over a 4 year period from 11989 to 11993, the Hipparcos Space Astrometry Mission measured the trigonometric parallax of nearly $120,000$ stars with an accuracy of 0.002 [arcsec]. The GAIA mission, to be launched in 12010 (holocene calendar), will be able to measure parallaxes to an accuracy of 10^{-6} [arcsec], allowing distances to be determined for more than 200 million stars.

Remark

Stellar parallax is so difficult to detect that its existence was the subject of much debate in astronomy for hundreds of years. Thomas Henderson, Friedrich Georg Wilhelm von Struve, and Friedrich Bessel made first successful parallax measurements in 11832-11838 (holocene calendar), for the stars Alpha Centauri, Vega, and 61 Cygni.

In practice when we measure the parallax we must obviously take in account the obliquity of Earth on it's orbit that is in this beginning of the 121st century (holocene calendar) equal to $23°26'13.3$ otherwise me may think that stars have a huge parallax and are therefore at a small distance of us as illustrated by the figure below:

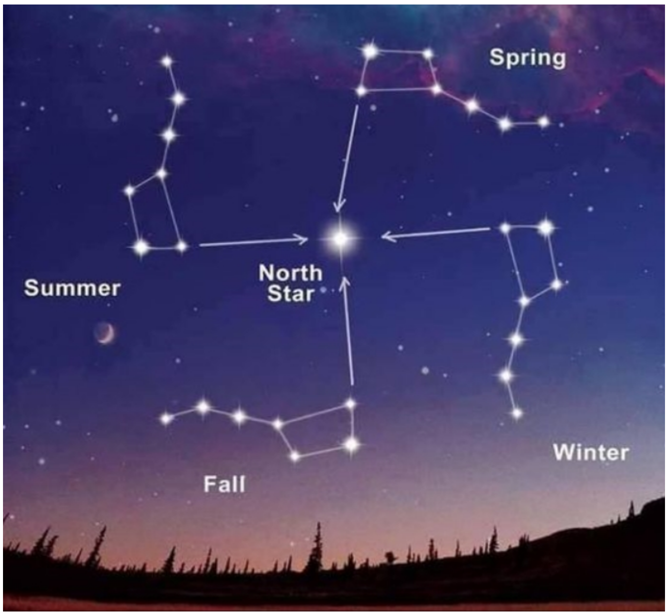

Figure 12.65: **Shift angle of the Big Dipper that seems huge if we do not subtract the obliquity angle**

In the figure above the "North star" may be any fixed star close to either celestial pole of any given planetary body (actually approximately Polaris that is 0.736 degrees away from exact North). It might refer to any such star in the Earths remote history or future, situated along the path of the celestial poles in the course of the procession of the Earth's axis.

The identity of the pole stars gradually changes over time because the celestial poles exhibit a slow continuous drift through the star field. The primary reason for this is the precession of the Earth's rotational axis, which causes its orientation to change over time. Precession causes the celestial poles to trace out circles on the celestial sphere approximately once every $26,000$ years, passing close to different stars at different times (with an additional slight shift due to the proper motion of the stars).

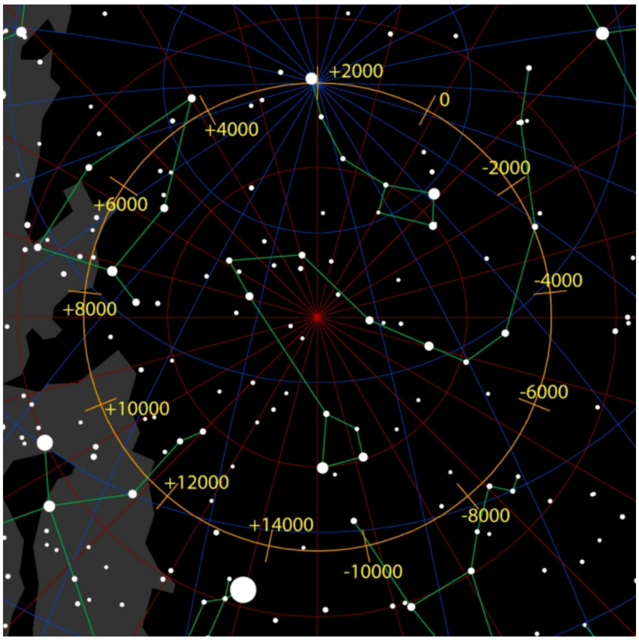

Figure 12.66: **The path of the north celestial pole amongst the stars due to the effect of precession, with dates shown (source: Wikipedia)**

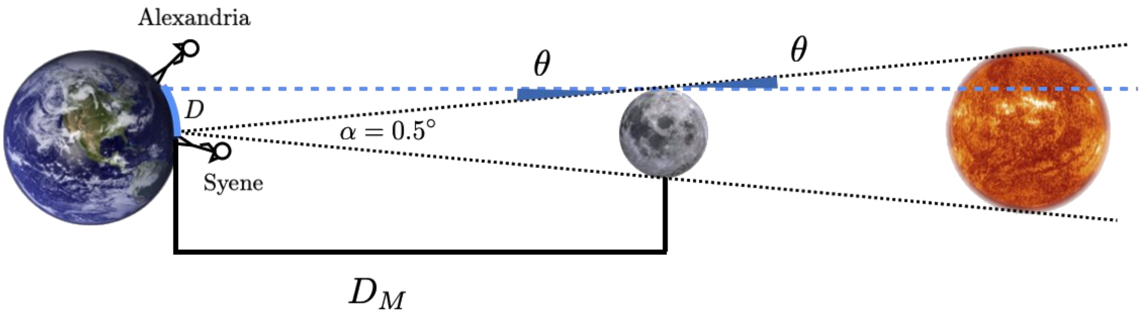
Remark

There are some situations in which we can't measure the distance to a single star of some particular spectral type directly because all the stars of that type are just too far away. In these situations, we can fall back upon two techniques which deal with groups of nearly identical stars: statistical parallax and secular parallax.

Notice that the same type of trigonometric technique seems to have been used by Hipparchus to determine the distance to the Moon in 9871 (holocene calendar):



At the time of the total eclipse of the Sun an observer in Alexandria saw $1/5$ of the Sun ($\theta = \alpha/5 = 0.1°$). For small θ $\sin\theta \approx \theta = D/D_M$

This image below shows a subset of stars in by ESA Gaia's second data release (that can be downloaded here `https://cdn.gea.esac.esa.int/Gaia/`) between July 12014 to May 12016 (holocene calendar) with reasonably small parallax errors (less than 12.5% for most stars, and less than 50% for the brightest stars) and exaggerated $10,000$ times for pedagogical reasons to be visible to the human eye on a picture.

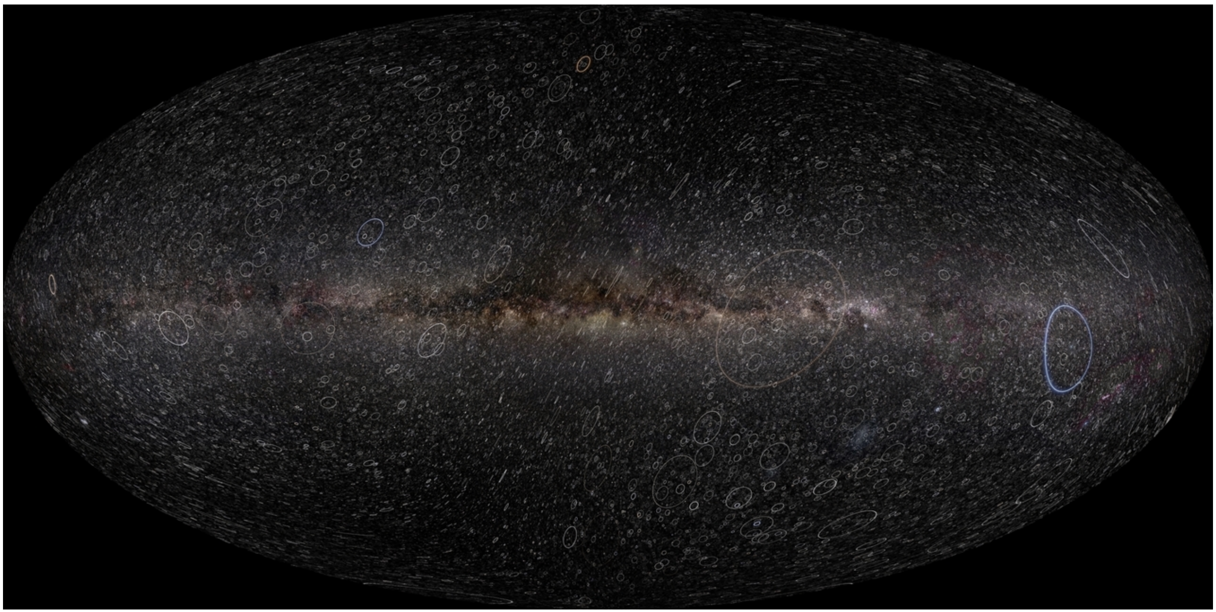


Figure 12.67: **Parallax motion seen by Gaia, exaggerated 10,000 times (credits: ESA/Gaia/DPAC, CC BY-SA 3.0 IGO. Acknowledgement: Produced by Jos de Bruijne)**

The bright horizontal structure visible at the centre of the image is the Galactic plane, the flattened disc that hosts most of the stars in our home Galaxy. The positions of stars are shown in the Galactic coordinate system.

12.1.9 Planets' Motion

On January 7, 11610 (holocene calendar), Galileo made observations of Jupiter and discovered four of the giant planet's satellites, now named after him as the "Galilean moons" (Ganymede, Callisto, Europa, and Io). They were heavenly bodies that clearly orbited an entity other than the Earth, as Galileo concluded over several nights of observation, seeing the moons change sides as they travelled around the planet. This discovery clearly contradicted the Catholic Church's Ptolemaic belief (and also various statements of the Quran - who by the way as the Bible - doesn't contain any Science but only poor value claims) that every celestial body orbits the Earth.

But the coup de grâce came within eight months, in September of 11610 (holocene calendar), when Galileo observed the planet Venus and noted that it went through complete phases, like our Moon. According to the Ptolemaic model, built on epicycles, we should only be able to see some of Venus's phases: either thin crescents (if it were on the inside of the orbit of the Sun around the Earth) or only gibbous and full phases (if it were on the outside of the Sun's orbit) - but not both. The fact that all phases of Venus are visible, just as we see with our Moon, meant to Galileo that the Ptolemaic model couldn't possibly be right. Rather, Copernicus's model of the Solar System was the one that reflected reality[17]. the Tuscan rulers could not protect Galileo from an order of extradition to face the dreaded Inquisition in Rome - which had already put to death many independent thinkers for ideas contrary to the official Catholic understanding of the universe... Although Pope Urban VIII was sympathetic to him, even the pope could not deter the Inquisition in its persecution of Galileo. The infamous trial took place in February 1633 (holocene calendar). Under threat of torture, Galileo publicly recanted his heliocentric heresy and was confined for the rest of his days to house arrest in his villa at Arcetri, outside Florence. Galileo's trial, more than any other event in history, has come to symbolize the sharp split between science and faith, a conflict that continues to rage in our own time as science still continue to debunk irrational and illogic beliefs from various religions.

---

[17] In reality the first one to make the assumption of heliocentric system seems to be the greek Aristarchus of Samos almost 1600 years before Copernicus (see [563])!

We will briefly turn our attention to the movements of the planets in ideal and situations simplified in the point of view on an observer on Earth. We consider that all the movements will be in the same plane (coplanar) perfectly circular and constant...

Definition (#12.1.527): The planets that are closer to the Sun than the Earth (whose radius is less than one astronomical unit AU[18]), that is to say the planets Mercury and Venus are "inferior planets", the other planets (Mars and beyond) are named the "outer planets".

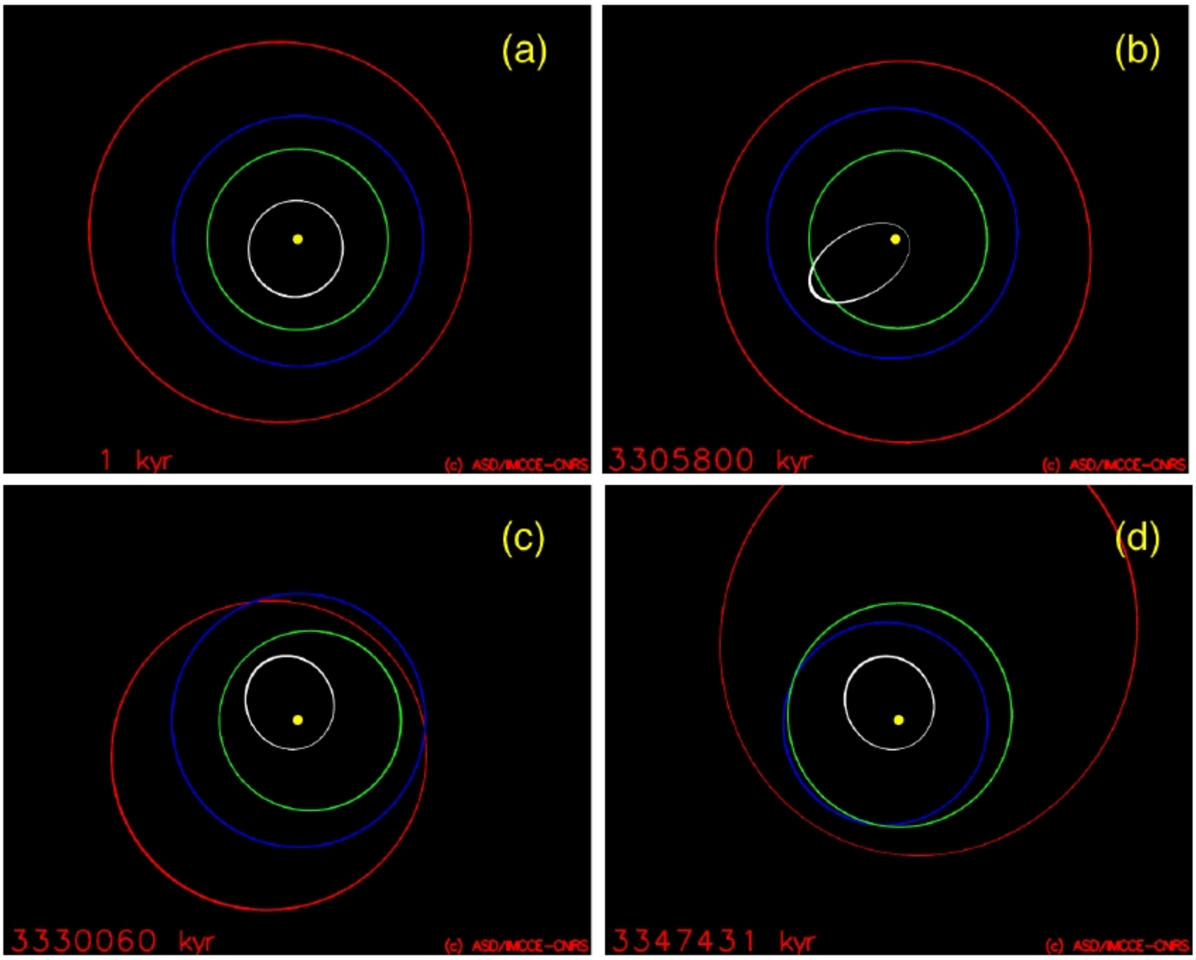

Figure 12.68: At the opposite of the myth, our Earth is far to be perfect (huge climate variations, orbiting and non-eternal star, colliding regularly with extinction level asteroids, etc.) and on a stable orbit. As shown in the computer simulations of Laskar and Gastineau [338], it may collide in the future with Venus (Mercury in white, Venus in green, Earth in blue, Mars in red).

---

[18] Defined as an average of $149,597,870,700$ [m] ((about 150 million kilometres). In ISO 80000-3, the symbol of the astronomical unit is "ua".

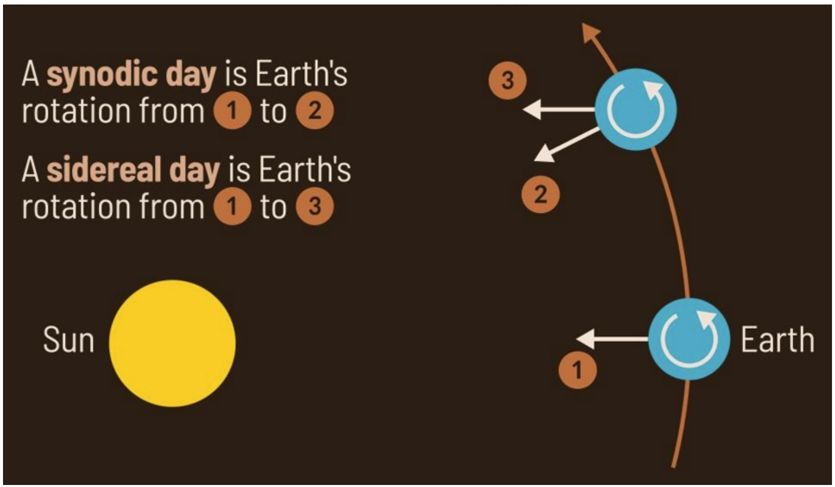
12.1.9.1 Synodic and Sidereal period

One of the many tools used in Astronomy are the formulas used to determine orbital motions. There are two basic forms of orbit periods:

- Sidereal Period
- Synodic Period

A "sidereal period" is an actual measure of a complete orbit relative to the stars (since the stars are unmoving - or at least moving very slowly). A "synodic period" is a rotation of a planet so that it appears to be in the same place in the night sky.

The synodic period of a planet (or satellite) is the time needed by this planet to return to the same configuration Earth-Planet-Sun (if we consider this particular case), that is to say in the same place in the sky relatively to the Sun, as seen from Earth. This period differs from the sidereal rotation period of the planet because the Earth itself moves around the Sun. Accordingly, it is the period of apparent revolution, the duration between two conjunctions Planet-Sun as viewed from Earth.



A **synodic day** is Earth's rotation from ① to ②
A **sidereal day** is Earth's rotation from ① to ③
3
2
1
Sun
Earth

Figure 12.69: **Synodic vs Sidereal day**

The term generally refers to the time between two identical aspects of the object (opposition, conjunction, etc.) and thus depends on the three bodies involved.

The "sidereal day" is the time Earth takes to rotate for a distant star to return to the same position in the sky, whereas a "solar day" is the time for the Sun to return to the same position.

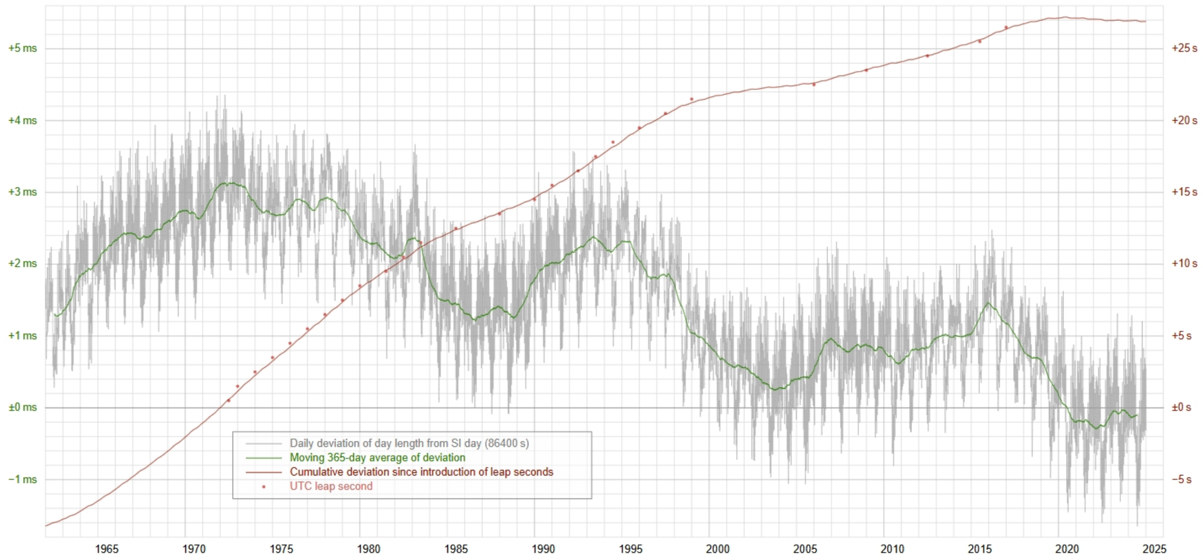


Figure 12.70: **Deviation of day length from SI-based day (86,400 s) 11962–12022: daily, moving 365-day average and cumulative (data source: International Earth rotation and Reference systems Service (IERS))**

A year has actually around 365.25 solar days, but 366.25 sidereal days to account for one revolution around the Sun. As a solar day has 24 hours, a sidereal day has around:

$$\frac{365.25}{366.25}\cdot 24\,[\text{hours}]=23\,[\text{hours}],56\,[\text{minutes}]\text{ and }4.1\,[\text{seconds}] \tag{12.1.529}$$

To mathematically study the problem in question, let us consider the following diagram with two planets describing a perfectly circular orbit at a constant angular velocity and in the same plane and in the same direction and where we have $\omega_1>\omega_2$ (thus the inner planet is faster than the outer planet):

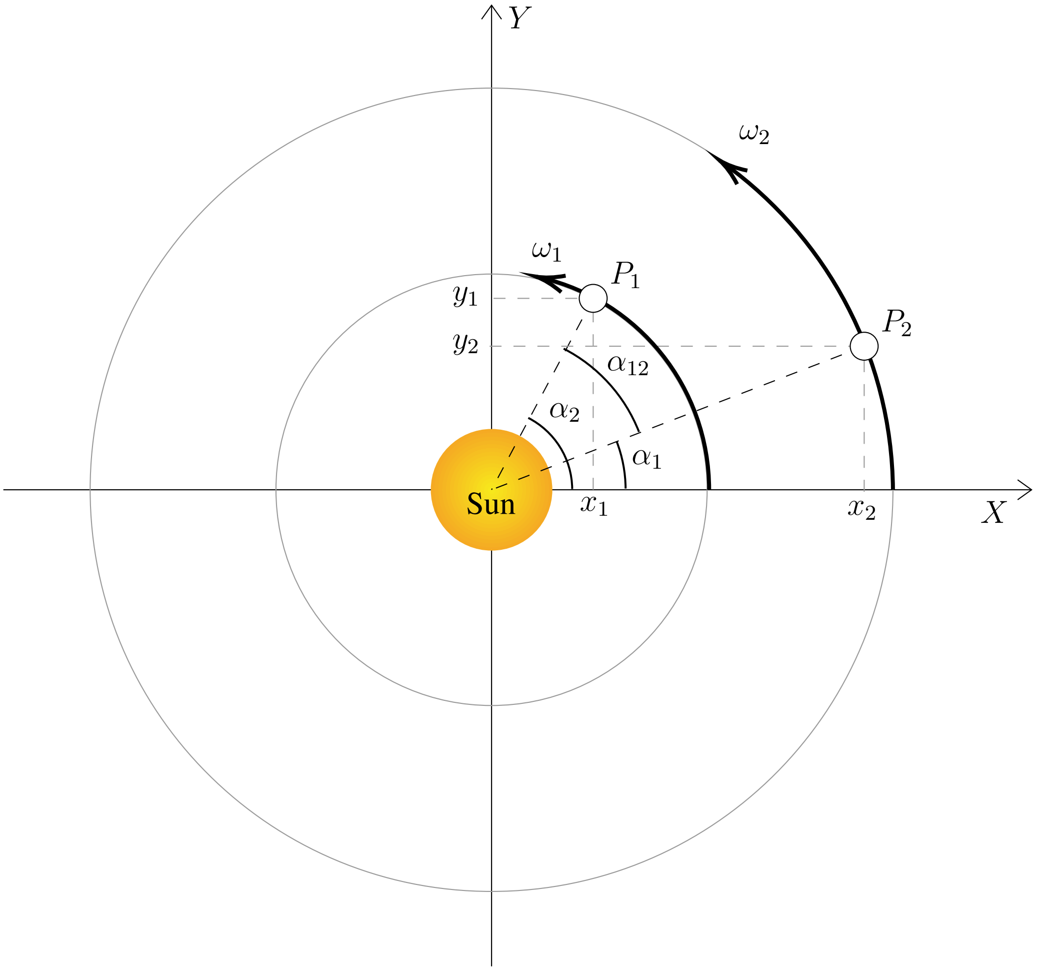

Figure 12.71: **Basic scheme for determining the synodical period**

where P_1 and P_2 are two planets which we will denote the respective sidereal periods by T_1, T_2 and for which we deduce the angular velocities:

$$\omega_1 = \frac{2\pi}{T_1} \qquad \omega_2 = \frac{2\pi}{T_2} \tag{12.1.530}$$

If we take as zero time, the time when the two planets are both aligned with the X axis and at the same side of this axis (so in "inferior conjunction"), then the angle between this axis and each of the planets is:

$$\alpha_1 = \omega_1 t \qquad \alpha_1 = \omega_2 t \tag{12.1.531}$$

We have respectively:

$$\alpha_{12} = \alpha_1 - \alpha_2 = (\omega_1 - \omega_2)t = \omega_{12} t \tag{12.1.532}$$

We seek therefore all the instants t where the following relation is satisfied for a fixed α_{12}:

$$\alpha_{12} = \omega_{12} t \tag{12.1.533}$$

Therefore it comes:

$$T = \frac{\alpha_{12}}{\omega_{12}} = \frac{\alpha_{12}}{\dfrac{2\pi}{T_1} - \dfrac{2\pi}{T_2}} = \frac{T_1 T_2 \alpha_{12}}{2\pi(T_2 - T_1)} \tag{12.1.534}$$

If we look from time zero the first (next) conjunction ("superior conjunction"), this is equivalent to put that $\alpha_{12} = \pi$ and therefore that:

$$T = \frac{T_1 T_2}{2(T_2 - T_1)} \tag{12.1.535}$$

If we look from time zero the first (next) conjunction ("inferior conjunction"), this is equivalent to put that $\alpha_{12} = 2\pi$ and therefore that:

$$\boxed{T = \frac{T_1 T_2}{T_2 - T_1}} \tag{12.1.536}$$

In the case where $\omega_2 > \omega_1$ (typically Earth and one of its outer planets), the same reasoning leads us to:

$$T = \frac{T_1 T_2}{T_2 - T_1} \tag{12.1.537}$$

Here are some actuals synodic and sidereal years of the Solar System relatively to Earth:

Planet	Synodic period [d]	Sidereal period [d]
Mercury	115.878	87.969
Venus	583.921	224.709
Mars	779.964	686.960
Jupiter	398.861	4,335.355
Saturn	378.094	10,757.737
Uranus	369.654	30,708.160
Neptune	367.486	60,224.904

Table 12.14: **Various synodic and sidereal periods**

As we can see from this table, we can make some empirical observations:

1. For the inner planets: The closer we get to the Sun, the more the synodical period is short, indeed in the proved relation above, the more T_1 is small more T decreases. So if there was a rotating planet very near the Sun, both sidereal and synodic periods are substantially equal.

2. When we approach the Earth, the period increases. If there was a planet near to Earth, we would then have T_1 value close to T_2 value and the synodical period would be very large.

3. For the outer planets: The synodic period decreases when the planet is farther from the Earth and approaches terrestrial sidereal period of 365 days. We see well for Neptune, if we discovered a planet even further its synodic period would approach even more the 365 days.

In reality we can define other periods that the synodic or sidereal period, like for example for Earth's Moon:

Type of Period for the Moon	**Value**
Synodic Month	29.530589 days = 29 days 12 h. 44 min. 3 sec.
Sidereal Month	27.321662 days = 27 days 7 h. 43 min. 12 sec.
Anomalistic Month (perigee to perigee)	27.554550 days = 27 days 13 h. 18 min. 33 sec.
Draconic Month (node to node)	27.212221 days = 27 days 5 h. 5 min. 36 sec.

Here is another illustration of the concept taken from Wikipedia (author: Xaonon) that is very good to understand the concept if it may help:

12.1.9.2 Planet's apparent retrograde motion

The "retrograde motion" of a planet is an apparent motion of this planet which gives the impression that it stop in his path in the "direct movement" to start reversing. This phenomenon is the result of the difference between the revolution speed of the planet and the Earth around the Sun.

The example below shows roughly what a terrestrial observer (blue discs) can be observed by monitoring month after month, the apparent motion of Mars (brown discs):

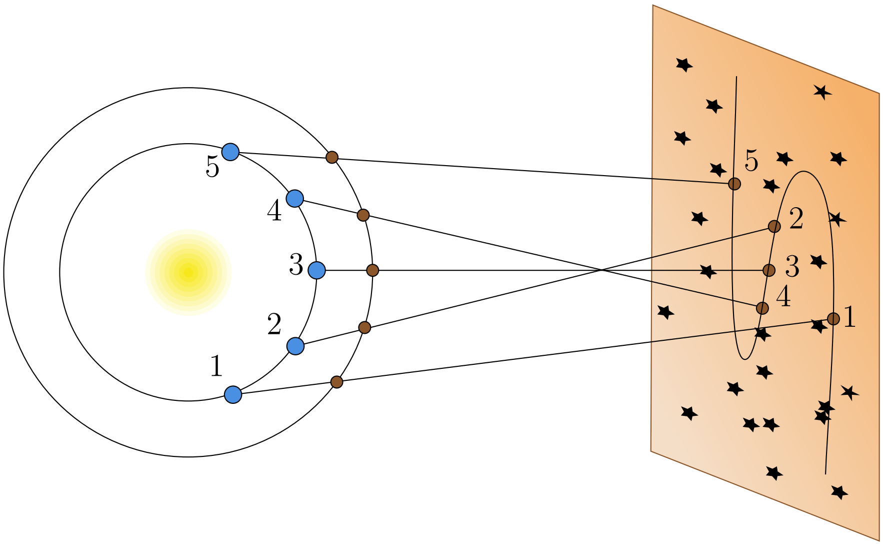

Figure 12.72: **Retrograde motion principle (source: Wikipedia)**

Or more explicitly (in the legend of the figure below, the years are given based on the holocene calendar):

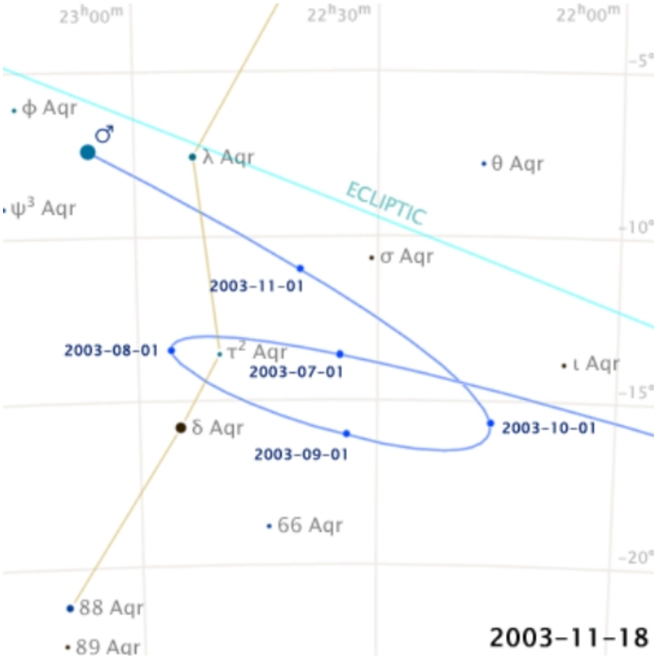

Figure 12.73: **Apparent retrograde motion of Mars in 12003 as seen from Earth (source: Wikipedia, author: Eugene Alvin Villar)**

To study this phenomenon mathematically, we will consider the following figure:

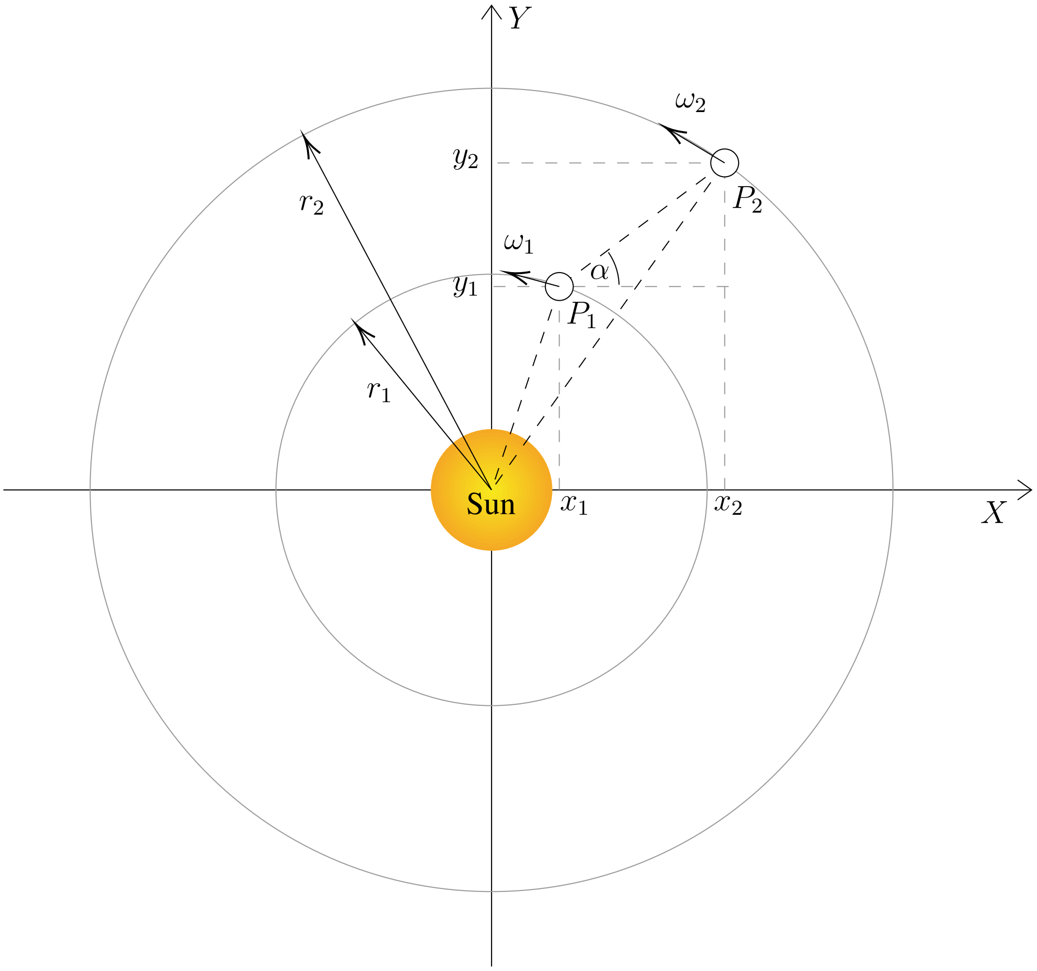

Figure 12.74: Basic scheme for the study of planet's retrograde motion

with two planets describing a perfectly circular orbit at a constant angular velocity and in the same plane and in the same direction and where we have. It is clear that the inner planet will therefore caught up the outer planet and it will seem to have a retrograde motion as shown in the figure below:

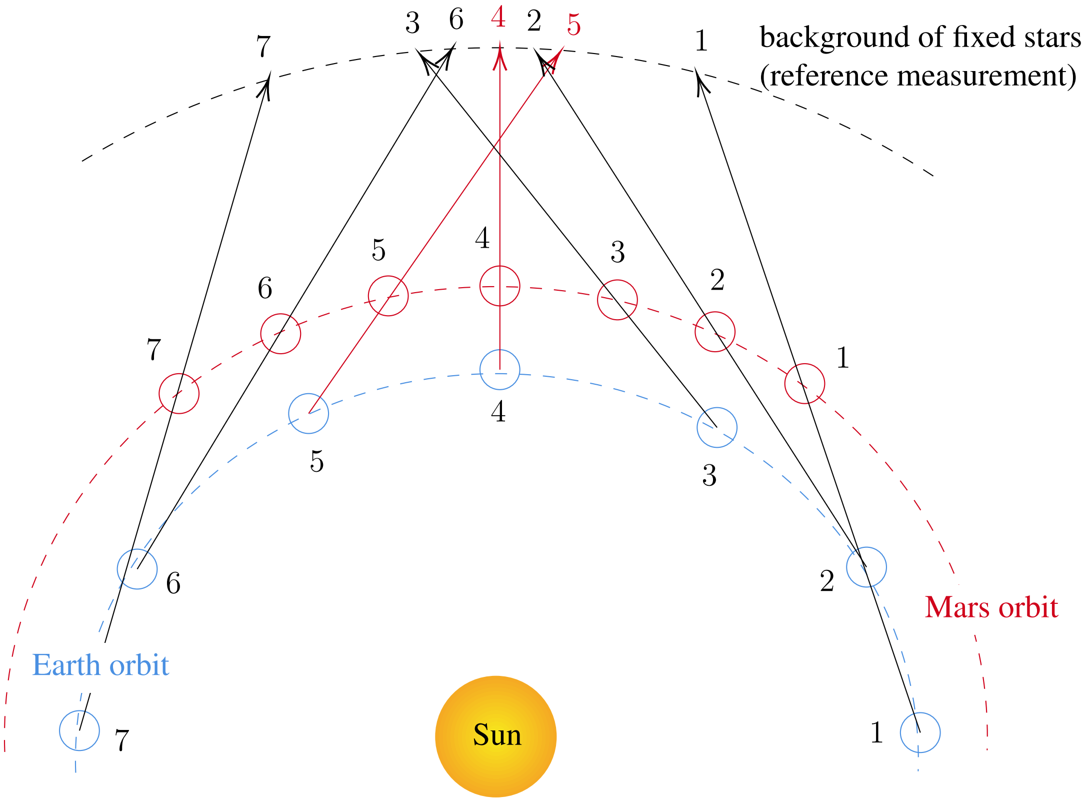

Figure 12.75: **Figure to illustrate the choice of zero time**

As the reader can check it in the figure above we see that the retrograde motion with respect to the fixed stars begins when the angle between the two planets is zero and it ends when the angle between the two planets pass through a maximum.

Therefore, in the prior previous figure, we have:

$$\tan(\alpha)=\frac{y_2-y_1}{x_2-x_1}=\frac{r_2\sin(\omega_2 t)-r_1\sin(\omega_1 t)}{r_2\cos(\omega_2 t)-r_1\cos(\omega_1 t)} \quad (12.1.538)$$

So to know the time between when the moment where the angle is zero between the two planets, reaches a maximum and decreases again, we simply need determine when occurs the sign of change in the previous function. To do this we just search when the derivative is zero:

$$\frac{\mathrm{d}}{\mathrm{d}t}\left(\frac{r_2\sin(\omega_2 t)-r_1\sin(\omega_1 t)}{r_2\cos(\omega_2 t)-r_1\cos(\omega_1 t)}\right)=0 \quad (12.1.539)$$

By applying the derivation rules seen in the section of Differential and Integral Calculus:

$$\begin{aligned}
&\frac{\mathrm{d}}{\mathrm{d}t}\left([r_2\sin(\omega_2 t)-r_1\sin(\omega_1 t)]\frac{1}{r_2\cos(\omega_2 t)-r_1\cos(\omega_1 t)}\right)\\
&=r_2\omega_2\cos(\omega_2 t)-r_1\omega_1\cos(\omega_1 t)\frac{1}{r_2\cos(\omega_2 t)-r_1\cos(\omega_1 t)}\\
&-\frac{r_2\sin(\omega_2 t)-r_1\sin(\omega_1 t)}{(r_2\cos(\omega_2 t)-r_1\cos(\omega_1 t))^2}(-r_2\omega_2\sin(\omega_2 t)+r_1\omega_1\sin(\omega_1 t))\\
&=\frac{(r_2\omega_2\cos(\omega_2 t)-r_1\omega_1\cos(\omega_1 t)(r_2\cos(\omega_2 t)-r_1\cos(\omega_1 t))}{(r_2\cos(\omega_2 t)-r_1\cos(\omega_1 t))^2}\\
&-\frac{(r_2\sin(\omega_2 t)-r_1\sin(\omega_1 t))(-r_2\omega_2\sin(\omega_2 t)+r_1\omega_1\sin(\omega_1 t))}{(r_2\cos(\omega_2 t)-r_1\cos(\omega_1 t))^2}=0
\end{aligned} \quad (12.1.540)$$

Hence after simplification:

$$\begin{aligned}&(r_2\omega_2\cos(\omega_2 t)-r_1\omega_1\cos(\omega_1 t))(r_2\cos(\omega_2 t)-r_1\cos(\omega_1 t))\\&-(r_2\sin(\omega_2 t)-r_1\sin(\omega_1 t))(-r_2\omega_2\sin(\omega_2 t)+r_1\omega_1\sin(\omega_1 t))=0\end{aligned}\tag{12.1.541}$$

We develop all this:

$$\begin{aligned}&r_2^2\omega_2\cos^2(\omega_2 t)-r_2r_1\cos(\omega_2 t)\cos(\omega_1 t)-r_1r_2\cos(\omega_1 t)\cos(\omega_2 t)+r_1^2\omega_1\cos^2(\omega_1 t)\\&+r_2^2\omega_2\sin^2(\omega_2 t)-r_2r_1\omega_1\sin(\omega_2 t)\sin(\omega_1 t)-r_1r_2\omega_2\sin(\omega_1 t)\sin(\omega_2 t)+r_1^2\omega_1\sin^2(\omega_1 t)=0\end{aligned}\tag{12.1.542}$$

and we simplify a first time:

$$\begin{aligned}&r_2^2\omega_2-r_2r_1\omega_2\cos(\omega_2 t)\cos(\omega_1 t)-r_1r_2\omega_1\cos(\omega_1 t)\cos(\omega_2 t)+r_1^2\omega_1\\&-r_2r_1\omega_1\sin(\omega_2 t)\sin(\omega_1 t)-r_1r_2\omega_2\sin(\omega_1 t)\sin(\omega_2 t)=0\end{aligned}\tag{12.1.543}$$

and second:

$$r_2^2\omega_2+r_1^2\omega_1-r_1r_2\begin{bmatrix}\omega_2\cos(\omega_2 t)\cos(\omega_1 t)+\omega_1\cos(\omega_1 t)\cos(\omega_2 t)\\+\omega_1\sin(\omega_2 t)\sin(\omega_1 t)+\omega_2\sin(\omega_1 t)\sin(\omega_2 t)\end{bmatrix}=0\tag{12.1.544}$$

and finally a third one:

$$r_2^2\omega_2+r_1^2\omega_1-r_1r_2(\omega_1+\omega_2)[\cos(\omega_1 t)\cos(\omega_2 t)+\sin(\omega_1 t)\sin(\omega_2 t)]=0\tag{12.1.545}$$

and after rearrangement:

$$r_2^2\omega_2+r_1^2\omega_1=r_1r_2(\omega_1+\omega_2)[\cos(\omega_1 t)\cos(\omega_2 t)+\sin(\omega_1 t)\sin(\omega_2 t)]\tag{12.1.546}$$

We simplify using trigonometric identities proved in the section Trigonometry:

$$r_2^2\omega_2+r_1^2\omega_1=r_1r_2(\omega_1+\omega_2)\cos((\omega_1-\omega_2)t)\tag{12.1.547}$$

The values of t that satisfy this relation gives us the sign change we were looking for.

If t_0 is the first value of t that satisfies the equation, we have:

$$\cos((\omega_1-\omega_2)t)=\frac{r_2^2\omega_2+r_1^2\omega_1}{r_1r_2(\omega_1+\omega_2)}\tag{12.1.548}$$

The next value of t will be such that:

$$(\omega_1-\omega_2)t_1=2\pi\pm(\omega_1-\omega_2)t_0\tag{12.1.549}$$

and therefore:

$$t_1=\frac{2\pi}{\omega_1-\omega_2}\pm t_0\tag{12.1.550}$$

If we introduce the rotation periods, we have:

$$t_1=\frac{T_1T_2}{T_2-T_1}\pm t_0\tag{12.1.551}$$

To come back to:

$$\cos((\omega_1-\omega_2)t_0)=\frac{r_2^2\omega_2+r_1^2\omega_1}{r_1r_2(\omega_1+\omega_2)} \tag{12.1.552}$$

it may be more convenient to write it in the traditional following form:

$$\begin{aligned}\cos\left(2\pi\frac{T_2-T_1}{T_2T_1}t_0\right)&=\frac{r_2^2\dfrac{2\pi}{T_2}+r_1^2\dfrac{2\pi}{T_1}}{r_1r_2\left(\dfrac{2\pi}{T_1}+\dfrac{2\pi}{T_2}\right)}=\frac{r_2^2\dfrac{1}{T_2}+r_1^2\dfrac{1}{T_1}}{r_1r_2\left(\dfrac{1}{T_1}+\dfrac{1}{T_2}\right)}=\frac{r_2^2\dfrac{T_1}{T_2T_1}+r_1^2\dfrac{T_2}{T_1T_2}}{r_1r_2\left(\dfrac{T_1+T_2}{T_1T_2}\right)}\\&=\frac{\dfrac{r_2^2T_1+r_1^2T_2}{T_1T_2}}{r_1r_2\left(\dfrac{T_1+T_2}{T_1T_2}\right)}=\frac{r_2^2T_1+r_1^2T_2}{r_1r_2(T_1+T_2)}\end{aligned} \tag{12.1.553}$$

So far, we have only do geometry. No law of gravitation intervened in the calculations. As the radius are unknown or little known (at least historically), we will use the Kepler's third law (periods law) that is for recall:

$$T^2=c^{te}D^3 \tag{12.1.554}$$

where for recall D is the semi-major axis of the orbit, and if it is circular, it becomes a simple radius. So we have:

$$r=\frac{T^{2/3}}{\sqrt{c^{te}}} \tag{12.1.555}$$

Therefore:

$$\cos\left(2\pi\frac{T_2-T_1}{T_2T_1}t_0\right)=\frac{r_2^2T_1+r_1^2T_2}{r_1r_2(T_1+T_2)}=\frac{\dfrac{T_2^{4/3}}{c^{te}}T_1+\dfrac{T_1^{4/3}}{c^{te}}T_2}{\dfrac{T_1^{2/3}}{\sqrt{c^{te}}}\dfrac{T_2^{2/3}}{\sqrt{c^{te}}}(T_1+T_2)}=\frac{T_2^{4/3}T_1+T_1^{4/3}T_2}{T_1^{2/3}T_2^{2/3}(T_1+T_2)} \tag{12.1.556}$$

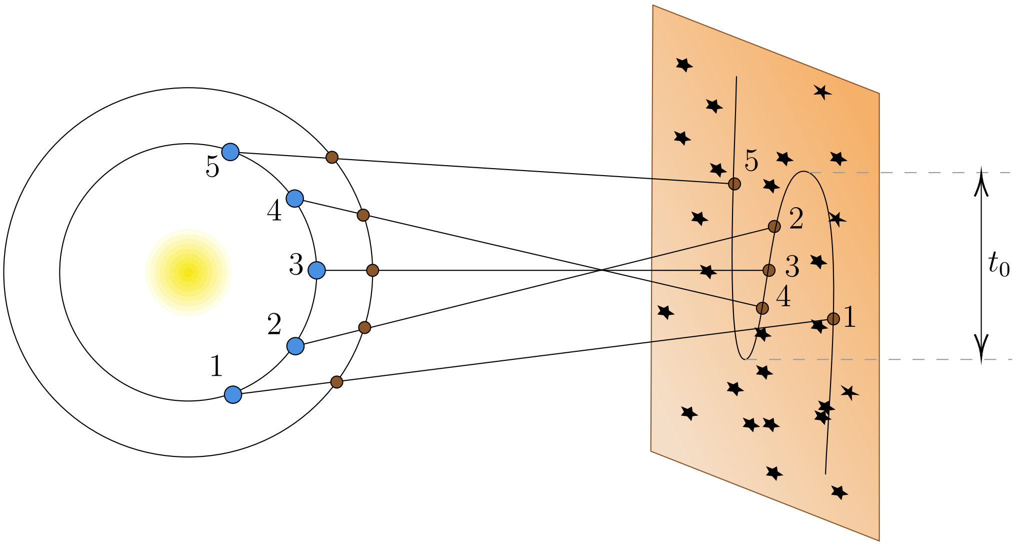
hence:

$$\boxed{t_0=\frac{T_2T_1}{2\pi(T_2-T_1)}\arccos\left(\frac{T_2^{4/3}T_1+T_1^{4/3}T_2}{T_1^{2/3}T_2^{2/3}(T_1+T_2)}\right)} \tag{12.1.557}$$

A numerical application with for Mercury $T_1\cong 87.95$ [d] and for Earth $T_2\cong 365.25$ [d] leads to the value:

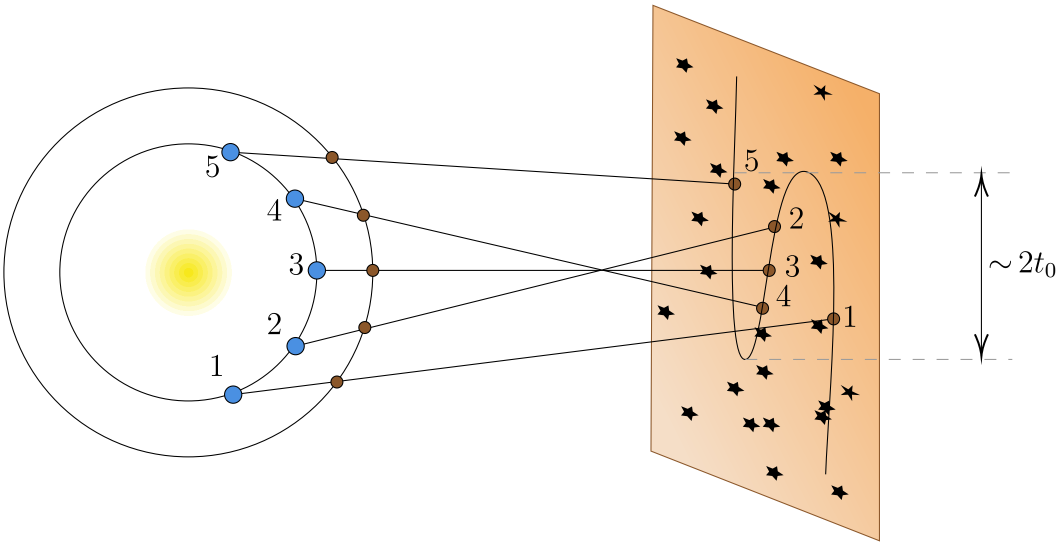
$$t_0\cong 11.44\,[\text{d}] \tag{12.1.558}$$

Value that we have represented in the diagram below:



5
4
3
2
1
5
2
3
4
1
t_0

and therefore:



5
4
3
2
1
5
2
3
4
1
$\sim 2t_0$

and therefore we have:

$$t_1 = \frac{T_1 T_2}{T_2 - T_1} \pm t_0 \cong 115.84 \pm 11.44 \tag{12.1.559}$$

then a new cycle:

$$t_2 = \frac{T_1 T_2}{T_2 - T_1} \pm t_1 \tag{12.1.560}$$

etc. What gives in schematic form:

Figure 12.76: Retrogradiation cycle diagram principle

Remark

At specific points on Mercury's surface, an observer would be able to see the Sun (actually a G2V-type star, aka yellow dwarf) rise part way, then reverse and set before rising again, all within the same Mercurian day. This apparent retrograde motion of the Sun occurs because, from approximately four Earth days before perihelion until approximately four Earth days after it, Mercury's angular orbital speed exceeds its angular rotational velocity. Mercury's elliptical orbit is farther from circular than that of any other planet in the Solar System, resulting in a substantially higher orbital speed near perihelion.

Figure 12.77: Real sequence of exposures showing Mars and Saturn retrograde motion (author: Tunç Tezel)

Let us see now how to simulate the retrograde motion on a computer of Mars relatively to Earth!

Since the eccentricities of the two planets are small (0.017 and 0.093), the two elliptical trajectories can be equated with circles (eccentricity equal to 0). Since Mars's inclination is small, the two trajectories can be equated, as a first approximation, with coplanar circles centered on the Sun.

To simplify matters further, we will use rounded data and study the following simplified model:

	Radius of the orbit (in half au)	**Revolution period** (in terrestrial year)
Earth	2	1
Mars	3.048	1.88

With this simplified model, the Sun, Earth, and Mars are aligned once a year. The respective positions of Earth and Mars (measured in half astronomical units) relative to the Sun can be written as a function of time t (measured in Earth years from the alignment) as complex numbers ($\mathrm{i}^2 = -1$):

$$\begin{cases} z_{E/S}(t) = 2e^{+2\pi\mathrm{i}t} \\ z_{M/S}(t) = 3.048e^{+\pi\mathrm{i}t} \end{cases} \tag{12.1.561}$$

We deduce that the relative position of Mars with respect to the Earth is given by:

$$z_{M/E}(t) = z_{M/S}(t) - z_{E/S}(t) = 3.048e^{+\pi\mathrm{i}t} - 2e^{+2\pi\mathrm{i}t} \tag{12.1.562}$$

Using Euler's property, $e^{\mathrm{i}x} = \cos(x) + \mathrm{i}\sin(x)$, and then separating the real part (abscissa) from the imaginary part (ordinate), we get the parametric equations of a "cardioid" (an irregular one because the real cardois hast the same coefficient in front of each trigonometric term):

$$\begin{cases} x = 3.048\cos(\pi t) - 2\cos(2\pi t) \\ y = 3.048\sin(\pi t) - 2\sin(2\pi t) \end{cases} \tag{12.1.563}$$

Notice that the choice that we did starts is such that at $t = 0$ we start with an opposition between Earth and Mars!

The representation of this relative position in the plane gives the following trajectory with Maple™ 4.00b (remember that the variable t is in unit of years, hence $t = 1$ is equivalent to one year):

```
>plot([3*cos(2/1.88*Pi*t) - 2*cos(2*Pi*t), 3*sin(2/1.88*Pi*t) -
2*sin(2*Pi*t) , t=0..2.5], scaling=constrained)
```

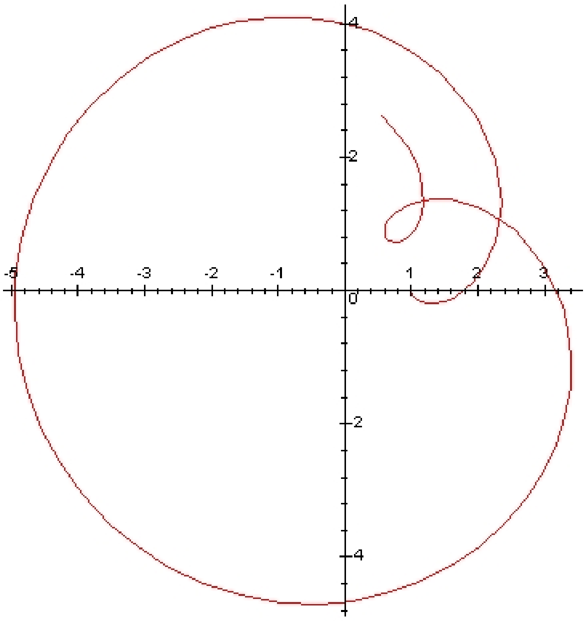

Figure 12.78: **Simulation of retrograde motion of Mars and Earth with Maple™ 4.00b**

Mars undergoes retrograde motion, which is an apparent back-and-forth movement in the sky, approximately every 26 months like visible in the plot above. This means that we can observe Mars retrograde roughly once every two years, or roughly 0.5 times per year. The retrograde period lasts about two and a half months.

Planetary retrogradation is a clear observational proof that we exist in a heliocentric system rather than a geocentric one. If the latter were true, planets would have to defy the principles of conservation of energy and angular momentum!

12.1.10 Equation of Time and Analemma

In astronomy, a "Sun analemma" is a diagram showing the position of the Sun (actually a G2V-type star, aka yellow dwarf) in the sky as seen from a fixed location on Earth at the same mean solar time, as that position varies over the course of a year. The diagram will resemble a figure eight seen from Earth nowadays (see further below for the detailed proof).

Figure 12.80: **Analemma as viewed from Antarctica**

More generaly an "analemma" is the closed, often figure-eight–shaped curve traced by the apparent position of a periodically observed object when it is recorded at the same clock time over many consecutive days.

Below we can see the Moon's analemma take by Wael Omar with its Canon 200 D, Canon 18-55 lens, Redcat 51 optics, GOTO mount (foreground image: ISO 100, 30 seconds, F 11):

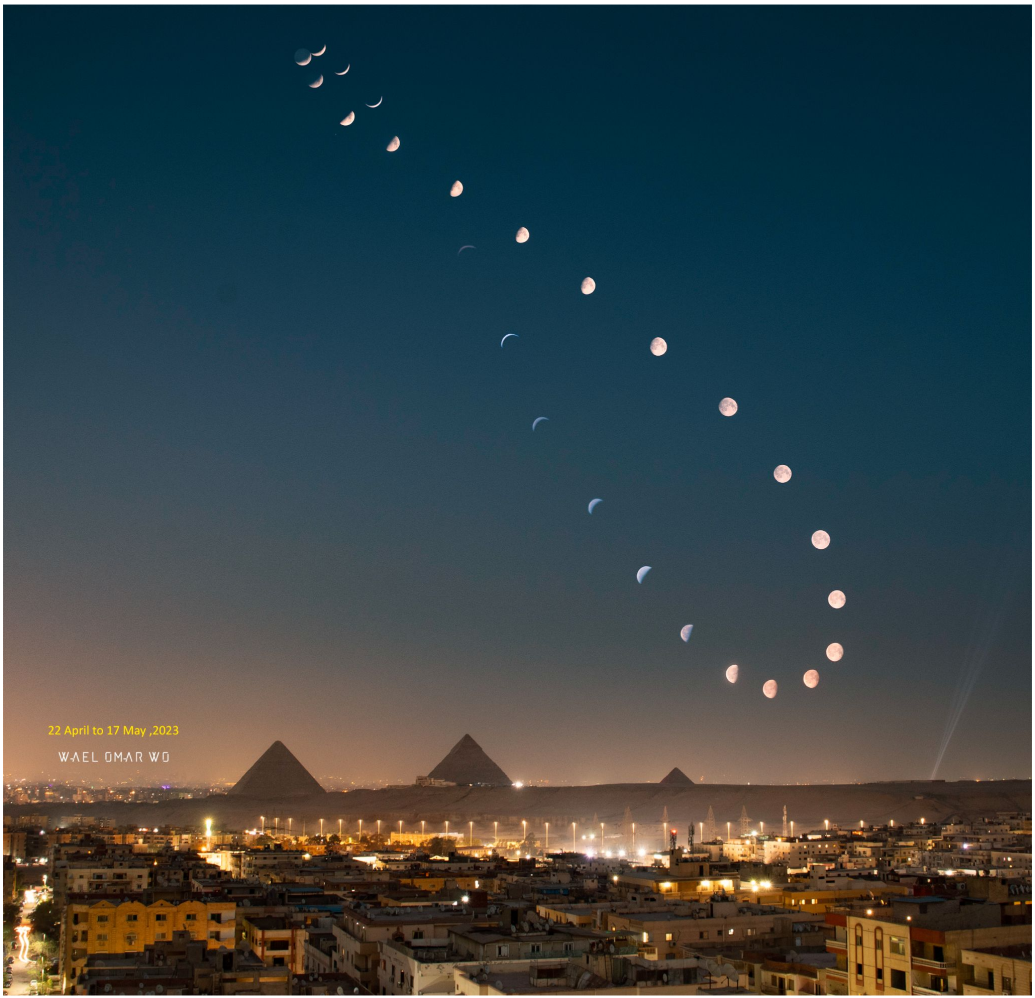

Figure 12.81: **Analemma viewed from Cairo/Egypt (author: Wael Omar)**

The North–South component of the analemma results from the change in the Sun's declination (angular distance of a celestial body North (+) or South (−) from the celestial equator) due to the tilt of Earth's axis of rotation as it orbits around the Sun. The east–west component results from the nonuniform rate of change of the Sun's right ascension (the celestial equivalent of longitude, measuring the East-West position of an astronomical object on the celestial sphere), governed by the combined effects of Earth's axial tilt and its orbital eccentricity[19].

One can photograph an analemma by keeping a camera at a fixed location and orientation and taking multiple exposures throughout the year, always at the same time of day (disregarding daylight saving time).

---

[19] The eccentricity of the Earth's orbit varies over time, due to gravitational interaction with other celestial bodies. The eccentricity value can get as low as 0.0034 and up to 0.058.

Although the term analemma usually refers to "Earth's solar analemma", it can be applied to other celestial bodies as well.

Remark

The text that follows is almost entirely inspired by the excellent paper *Equation of time - Problem in Astronomy* by Dr. Markus Müller (see [403]). His paper was awarded in the II International Competition (11993/94 according to holocene calendar). Notice that the first mathematical description of the analemma seems to have been made the French astronomer Grandjean de Fouchy in 11740 (holocene calendar).

We will deal here with a problem of the astronomical measurement of time. Let us first introduce some basic definitions!

Definitions (#12.1.528):

D1. The natural unit of time is the rotation of the Earth, that is the apparent daily course of the Sun. The length of time between two culminations of the Sun is named a "solar day". The time-system based on this unit is named "apparent solar time". By this system, localities on a given meridian always have the same time-readings.

D2. A comparison of a sundial with a mechanical clock shows that the solar day has a variable length. Therefore, so-named "mean solar time" is commonly used. This is based on a unit which is defined as the average of a solar day. The mean solar time has been fixed in such a way that it does not deviate too much from the apparent solar time. The deviations between apparent solar time and mean solar time are described by the equation of time:

$$\text{Equation of time} = (\text{Apparent solar time}) - (\text{Mean solar time}) \tag{12.1.564}$$

Suitable approximations and relevant aspects of the equation of time are discussed in what follows. The derivation does not account for minor effects due to the gravitational fields of the Moon and the planets. In principle, therefore, a comparison of the results of such an idealized equation of time with the actual observations can be used to estimate the magnitudes of these effects. Furthermore, parameters of the orbit of the Earth, such as its eccentricity, can be verified or calculated. It should be mentioned that the equation of time was very important for navigation in earlier times.

Two well-known features of our Solar System are at the basis of the variations in the apparent motion of the Sun:

1. According to Kepler's second law (see page 5234), the angular velocity of the Earth relative to the Sun varies throughout a year.
2. Equal angles which the Sun in its apparent movement goes through in the ecliptic do not correspond to equal angles we measure on the equatorial plane (see figure below). However, it is these latter angles which are relevant for the measurement of time, since the daily movement of the Sun is parallel to the equatorial plane.

So we will have to take into account these two factors: the eccentricity (variable angular velocity of the Earth) + the obliquity.

Let us start with the calculations of the first one!

12.1.10.1 Eccentricity component (variable angular velocity of Earth)

Definition (#12.1.529): The "celestial equator" is an extension of Earth's equator in space that bisects the sky into two hemisphere. The celestial equator is positioned at 0 degrees declination (angular distance of a celestial body North $(+)$ or South $(-)$ from the celestial equator), like Earth's equator is 0 degrees latitude. In other words the celestial equator is the great circle of the imaginary celestial sphere on the same plane as the equator of Earth. By extension, it is also a plane of reference in the equatorial coordinate system. Due to Earth's axial tilt, the celestial equator is currently inclined by about $23.44°$ with respect to the ecliptic (the plane of Earth's orbit).

Figure 12.82: **Apparent path of the Sun in a geocentric view. At the perihelion, the Sun runs faster than at the aphelion. Equal angles β on the plane of the ecliptic do not correspond to equal angles γ on the equatorial plane. In this figure there is $\beta_1 = \beta_2$ but $\gamma_1 < \gamma_2$.**

Kepler's first law tells us that all planets are moving in elliptical orbits around the sun, whereby the latter is positioned at one of the two focal points. Kepler's second law - the so-named "law of areas - describes the velocity of the planets (see page 5234). The area swept out per time interval is constant $(= \mathrm{d}S/\mathrm{d}t)$.

Hence, during the time period t the radius vector from the Sun to the Earth sweeps out an area of:

$$t\frac{\mathrm{d}S}{\mathrm{d}t} = t\frac{\pi ab}{T} = \frac{t}{T}\pi ab \qquad (12.1.565)$$

where a, b are the axes of the ellipse and T the duration of a revolution.

Let us now derive the angular velocity of the Earth as a function of time. The angle covered by the Earth after leaving the perihelion is named "true anomaly", denoted here with $\hat{R}$ as visible in the figure below:

Figure 12.83: **Angles $\hat{R}$, $\hat{M}$ and $\hat{E}$ at a specific time point. The affinity factor between the elliptical orbit and the circle going through the perihelion and the aphelion is given by b/a. As the angular velocity of the "real Earth" and the "mean Earth" are both constant, the ratio between the two hatched areas is the same as between the areas of the circle and the ellipse, viz., $1 : b/a$.**

Let us imagine a "mean Earth" which has also a revolution time T and is running at a constant speed on a circular orbit with the Sun at its centre. This "mean earth" would cover an angle, named "mean anomaly" $\hat{M}$, in the same period of time as the true Earth covers the angle R. In the figure above, M is drawn from the center of the ellipse. The orbit of the "mean Earth" is the circle through the perihelion and the aphelion. The "mean Earth" starts from the perihelion at the same time as the true earth. Since the angular velocity of the "mean Earth" is constant and its revolution lasts one year T, $\hat{M}$ satisfies the simple equation:

$$\hat{M} = 2\pi \frac{t}{T} \qquad (12.1.566)$$

where t is the time span after passage through the perihelion. It is very useful to define a third angle as a link between M and R (see figure above). The perpendicular drawn from the position of the true earth $\hat{E}$ onto the major axis intersects the circle, that is the orbit of the "mean Earth", at the point A. The angle $\widehat{PZA}$ is named "eccentric anomaly" denoted $\hat{E}$ and was introduced by Johannes Kepler. It can be used to calculate the area of elliptic sectors.

We get the following three relations from the figure above (we use also the relations see during our study of conics in the section of Analytical Geometry (page 2764):

$$\tan(\hat{R})=\frac{\overline{EB}}{\overline{SB}}=\frac{\frac{b}{a}\overline{AB}}{\overline{ZB}-\overline{ZS}}=\frac{\frac{b}{a}a\sin(\hat{E})}{a\cos(\hat{E})-ea}=\frac{b}{a}\frac{\sin(\hat{E})}{\cos(\hat{E})-e}=\frac{\sqrt{1-e^2}\sin(\hat{E})}{\cos(\hat{E})-e} \tag{12.1.567}$$

and (at the beginning we use a trigonometric identity - see page 2508 - to be able to use the result we got just before):

$$\begin{aligned}\cos(\hat{R})&=\sqrt{\frac{1}{1+\tan^2(\hat{R})}}=\sqrt{\frac{1}{1+\left(\frac{\sqrt{1-e^2}\sin(\hat{E})}{\cos(\hat{E})-e}\right)^2}}\\&=\sqrt{\frac{(\cos(\hat{E})-e)^2}{(\cos(\hat{E})-e)^2+(1-e^2)\sin^2(\hat{E})}}=\frac{\cos(\hat{E})-e}{1-e\cos(\hat{E})}\end{aligned} \tag{12.1.568}$$

and finally for the third and last one (at the beginning we use a remarkable trigonometric identity - see page 2519 - to be able to use the result we got just before):

$$\begin{aligned}\tan\left(\frac{\hat{R}}{2}\right)&=\sqrt{\frac{1-\cos(\hat{R})}{1+\cos(\hat{R})}}=\sqrt{\frac{1-\frac{\cos(\hat{E})-e}{1-e\cos(\hat{E})}}{1+\frac{\cos(\hat{E})-e}{1-e\cos(\hat{E})}}}=\sqrt{\frac{1-e\cos(\hat{E})-\cos(\hat{E})+e}{1-e\cos(\hat{E})+\cos(\hat{E})-e}}\\&=\sqrt{\frac{(1+e)(1-\cos(\hat{E}))}{(1-e)(1+\cos(\hat{E}))}}=\sqrt{\frac{1+e}{1-e}}\sqrt{\frac{1-\cos(\hat{E})}{1+\cos(\hat{E})}}=\sqrt{\frac{1+e}{1-e}}\tan\left(\frac{\hat{E}}{2}\right)\end{aligned} \tag{12.1.569}$$

To simplify the notations, let us now put:

$$\cos(\alpha):=\sqrt{\frac{1-e}{1+e}}\qquad y:=\frac{\hat{R}}{2}\qquad x:=\frac{\hat{E}}{2} \tag{12.1.570}$$

where as for reminder as $0<e<1$ we have therefore $0<\alpha<\pi/2$.

Therefore with this new notation, we have the relation:

$$\tan\left(\frac{\hat{R}}{2}\right)=\sqrt{\frac{(1+e)(1-\cos(\hat{E}))}{(1-e)(1+\cos(\hat{E}))}}=\sqrt{\frac{1+e}{1-e}}\sqrt{\frac{1-\cos(\hat{E})}{1+\cos(\hat{E})}}=\sqrt{\frac{1+e}{1-e}}\tan\left(\frac{\hat{E}}{2}\right) \tag{12.1.571}$$

that can be rewritten:

$$\tan(y)=\frac{\tan(x)}{\cos(\alpha)}\Leftrightarrow y=\arctan\left(\frac{\tan(x)}{\cos(\alpha)}\right) \tag{12.1.572}$$

The differentiation of this last equality gives us (see section Differential and Integral Calculus page 1475):

$$\begin{aligned}\frac{\mathrm{d}y}{\mathrm{d}x}&=\frac{1}{\left(\frac{\tan(x)}{\cos(\alpha)}\right)^2+1}\cdot\frac{\mathrm{d}}{\mathrm{d}x}\left[\frac{\tan(x)}{\cos(\alpha)}\right]=\frac{\frac{1}{\cos(\alpha)}\cdot\frac{\mathrm{d}}{\mathrm{d}x}[\tan(x)]}{\frac{\tan^2(x)}{\cos^2(\alpha)}+1}\\&=\frac{\frac{1}{\cos(\alpha)}\cdot\frac{1}{\cos^2(x)}}{\frac{(\sin(x)/\cos(x))^2}{\cos^2(\alpha)}+\cos^2(x)}=\frac{\frac{1}{\cos(\alpha)}}{\frac{\sin^2(x)}{\cos^2(\alpha)}+\cos^2(x)}=\frac{\cos(\alpha)}{\sin^2(x)+\cos^2(\alpha)\cos^2(x)}\\&=\frac{\cos(\alpha)}{\sin^2(x)+(1-\sin^2(\alpha))\cos^2(x)}\\&=\frac{\cos(\alpha)}{1-\sin^2(\alpha)\cos^2(x)}=\frac{\cos(\alpha)}{1-\sin^2(\alpha)\frac{(1+\cos(2x))}{2}}\\&=\frac{2\cos(\alpha)}{1+\cos^2(\alpha)-\sin^2(\alpha)\cos(2x)}\end{aligned}\tag{12.1.573}$$

Since:

$$f(x):=\frac{\mathrm{d}y}{\mathrm{d}x}=\frac{\cos(\alpha)}{1-\sin^2(\alpha)\cos^2(x)}\tag{12.1.574}$$

it can be expanded into a Fourier series (see section Sequences and Series page 1727):

$$\begin{aligned}f(x)&=\sum_{n=0}^{+\infty}(a_n\cos(nx)+b_n\sin(nx))\\&=a_0+a_1\cos(x)+b_1\sin(x)+\ldots+a_n\cos(nx)+b_n\sin(nx)+\ldots\end{aligned}\tag{12.1.575}$$

with typically in our special case here:

$$a_0=\frac{1}{2\pi}\int\limits_0^{2\pi}f(x)\mathrm{d}x=\frac{1}{2\pi}\int\limits_0^{2\pi}\frac{\mathrm{d}y}{\mathrm{d}x}\mathrm{d}x=\frac{1}{2\pi}\int\limits_0^{2\pi}\mathrm{d}y=1\tag{12.1.576}$$

and:

$$a_n=\frac{1}{\pi}\int\limits_0^{2\pi}f(x)\cos(nx)\mathrm{d}x\qquad b_n=\frac{1}{\pi}\int\limits_0^{2\pi}f(x)\sin(nx)\mathrm{d}x\text{ for }n>0\tag{12.1.577}$$

Hence:

$$a_n=\frac{1}{\pi}\int\limits_0^{2\pi}f(x)\cos(nx)\mathrm{d}x=\frac{1}{\pi}\int\limits_0^{2\pi}\left(\frac{2\cos(\alpha)}{1+\cos^2(\alpha)-\sin^2(\alpha)\cos(2x)}\right)\cos(nx)\mathrm{d}x\tag{12.1.578}$$

Replacing $\cos(x)$ and $\cos(2x)$ by the complex exponential function - i.e. the Euler formulas - yields ((see section Numbers page 251)):

$$\cos(\varphi)=\frac{e^{\mathrm{i}\varphi}+e^{-\mathrm{i}\varphi}}{2}\tag{12.1.579}$$

Hence:

$$a_n=\frac{1}{\pi}\int\limits_0^{2\pi}\frac{\cos(\alpha)\left(e^{\mathrm{i}nx}+e^{-\mathrm{i}nx}\right)}{1+\cos^2(\alpha)-\sin^2(\alpha)\left(\frac{e^{2\mathrm{i}x}+e^{-2\mathrm{i}x}}{2}\right)}\mathrm{d}x\tag{12.1.580}$$

Let us put:

$$z = e^{2\mathrm{i}x} \Rightarrow \frac{\mathrm{d}z}{\mathrm{d}x} = 2\mathrm{i}e^{2\mathrm{i}x} = 2\mathrm{i}z \Rightarrow \mathrm{d}x = -\frac{\mathrm{i}}{2z}\mathrm{d}z \tag{12.1.581}$$

Therefore:

$$\begin{aligned} a_n &= \frac{\mathrm{i}}{\pi}\int_0^{2\pi} \frac{\cos(\alpha)\left(z^{n/2}+z^{-n/2}\right)}{-2z\left[1+\cos^2(\alpha)-\sin^2(\alpha)\left(\frac{z+z^{-1}}{2}\right)\right]}\mathrm{d}z \\ &= \frac{\mathrm{i}}{\pi}\int_0^{2\pi} \frac{\cos(\alpha)\left(z^{n/2}+z^{-n/2}\right)}{-2z\left[1+\cos^2(\alpha)-\sin^2(\alpha)\left(\frac{z^2+1}{2z}\right)\right]}\mathrm{d}z \\ &= \frac{\mathrm{i}}{\pi}\int_0^{2\pi} \frac{\cos(\alpha)\left(z^{n/2}+z^{-n/2}\right)}{-2z(1+\cos^2(\alpha))+\sin^2(\alpha)(z^2+1)}\mathrm{d}z \\ &= \frac{\mathrm{i}}{\pi}\oint \frac{\cos(\alpha)\left(z^{n/2}+z^{-n/2}\right)}{\sin^2(\alpha)\left(z^2-2\frac{(1+\cos^2\alpha)}{\sin^2\alpha}z+1\right)}\mathrm{d}z \end{aligned} \tag{12.1.582}$$

Because of the change of variable and the exponent of the exponential having a factor 2, the contour of integration is twice the unit circle!

Now we use complex analysis. The denominator has the roots:

$$r_1 = \frac{2-\sin(\alpha)^2+2\sqrt{1-\sin(\alpha)^2}}{\sin(\alpha)^2}, r_2 = \frac{2-\sin(\alpha)^2-2\sqrt{1-\sin(\alpha)^2}}{\sin(\alpha)^2} \tag{12.1.583}$$

That can be simplified:

$$r_1 = \frac{2-\sin(\alpha)^2+2|\cos(\alpha)|}{\sin(\alpha)^2}, r_2 = \frac{2-\sin(\alpha)^2-2|\cos(\alpha)|}{\sin(\alpha)^2} \tag{12.1.584}$$

And as we have $2-\sin^2(\alpha) = 1+1-\sin^2(\alpha) = 1+\cos^2(\alpha)$, we get:

$$r_1 = \frac{1+\cos^2(\alpha)+2|\cos(\alpha)|}{\sin(\alpha)^2}, r_2 = \frac{2-\sin(\alpha)^2-2|\cos(\alpha)|}{\sin(\alpha)^2} \tag{12.1.585}$$

For all $\alpha \in \mathbb{R}$, $\cos(\alpha)$ is either negative or non-negative. If it is negative, $|\cos(\alpha)| = -\cos(\alpha)$ and so:

$$\frac{1+\cos^2(\alpha)+2|\cos(\alpha)|}{\sin^2(\alpha)} = \frac{1+\cos^2(\alpha)-2\cos(\alpha)}{\sin^2(\alpha)} = \left(\frac{1-\cos(\alpha)}{\sin(\alpha)}\right)^2 = \tan^2\left(\frac{\alpha}{2}\right) \tag{12.1.586}$$

If, instead, it is non-negative, then $|\cos(\alpha)| = \cos(\alpha)$ and so:

$$\frac{1+\cos^2(\alpha)+2|\cos(\alpha)|}{\sin^2(\alpha)} = \frac{1+\cos^2(\alpha)+2\cos(\alpha)}{\sin^2(\alpha)} = \left(\frac{1+\cos(\alpha)}{\sin(\alpha)}\right)^2 = \cot^2\left(\frac{\alpha}{2}\right) \tag{12.1.587}$$

This is one of the two roots. The other root is going to just be the other case. There is thus never a difference; you will always get both $\tan^2(\alpha/2)$ and $\cot^2(\alpha/2)$ as the two roots, for all possible $\alpha \in \mathbb{R}$. It is just a matter of which one we pick first.

Therefore the previous curvilinear integral can be rewritten as:

$$\begin{aligned}a_n&=\frac{\mathrm{i}}{\pi}\oint\frac{\cos(\alpha)}{\sin^2(\alpha)}\frac{\left(z^{n/2}+z^{-n/2}\right)}{\left(z-\tan^2\left(\frac{\alpha}{2}\right)\right)\left(z-\cot^2\left(\frac{\alpha}{2}\right)\right)}\mathrm{d}z\\&=\frac{\mathrm{i}}{\pi}\oint\frac{\cos(\alpha)}{\sin^2(\alpha)}\frac{\left(z^{n/2}+z^{-n/2}\right)}{\tan^2\left(\frac{\alpha}{2}\right)-\cot^2\left(\frac{\alpha}{2}\right)}\left[\frac{1}{z-\tan^2\left(\frac{\alpha}{2}\right)}-\frac{1}{z-\cot^2\left(\frac{\alpha}{2}\right)}\right]\mathrm{d}z\end{aligned} \tag{12.1.588}$$

Now remember that we have proven in the section of Sequences and Series (see page 1679) that:

$$\frac{1}{1-x}=\sum_{n=0}^{+\infty}x^n \text{ for } |x|<1 \tag{12.1.589}$$

So now let us rewrite:

$$\frac{1}{z-\tan^2\left(\frac{\alpha}{2}\right)}=\frac{1}{z}\frac{1}{1-\dfrac{\tan^2\left(\frac{\alpha}{2}\right)}{z}} \tag{12.1.590}$$

Now remember that we have defined earlier above:

$$\cos(\alpha):=\sqrt{\frac{1-e}{1+e}} \tag{12.1.591}$$

and as the modulus of z is always equal to 1 we satisfy the criteria of convergent series and we are authorized therefore to write:

$$\frac{1}{z-\tan^2\left(\frac{\alpha}{2}\right)}=\frac{1}{z}\sum_{k=0}^{+\infty}\left(\frac{\tan^2\left(\frac{\alpha}{2}\right)}{z}\right)^k \tag{12.1.592}$$

As $\cot(\alpha/2)=1/\tan(\alpha/2)$, we have:

$$\begin{aligned}-\frac{1}{z-\cot^2\left(\frac{\alpha}{2}\right)}&=-\frac{1}{z-\frac{1}{\tan^2\left(\frac{\alpha}{2}\right)}}=-\tan^2\left(\frac{\alpha}{2}\right)\frac{1}{z\tan^2\left(\frac{\alpha}{2}\right)-1}=\tan^2\left(\frac{\alpha}{2}\right)\frac{1}{1-z\tan^2\left(\frac{\alpha}{2}\right)}\\&=\tan^2\left(\frac{\alpha}{2}\right)\sum_{k=0}^{+\infty}\left(z\tan^2\left(\frac{\alpha}{2}\right)\right)^k\end{aligned} \tag{12.1.593}$$

The integrand:

$$a_n=\frac{\mathrm{i}}{\pi}\oint\frac{\cos(\alpha)}{\sin^2(\alpha)}\frac{\left(z^{n/2}+z^{-n/2}\right)}{\tan^2\left(\frac{\alpha}{2}\right)-\cot^2\left(\frac{\alpha}{2}\right)}\left[\frac{1}{z-\tan^2\left(\frac{\alpha}{2}\right)}-\frac{1}{z-\cot^2\left(\frac{\alpha}{2}\right)}\right]\mathrm{d}z \tag{12.1.594}$$

Then becomes (we also used a trigonometric identity proven at page 2519):

$$a_n=-\frac{\mathrm{i}}{4\pi}\oint\left(z^{n/2}+z^{-n/2}\right)\left\{\frac{1}{z}\sum_{k=0}^{+\infty}\left[\frac{\tan^2\left(\frac{\alpha}{2}\right)}{z}\right]^k+\tan^2\left(\frac{\alpha}{2}\right)\sum_{k=0}^{+\infty}\left[z\tan^2\left(\frac{\alpha}{2}\right)\right]^k\right\} \tag{12.1.595}$$

Now, let us notice that:

$$\oint z^p \mathrm{d}z = \int\limits_{e^0}^{e^{4\mathrm{i}\pi}} z^p \mathrm{d}z = \left.\frac{z^{(p+1)}}{p+1}\right|_{e^0}^{e^{4\mathrm{i}\pi}} = \frac{1}{p+1} - \frac{1}{p+1} \tag{12.1.596}$$

However we have to consider the singularity (division by zero) for the case $p = -1$. In that case:

$$\oint z^p \mathrm{d}z = \int\limits_{e^0}^{e^{4\mathrm{i}\pi}} z^{-1} \mathrm{d}z = \ln(z)|_{e^0}^{e^{4\mathrm{i}\pi}} = 4\pi\mathrm{i} \tag{12.1.597}$$

So finally:

$$\oint z^p \mathrm{d}z = \int\limits_{e^0}^{e^{4\mathrm{i}\pi}} z^p \mathrm{d}z = \left.\frac{z^{(p+1)}}{p+1}\right|_{e^0}^{e^{4\mathrm{i}\pi}} = \begin{cases} 0 & \text{for} \quad p \neq -1 \\ 4\mathrm{i}\pi & \text{for} \quad p = -1 \end{cases} \tag{12.1.598}$$

So that means for the integral that gives a_n we only have to consider the terms where $z^{n/2} = z^{-1}$ as all other will vanished! For that a first minimal condition are the powers in the parenthesis:

$$\left(z^{n/2} + z^{-n/2}\right) \tag{12.1.599}$$

to be integers obviously! Consequently the integral is zero if n is odd, that is, a_n vanishes if n is odd.

How can this be useful to us ? Consequently, the integral is zero if n is odd, that is, a_n vanishes if n is odd. $a_n = 0$ for odd n. If n is even we can only keep the terms with a $1/z$ (all others like $z, z^2, z^3, \ldots$ and $z^{-2}, z^{-3}, z^{-4} \ldots$ will be zero so we don't keep them!), then if we develop by some n we notice quite quickly that it remains the following pattern of even $n > 0$:

$$\begin{aligned} a_n &= -\frac{\mathrm{i}}{4\pi} \oint \frac{1}{z} \left[\tan^n\left(\frac{\alpha}{2}\right) + \tan^2\left(\frac{\alpha}{2}\right)\tan^{-2+n}\left(\frac{\alpha}{2}\right)\right] \\ &= -\frac{\mathrm{i}}{4\pi} \oint \frac{1}{z} \left[\tan^n\left(\frac{\alpha}{2}\right) + \tan^n\left(\frac{\alpha}{2}\right)\right] \\ &= -\frac{\mathrm{i}}{2\pi}\frac{1}{z}\tan^n\left(\frac{\alpha}{2}\right) \end{aligned} \tag{12.1.600}$$

The integration of this term yields:

$$a_n = -\frac{\mathrm{i}}{2\pi}\tan^n\left(\frac{\alpha}{2}\right) \int_{\mathrm{e}^0}^{\mathrm{e}^{4\mathrm{i}\pi}} \frac{1}{z}\mathrm{d}z = -\frac{\mathrm{i}}{2\pi}\tan^n\left(\frac{\alpha}{2}\right) 4\mathrm{i}\pi = 2\tan^n\left(\frac{\alpha}{2}\right) \tag{12.1.601}$$

The coefficients b_n can be obtained similarly. If n is odd, b_n disappears. If n is even, one has to write instead of:

$$a_n = -\frac{\mathrm{i}}{4\pi} \oint \frac{1}{z} \left[\tan^n\left(\frac{\alpha}{2}\right) + \tan^2\left(\frac{\alpha}{2}\right)\tan^{-2+n}\left(\frac{\alpha}{2}\right)\right] = 2\tan^n\left(\frac{\alpha}{2}\right) \tag{12.1.602}$$

the following:

$$b_n = -\frac{1}{4\pi} \oint \frac{1}{z} \left[\tan^n\left(\frac{\alpha}{2}\right) - \tan^n\left(\frac{\alpha}{2}\right)\right] = 0 \tag{12.1.603}$$

Therefore:

$$\begin{aligned}f(x)=\frac{\mathrm{d}y}{\mathrm{d}x}&=\frac{\cos(\alpha)}{1-\sin^2(\alpha)\cos^2(x)}\\&=\sum_{n=0}^{+\infty}(a_n\cos(nx)+b_n\sin(nx))\\&=a_0+a_1\cos(x)+b_1\sin(x)+\ldots+a_n\cos(nx)+b_n\sin(nx)+\ldots\\&=1+2\sum_{k=1}^{+\infty}\tan^{2k}\left(\frac{\alpha}{2}\right)\cos(2kx)\end{aligned} \tag{12.1.604}$$

Hence:

$$y=x+\sum_{k=1}^{+\infty}\tan^{2k}\left(\frac{\alpha}{2}\right)\frac{\sin(2kx)}{k}+c^{te} \tag{12.1.605}$$

Now remember that at the beginning we have constructed the following relation:

$$\tan\left(\frac{\hat{R}}{2}\right)=\sqrt{\frac{1+e}{1-e}}\tan\left(\frac{\hat{E}}{2}\right) \tag{12.1.606}$$

and that we had defined:

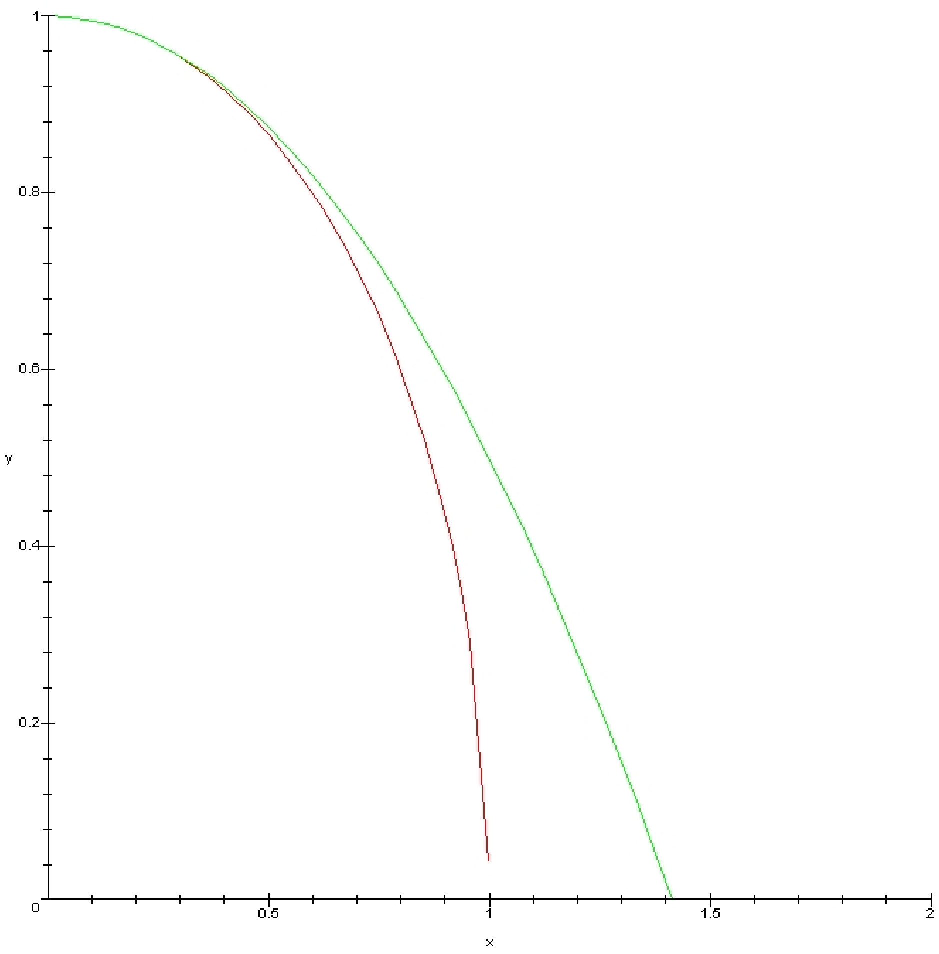
$$\cos(\alpha):=\sqrt{\frac{1-e}{1+e}} \tag{12.1.607}$$

We can rewrite it using trigonometric identities (see page 2519) as:

$$\begin{aligned}\tan^2\left(\frac{\alpha}{2}\right)&=\frac{1-\cos(\alpha)}{1+\cos(\alpha)}=\frac{1-\sqrt{\frac{1-e}{1+e}}}{1+\sqrt{\frac{1-e}{1+e}}}=\frac{1-\sqrt{\frac{1-e}{1+e}}}{1+\sqrt{\frac{1-e}{1+e}}}\frac{1-\sqrt{\frac{1-e}{1+e}}}{1-\sqrt{\frac{1-e}{1+e}}}\\&=\frac{1-2\sqrt{\frac{1-e}{1+e}}+\frac{1-e}{1+e}}{1-\frac{1-e}{1+e}}=\frac{1+e+1-e-2\sqrt{1-e^2}}{1+e-1+e}=\frac{1-\sqrt{1-e^2}}{e}\end{aligned} \tag{12.1.608}$$

If we do a Maclaurin development to the fourth term of the square root (see section Sequences and Series page 1696), even if that's not so good as we can check it with Maple™ 4.00b (the red is the exact value, the green the approximation!):

```
>plot(sqrt(1-x2̂),convert(taylor(sqrt(1-x2̂),x=0,4),polynom),x=0...2,y=0..1);
```



We can write:

$$\tan^2\left(\frac{\alpha}{2}\right)=\frac{1-\sqrt{1-e^2}}{e}\cong\frac{1-\left(1-\frac{e^2}{2}-\frac{e^4}{8}\right)}{e}=\frac{e}{2}+\frac{e^3}{8}\qquad(12.1.609)$$

Now putting all together, we have that:

$$y=x+\sum_{k=1}^{+\infty}\tan^{2k}\left(\frac{\alpha}{2}\right)\frac{\sin(2kx)}{k}+c^{te}\qquad(12.1.610)$$

with as initial condition that $R(E=0)=0$ (the constant is therefore equal to zero), and remembering all change of variables done at the beginning, that:

$$\hat{R}\cong\hat{E}+2\sum_{k=1}^{+\infty}\left(\frac{e}{2}+\frac{e^3}{8}\right)^k\frac{\sin(k\hat{E})}{k}\cong\hat{E}+\left(e+\frac{e^3}{4}\right)\sin(E)+\frac{e^2}{4}\sin(2\hat{E})+\frac{e^3}{12}\sin(3\hat{E})\qquad(12.1.611)$$

So we have here an approximation of already something that is a quite significant approximation (that makes a lot of approximations...).

The angle $\hat{E}$ is so useful because the area swept out by the radius vector from the Sun to the Earth in the time span t can be calculated easily by using the affinity between the circle and the ellipse (see the first figure above):

$$\begin{aligned} F &= \text{elliptic sector } SEP = \frac{b}{a}(\text{sector } ZAP - \text{triangle } ZAS) \\ &= \frac{b}{a}\left(\frac{\hat{E}}{2\pi}\text{area}_{\text{ circle}} - \frac{\overline{ZS}\cdot\overline{AB}}{2}\right) = \frac{b}{a}\left(\frac{\hat{E}}{2}a^2 - \frac{aea\sin(\hat{E})}{2}\right) \\ &= \frac{b}{a}\left(\frac{\hat{E}}{2}a^2 - a^2\frac{e\sin(\hat{E})}{2}\right) = \frac{ab}{2}(\hat{E} - e\sin(\hat{E})) \end{aligned} \tag{12.1.612}$$

On the other hand, the law of areas implies (see page 5234):

$$F = \frac{t}{T}\pi ab \tag{12.1.613}$$

or with:

$$\hat{M} = \frac{t}{T}2\pi \tag{12.1.614}$$

on gets:

$$F = \frac{Mab}{2} \tag{12.1.615}$$

The comparison with:

$$F = \frac{ab}{2}(\hat{E} - e\sin(\hat{E})) \tag{12.1.616}$$

yields:

$$\hat{E} = \hat{M} + e\sin(\hat{E}) \tag{12.1.617}$$

The relation above is named the "Kepler's equation". It is not possible to solve this equation for $\hat{E}$ in closed form. Therefore, the position of the earth - given by $\hat{E}$ - can only be approximated as a function of time. The Lagrange inversion theorem (see section Sequences and Series page page 1725) allows us to expand any function in $\hat{E}$ into a series in e and $\hat{E}$. Its basis is an equation in the form:

$$z = y + xf(z) \tag{12.1.618}$$

can be expanded for small α as a series expressed by:

$$z = y + \sum_{k=1}^{+\infty}\frac{x^k}{k!}\frac{\partial^{k-1}}{\partial y^{k-1}}f^k(y) \tag{12.1.619}$$

In the case of Kepler's equation, we set:

$$z = \hat{E}, \quad y = \hat{M}, \quad x = e, \quad f(\cdot) = \sin(\cdot), \quad f(z) = \sin(\hat{E}), \quad f(y) = \sin(\hat{M}) \tag{12.1.620}$$

Therefore we see that as in our case $x = e \cong 1$ this approximation by the Lagrange inversion theorem is another brutal approximation. $\hat{E}$ turns out therefore to be (using some trigonometric identities at the end as proven in the section of Trigonometry at page 2519):

$$\begin{aligned}\hat{E}&=\hat{M}+e\sin(\hat{M})+\frac{e^2}{2}\frac{\partial}{\partial\hat{M}}\sin^2(\hat{M})+\frac{e^3}{6}\frac{\partial^2}{\partial\hat{M}^2}\sin^3(\hat{M})+\ldots\\&=\hat{M}+e\sin(\hat{M})+\frac{e^2}{2}2\sin(\hat{M})\cos(\hat{M})+\frac{e^3}{6}\left[6\sin(\hat{M})\cos^2(\hat{M})-3\sin^3(\hat{M})\right]+\ldots\\&=\hat{M}+e\sin(\hat{M})+\frac{e^2}{2}2\sin(\hat{M})\cos(\hat{M})+\frac{e^3}{6}\left[\frac{6}{4}\sin(x)+\frac{6}{4}\sin(3x)-\frac{9}{4}\sin(x)-\frac{3}{4}\sin(3x)\right]+\ldots\\&=\hat{M}+e\sin(\hat{M})+\frac{e^2}{2}2\sin(\hat{M})\cos(\hat{M})+\frac{e^3}{6}\left[-\frac{3}{4}\sin(x)+\frac{3}{4}\sin(3x)\right]+\ldots\\&=\hat{M}+e\sin(\hat{M})+\frac{e^2}{2}2\sin(\hat{M})\cos(\hat{M})+e^3\left[-\frac{1}{8}\sin(x)+\frac{1}{8}\sin(3x)\right]+\ldots\\&=\hat{M}+e\sin(\hat{M})+\frac{e^2}{2}\sin(2\hat{M})+\frac{e^3}{8}\left(\sin(3\hat{M})-\sin(\hat{M})\right)+\ldots\end{aligned} \tag{12.1.621}$$

where we used the following trigonometric identities (we repeat them here as request by a reader):

$$\sin(x)\cos(y)=\frac{1}{2}(\sin(x-y)+\sin(x+y))$$

$$\begin{aligned}\sin(x)\cos^2(x)&=\sin(x)\left[\frac{1}{2}(1+\cos(2x))\right]=\frac{1}{2}\sin(x)+\frac{1}{2}\sin(x)\cos(2x)\\&=\frac{1}{2}\sin(x)+\frac{1}{2}\left[\frac{1}{2}(\sin(x-2x)+\sin(x+2x))\right]\\&=\frac{1}{2}\sin(x)+\frac{1}{2}\left[\frac{1}{2}(\sin(-x)+\sin(3x))\right]\\&=\frac{1}{2}\sin(x)+\frac{1}{4}\left[-\sin(x)+\sin(3x)\right]\\&=\frac{1}{4}\sin(x)+\frac{1}{4}\sin(3x)\end{aligned} \tag{12.1.622}$$

$$\begin{aligned}\sin^3(x)&=\sin(x)\cdot\sin^2(x)=\sin(x)\left(\frac{1}{2}-\frac{1}{2}\cos(2x)\right)\\&=\frac{1}{2}\sin(x)-\frac{1}{2}\sin(x)\cos(2x)\\&=\frac{1}{2}\sin(x)-\frac{1}{2}\left[\frac{1}{2}\sin(3x)+\frac{1}{2}\sin(-x)\right]\\&=\frac{1}{2}\sin(x)-\frac{1}{4}\sin(3x)-\frac{1}{4}\sin(-x)\\&=\frac{1}{2}\sin(x)-\frac{1}{4}\sin(3x)+\frac{1}{4}\sin(x)\\&=\frac{3}{4}\sin(x)-\frac{1}{4}\sin(3x)\end{aligned}$$

To be able to express $\hat{R}$ as a function of $\hat{M}$ in the relation we got earlier above:

$$\hat{R}\cong\hat{E}+\left(e+\frac{e^3}{4}\right)\sin(\hat{E})+\frac{e^2}{4}\sin(2\hat{E})+\frac{e^3}{12}\sin(3\hat{E}) \tag{12.1.623}$$

we also have to expand the sine functions of $E, 2E$ and $3E$ as far as needed:

$$\sin(\hat{E})=\frac{\hat{E}-\hat{M}}{e}=\sin(\hat{M})+\frac{e}{2}\sin(2\hat{M})+\frac{e^2}{8}(3\sin(3\hat{M})-\sin(\hat{M}))+\ldots \tag{12.1.624}$$

As:

$$\hat{E}=\hat{M}+e\sin(\hat{E}) \tag{12.1.625}$$

Thus:

$$\sin(2\hat{E})=\sin\left(2\hat{M}+2e\sin(\hat{E})\right) \tag{12.1.626}$$

Now we Taylor expand the sine according to (see section Sequences and Series page 1703):

$$\begin{aligned}
f_3(x)&\cong\sin(x)\\
&\cong\sum_{k=0}^{3}\frac{1}{k!}\frac{\mathrm{d}^kP(x)}{\mathrm{d}x^k}x^k=\frac{1}{0!}\frac{\mathrm{d}^0P(x)}{\mathrm{d}x^0}x^0+\frac{1}{1!}\frac{\mathrm{d}^1P(x)}{\mathrm{d}x^1}x^1+\frac{1}{2!}\frac{\mathrm{d}^2P(x)}{\mathrm{d}x^2}x^2+\frac{1}{3!}\frac{\mathrm{d}^3P(x)}{\mathrm{d}x^3}x^3\\
&=\frac{1}{0!}\sin(x)+\frac{1}{1!}\frac{\mathrm{d}\sin(x)}{\mathrm{d}x}x^1+\frac{1}{2!}\frac{\mathrm{d}^2\sin(x)}{\mathrm{d}x^2}x^2+\frac{1}{3!}\frac{\mathrm{d}^3\sin(x)}{\mathrm{d}x^3}x^3\\
&=\frac{1}{0!}\sin(x)+\frac{1}{1!}\cos(x)x-\frac{1}{2!}\sin(x)x^2-\frac{1}{3!}\cos(x)x^3\\
&=\sin(x)+\cos(x)x-\frac{1}{2}\sin(x)x^2-\frac{1}{6}\cos(x)x^3
\end{aligned} \tag{12.1.627}$$

but in e around 0. Therefore at the second order:

$$f_2(x)\cong\sin(x)=\sin(x)+\cos(x)x=\sin(2\hat{M})+\cos(2\hat{M})2\sin(\hat{E})\cdot e\cong sin(2\hat{E}) \tag{12.1.628}$$

So to summarize:

$$\begin{aligned}
\sin(\hat{E})&=\frac{\hat{E}-\hat{M}}{e}=\sin(\hat{M})+\frac{e}{2}\sin(2\hat{M})+\frac{e^2}{8}(3\sin(3\hat{M})-\sin(\hat{M}))+\ldots\\
\sin(2\hat{E})&=\sin(2\hat{M})+e\sin(\hat{M})2\cos(2\hat{M})+\ldots\\
&=\sin(2\hat{M})+e(\sin(3\hat{M})-\sin(\hat{M}))+\ldots\\
\sin(3\hat{E})&=\sin(3\hat{M})+\ldots
\end{aligned} \tag{12.1.629}$$

Replacing the functions in $\hat{E}$ of:

$$\hat{R}\cong\hat{E}+\left(e+\frac{e^3}{4}\right)\sin(\hat{E})+\frac{e^2}{4}\sin(2\hat{E})+\frac{e^3}{12}\sin(3\hat{E}) \tag{12.1.630}$$

with these formulas in $\hat{M}$, we get:

$$\begin{aligned}
\hat{R}&\cong\hat{E}+\left(e+\frac{e^3}{4}\right)\sin(\hat{E})+\frac{e^2}{4}\sin(2\hat{E})+\frac{e^3}{12}\sin(3\hat{E})\\
&\cong\hat{M}+\left(2e+\frac{e^3}{4}\right)\sin(\hat{E})+\frac{e^2}{4}\sin(2\hat{E})+\frac{e^3}{12}\sin(3\hat{E})\\
&\cong\hat{M}+2e\sin(\hat{M})+\frac{5}{4}e^2\sin(2\hat{M})+e^3\left(-\frac{1}{4}\sin(\hat{M})+\frac{13}{12}\sin(3\hat{M})\right)+e^4\ldots
\end{aligned} \tag{12.1.631}$$

In this series, we have only taken into account terms up to third power of e (this approximation is already very accurate, for e is about 0.0167). The angular velocity of the Earth can now be obtained as the first derivative of $\hat{R}$ with respect to time:

$$\begin{aligned}\omega(t) &= \frac{\mathrm{d}\hat{R}}{\mathrm{d}t} = \frac{\mathrm{d}\hat{R}}{\mathrm{d}\hat{M}}\frac{\mathrm{d}\hat{M}}{\mathrm{d}t} = \frac{2\pi}{T}\frac{\mathrm{d}\hat{R}}{\mathrm{d}\hat{M}} \\ &\cong \frac{2\pi}{T}\left[1+2e\cos(\hat{M})+\frac{5}{2}e^2\cos(2\hat{M})+e^3\left(-\frac{1}{4}\cos(\hat{M})+\frac{13}{4}\cos(3\hat{M})\right)\right]\end{aligned} \tag{12.1.632}$$

This function of the angular velocity of the Earth as function of the angle $\hat{M}$ is plotted in the figure below (with for the Earth actually $e=0.0167$, $T=365.25$) with Maple™ 4.00b (on average it is about $2\pi/365.25$ per day or $360/365.25°/\text{day}=0.986°/\text{day}$ or $0.0172\,[\text{rad}]/\text{day}$). It is mainly determined by the first variable term of the series $2e\cos(\hat{M})$. The factor $2\pi/T$ is the mean angular velocity. The deviations amount to about $\pm 3.5\%(\approx 2e)$:

```
>e:=0.0167;
>T:=365.25;
>plot(2*Pi/T*(1+2*e*cos(M)+5/2*e^2*cos(2*M)
+e^3*(-1/4*cos(M)+13/4*cos(3*M))),M=0..2*Pi);
```

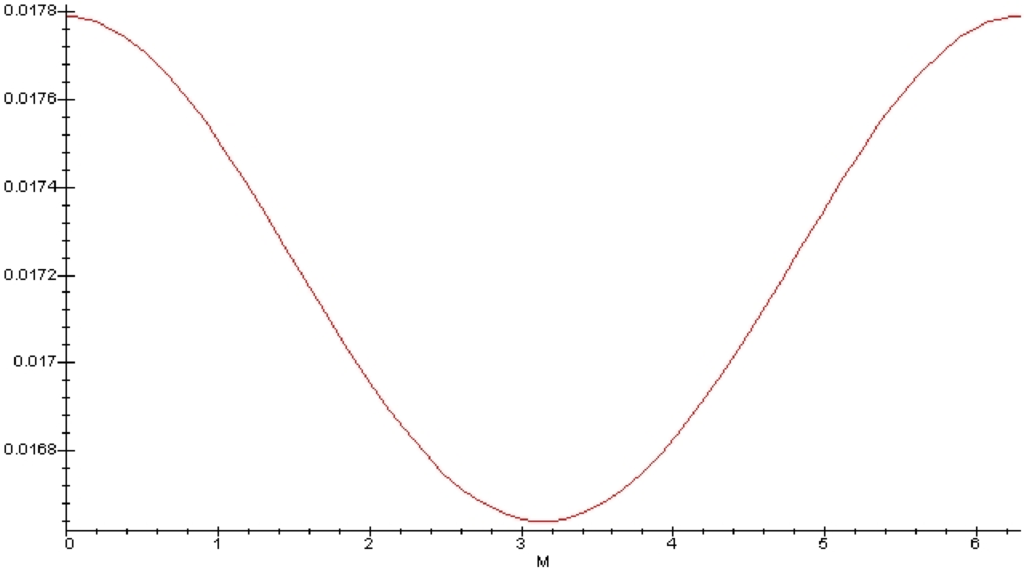


Figure 12.84: Angular velocity of Earth as function of orbits' angle (left perihelion, middle aphelion)

12.1.10.2 Obliquity (inclined plane of the ecliptic) and Sun anomaly

Since the equation of time is to be examined during a year, the Earth can be supposed to always have the same direction in space, i.e., we will not take into account precession and nutation (as their variation during a year is negligible!).

We can describe the direction of the axis of the Earth with two angles. The first is the angle between the axis and the norm of the orbit denoted (ε) and commonly named Earth's obliquity as we already know it. The second is the angle P formed by the major axis of the orbit and the projection of the axis of the Earth onto the plane of the orbit (we don't know if this angle has an official name!):

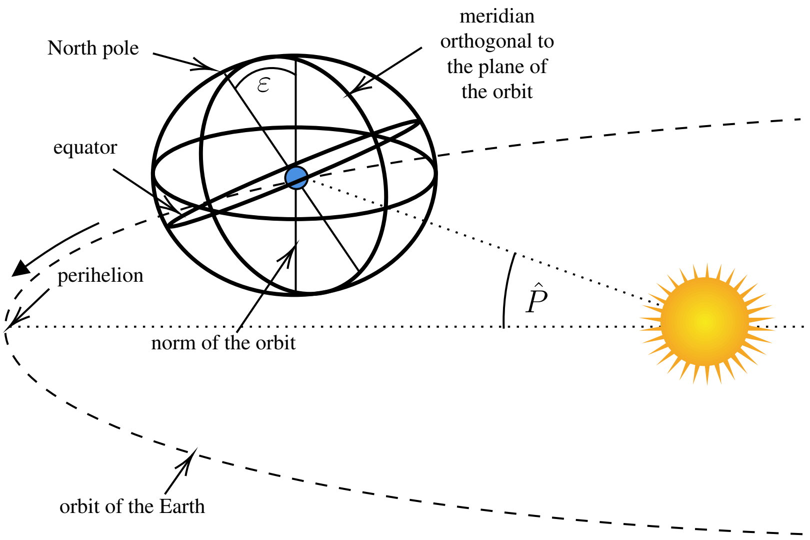

Figure 12.85: The angle $\hat{P}$ and the inclination of the axis of the earth at the winter solstice (not to scale)

At present, ε measures about 23.45°, $\hat{P}$ is about 12.25° ($\hat{P}$ is also the angle which is covered by the Earth between the beginning of winter (21st December) and the arrival of the Earth at perihelion (2nd January) and named the "solar anomaly" or also "perihelion precession angle").

Remark

Remember that the winter solstice and the perihelion are both astronomical events, but they relate to different aspects of Earth's movement. Indeed, the winter solstics marks the shortest day and longest night of the year in a given atmosphere, it's the moment when one of Earth's pole is tilted the farthest away from the Sun. While the perihelion refers to the point in Earth's elliptical orbit when it is closest to the Sun.

The angles which the Sun appears to cover relative to the Earth are equal to those the Earth actually covers relative to the sun. Since the corresponding angles parallel to the equatorial plane are needed for the measurement of time, the ecliptical angles have to be projected onto the equatorial plane. This results in angle widening or shortening. For an infinitesimally small angle the projection factor (the deformation factor) is determined by the angle parameters φ and ε visible in the figure below:

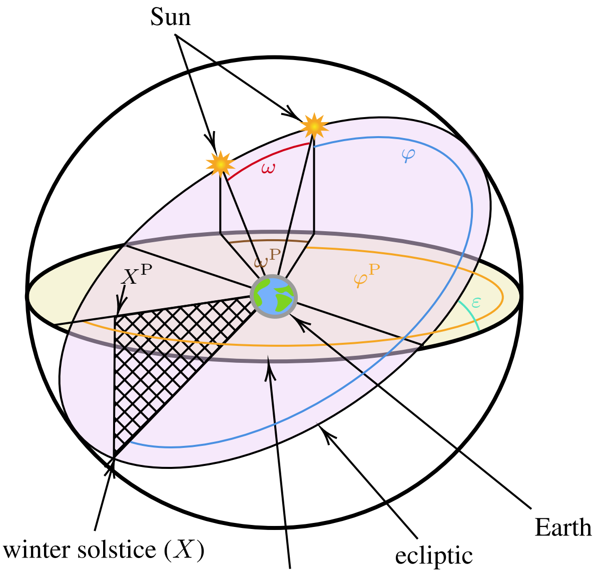

Figure 12.86: **Geocentric view of the projection where in a short time interval, the Sun has covered the angle ω (ω^p is the orthogonal projection of ω)**

which represents the geocentric view. φ is cleverly measured from the winter solstice to force the Sun anomaly to appear in our final result!

We get the following relation from the figure above if the radius are quite huge:

$$\cos(\varepsilon) \cong \frac{\tan(\varphi)}{\tan(\varphi^{\mathrm{P}})} \tag{12.1.633}$$

Hence:

$$\tan(\varphi) \cong \cos(\varepsilon)\tan(\varphi^{\mathrm{P}}) \tag{12.1.634}$$

By extension:

$$\tan(\varphi+\omega) \cong \cos(\varepsilon)\tan\left(\varphi^{\mathrm{P}}+\omega^{\mathrm{P}}\right) \tag{12.1.635}$$

From the two previous relations we have:

$$\varphi^{\mathrm{P}} \cong \arctan\left(\frac{\tan(\varphi)}{\cos(\varepsilon)}\right) \tag{12.1.636}$$

and:

$$\omega^{\mathrm{P}} \cong \arctan\left(\frac{\tan(\varphi+\omega)}{\cos(\varepsilon)}\right) - \varphi^{\mathrm{P}} \tag{12.1.637}$$

Hence combining both:

$$\omega^{\mathrm{P}} \cong \arctan\left(\frac{\tan(\varphi+\omega)}{\cos(\varepsilon)}\right) - \arctan\left(\frac{\tan(\varphi)}{\cos(\varepsilon)}\right) \tag{12.1.638}$$

The projection factor F_p for a small angle can be calculated as a function of φ and ε :

$$F_p(\varphi) \cong \lim_{\omega\rightarrow 0}\frac{\omega^{\mathrm{p}}}{\omega} = \lim_{\omega\rightarrow 0}\frac{\arctan\left(\frac{\tan(\varphi+\omega)}{\cos(\varepsilon)}\right) - \arctan\left(\frac{\tan(\varphi)}{\cos(\varepsilon)}\right)}{\omega} = \frac{\mathrm{d}\omega^{\mathrm{p}}}{\mathrm{d}\omega} \tag{12.1.639}$$

Here we recognize the same relation as in 12.1.572 (but with $alpha$ instead of ε). And we have proved earlier above at 12.1.604 that the latter has an approximation which converges very quickly given by:

$$\begin{aligned} F_p(\varphi) &\cong \frac{\mathrm{d}\omega^{\mathrm{p}}}{\mathrm{d}\omega} \cong 1+2\sum_{k=1}^{+\infty}\tan^{2k}\left(\frac{\alpha}{2}\right)\cos(2kx) \\ &= 1+2\tan^2\left(\frac{\varepsilon}{2}\right)\cos(2\varphi)+2\tan^4\left(\frac{\varepsilon}{2}\right)\cos(4\varphi)+2\tan^6\left(\frac{\varepsilon}{2}\right)\cos(6\varphi)+\ldots \end{aligned} \tag{12.1.640}$$

The projection factor F_p is plotted as a function of time:

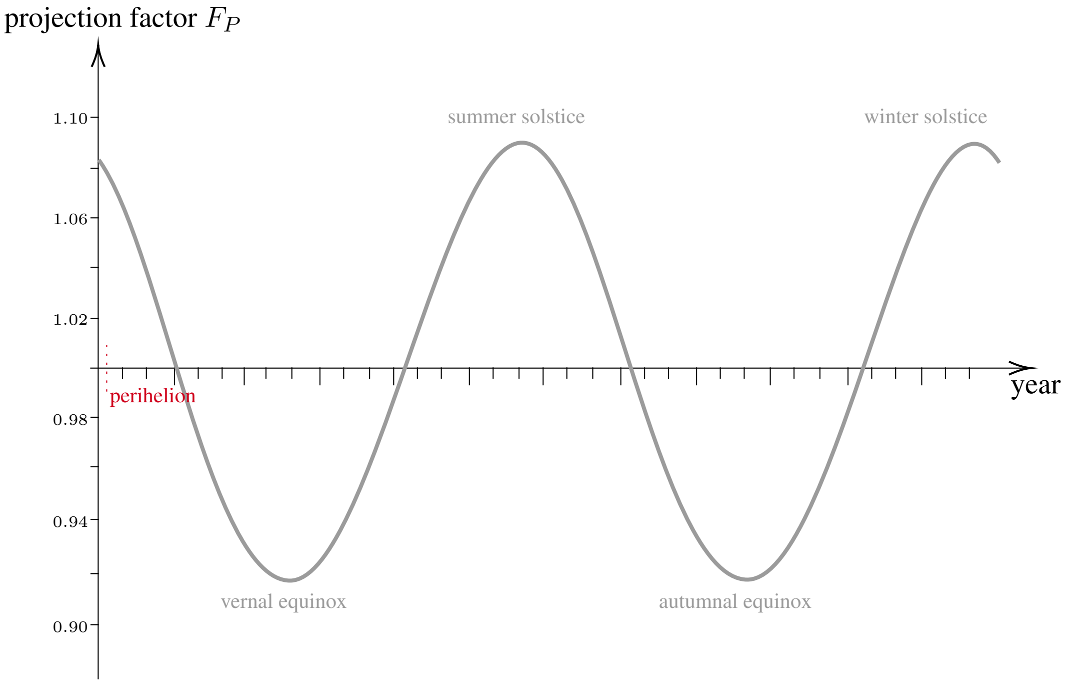

Figure 12.87: **The projection factor as a function of time (the maxima are at the solstices the minima at the equinoxes)**

This graph resembles a cosine function since it is mainly determined by the first variable term of the approximation. The amplitude of the variation $(2\tan^2(\varepsilon/2))$ amounts to $8^1/_2\%$.

The extremes are situated at the beginning of the seasons. At the summer and winter solstice, the Sun reaches, respectively, its highest and lowest position. Here, an ecliptic angle is stretched maximally. At the vernal and autumnal equinox, the Sun stands vertically above the equator. Here, ecliptic angles are shortened maximally.

12.1.10.3 Calculation of the Equation of Time

In order to calculate the equation of time we need the projection of the true anomaly R^{P} as a function of time.

So we write:

$$\hat{R}^{\mathrm{P}}(t)=\int \mathrm{d}R^{\mathrm{P}}=\int f(\varphi)\mathrm{d}R \tag{12.1.641}$$

As by construction we have $\varphi=\hat{R}+\hat{P}$ that is to say the true anomaly plus the Sun anomaly, therefore the above can be rewritten:

$$\begin{aligned}\hat{R}^{\mathrm{P}}(t)=\int\limits_0^t \mathrm{d}\hat{R}^{\mathrm{P}}=\int\limits_0^t f(\hat{R}+\hat{P})\mathrm{d}\hat{R}\cong\int\left[1+2\sum_{i=1}^{+\infty}\tan^{2k}\left(\frac{\varepsilon}{2}\right)\cos(2k(\hat{R}+\hat{P}))\right]\mathrm{d}\hat{R}\\ =\left\{\hat{R}(t)+\sum_{i=1}^{+\infty}\frac{1}{k}\tan^{2k}\left(\frac{\varepsilon}{2}\right)\sin(2k(\hat{R}(t)+\hat{P}))\right\}\\ -\left\{\hat{R}(0)+\sum_{i=1}^{+\infty}\frac{1}{k}\tan^{2k}\left(\frac{\varepsilon}{2}\right)\sin(2k(\hat{R}(0)))\right\}\end{aligned} \tag{12.1.642}$$

By construction we have $\hat{R}(0)=0$ (and don't forget that at the human scale we assume $\hat{P}$ as constant), therefore:

$$\begin{aligned}\hat{R}^{\mathrm{P}}(t)\cong\int\limits_0^t \mathrm{d}\hat{R}^{\mathrm{P}}\\ =\left\{\hat{R}(t)+\sum_{i=1}^{+\infty}\frac{1}{k}\tan^{2k}\left(\frac{\varepsilon}{2}\right)\sin(2k(\hat{R}(t)+\hat{P}))\right\}-\sum_{i=1}^{+\infty}\frac{1}{k}\tan^{2k}\left(\frac{\varepsilon}{2}\right)\sin(2k\hat{P})\end{aligned} \tag{12.1.643}$$

If we put the actual real values ($\varepsilon\cong 23.45°$, $\hat{P}\cong 12.25°$) into the last term and compute it with a specialized software like Maple™ we get:

$$\sum_{i=1}^{+\infty}\frac{1}{k}\tan^{2k}\left(\frac{\varepsilon}{2}\right)\sin(2k\hat{P})\cong 0.01859\cong 1.065° \tag{12.1.644}$$

So we will neglect this constant for the next developments. Hence:

$$\hat{R}^{\mathrm{P}}(t)\cong\hat{R}(t)+\sum_{i=1}^{+\infty}\frac{1}{k}\tan^{2k}\left(\frac{\varepsilon}{2}\right)\sin(2k(\hat{R}(t)+\hat{P})) \tag{12.1.645}$$

To simplify the notation let us get rid of the explicit time dependence:

$$\hat{R}^{\mathrm{P}}\cong\hat{R}(t)+\sum_{i=1}^{+\infty}\frac{1}{k}\tan^{2k}\left(\frac{\varepsilon}{2}\right)\sin(2k(\hat{R}+\hat{P})) \tag{12.1.646}$$

Let us replace $\hat{R}$ by its explicit expression (see page 5418):

$$\hat{R} \cong \hat{M} + 2e\sin(\hat{M}) + \frac{5}{4}e^2\sin(2\hat{M}) + e^3\left(-\frac{1}{4}\sin(\hat{M}) + \frac{13}{12}\sin(3\hat{M})\right) + e^4\ldots \tag{12.1.647}$$

Thus, $\hat{R}^{\text{p}}$ becomes a function of $\hat{M}$:

$$\begin{aligned}\hat{R}^{\text{P}} \cong\ & \hat{M} + 2e\sin(\hat{M}) + \frac{5}{4}e^2\sin(2\hat{M}) + e^3\left(-\frac{1}{4}\sin(\hat{M}) + \frac{13}{12}\sin(3\hat{M})\right) + \ldots\\ & + \tan^2\left(\frac{\varepsilon}{2}\right)\sin\left\{2(\hat{M}+\hat{P}) + 2\left[2e\sin(\hat{M}) + \frac{5}{4}e^2\sin(2\hat{M})\right.\right.\\ & \left.\left. + e^3\left(-\frac{1}{4}\sin(\hat{M}) + \frac{13}{12}\sin(3\hat{M})\right) + \ldots\right]\right\}\\ & + \frac{1}{2}\tan^4\left(\frac{\varepsilon}{2}\right)\sin\left\{4(\hat{M}+\hat{P}) + 4\left[2e\sin(\hat{M}) + \frac{5}{4}e^2\sin(2\hat{M})\right.\right.\\ & \left.\left. + e^3\left(-\frac{1}{4}\sin(\hat{M}) + \frac{13}{12}\sin(3\hat{M})\right) + \ldots\right]\right\}\\ & + \frac{1}{3}\tan^6\left(\frac{\varepsilon}{2}\right)\sin\left\{6(\hat{M}+\hat{P}) + 6\left[2e\sin(\hat{M}) + \frac{5}{4}e^2\sin(2\hat{M})\right.\right.\\ & \left.\left. + e^3\left(-\frac{1}{4}\sin(\hat{M}) + \frac{13}{12}\sin(3\hat{M})\right) + \ldots\right]\right\} + \ldots\end{aligned} \tag{12.1.648}$$

As e is small for the Earth-Sun system let us consider that we can neglect all terms greater than e^2. Therefore it remains:

$$\begin{aligned}\hat{R}^{\text{P}} \cong\ & \hat{M} + 2e\sin(\hat{M}) + \frac{5}{4}e^2\sin(2\hat{M})\\ & + \tan^2\left(\frac{\varepsilon}{2}\right)\sin\left\{2(\hat{M}+\hat{P}) + 2\left[2e\sin(\hat{M}) + \frac{5}{4}e^2\sin(2\hat{M})\right]\right\}\\ & + \frac{1}{2}\tan^4\left(\frac{\varepsilon}{2}\right)\sin\left\{4(\hat{M}+\hat{P}) + 4\left[2e\sin(\hat{M}) + \frac{5}{4}e^2\sin(2\hat{M})\right]\right\}\\ & + \frac{1}{3}\tan^6\left(\frac{\varepsilon}{2}\right)\sin\left\{6(\hat{M}+\hat{P}) + 6\left[2e\sin(\hat{M}) + \frac{5}{4}e^2\sin(2\hat{M})\right]\right\} + \ldots\end{aligned} \tag{12.1.649}$$

Let us distribute:

$$\begin{aligned}\hat{R}^{\text{P}} \cong\ & \hat{M} + 2e\sin(\hat{M}) + \frac{5}{4}e^2\sin(2\hat{M})\\ & + \tan^2\left(\frac{\varepsilon}{2}\right)\sin\left\{2(\hat{M}+\hat{P}) + 4e\sin(\hat{M}) + \frac{5}{2}e^2\sin(2\hat{M})\right\}\\ & + \frac{1}{2}\tan^4\left(\frac{\varepsilon}{2}\right)\sin\left\{4(\hat{M}+\hat{P}) + 8e\sin(\hat{M}) + 5e^2\sin(2\hat{M})\right\}\\ & + \frac{1}{3}\tan^6\left(\frac{\varepsilon}{2}\right)\sin\left\{6(\hat{M}+\hat{P}) + 12e\sin(\hat{M}) + 15e^2\sin(2\hat{M})\right\} + \ldots\end{aligned} \tag{12.1.650}$$

Let us focus on the first brace. Using trigonometric identities (see section Trigonometry page 2519), we get:

$$\begin{aligned}\sin\left(2(\hat{M}+\hat{P})+4e\sin(\hat{M})+\frac{5}{2}e^2\sin(2\hat{M})\right)=&\sin(2(\hat{M}+\hat{P}))\cdot\cos(4e\sin(\hat{M}))\cdot\cos\left(\frac{5}{2}e^2\sin(2\hat{M})\right)\\&+\cos(2(\hat{M}+\hat{P}))\cdot\sin(4e\sin(\hat{M}))\cdot\cos\left(\frac{5}{2}e^2\sin(2\hat{M})\right)\\&+\cos(2(\hat{M}+\hat{P}))\cdot\cos(4e\sin(\hat{M}))\cdot\sin\left(\frac{5}{2}e^2\sin(2\hat{M})\right)\\&-\sin(2(\hat{M}+\hat{P}))\cdot\sin(4e\sin(\hat{M}))\cdot\sin\left(\frac{5}{2}e^2\sin(2\hat{M})\right)\end{aligned}\tag{12.1.651}$$

For the trigonometric factor involving e, we can use the Maclaurin approximation (see section Sequences and Series page 1703):

$$\sin(x)=x\qquad\cos(x)=1-\frac{1}{2}x^2\tag{12.1.652}$$

Hence:

$$\begin{aligned}\sin\left(2(\hat{M}+\hat{P})+4e\sin(\hat{M})+\frac{5}{2}e^4\sin(2\hat{M})\right)=&\sin(2(\hat{M}+\hat{P}))\cdot(1-8e^2\sin^2(\hat{M}))\cdot\left(1-\frac{25}{8}e^2\sin^2(2\hat{M})\right)\\&+\cos(2(\hat{M}+\hat{P}))\cdot4e\sin(\hat{M})\cdot\left(1-\frac{25}{4}e^4\sin(2\hat{M})\right)\\&+\cos(2(\hat{M}+\hat{P}))\cdot(1-8e^2\sin^2(\hat{M}))\cdot\frac{5}{2}e^2\sin(2\hat{M})\\&-\sin(2(\hat{M}+\hat{P}))\cdot4e\sin(\hat{M})\cdot\frac{5}{2}e^2\sin(2\hat{M})\end{aligned}\tag{12.1.653}$$

and let us ignore power of e greater than 2, therefore:

$$\begin{aligned}\sin\left(2(\hat{M}+\hat{P})+4e\sin(\hat{M})+\frac{5}{2}e^2\sin(2\hat{M})\right)=&\sin(2(\hat{M}+\hat{P}))\cdot(1-8e^2\sin^2(\hat{M}))\\&+\cos(2(\hat{M}+\hat{P}))\cdot4e\sin(\hat{M})\\&+\cos(2(\hat{M}+\hat{P}))\cdot(1-8e^2\sin^2(\hat{M}))\cdot\frac{5}{2}e^2\sin(2\hat{M})\\&-\sin(2(\hat{M}+\hat{P}))\cdot4e\sin(\hat{M})\cdot\frac{5}{2}e^2\sin(2\hat{M})\end{aligned}\tag{12.1.654}$$

Expanding gets us here:

$$\sin(2(\hat{M}+\hat{P}))+4e\cos(2(\hat{M}+\hat{P}))\sin(\hat{M}))+e^2\left(-8\sin(2(\hat{M}+\hat{P})\sin^2(\hat{M})+\frac{5}{2}\cos(2(\hat{M}+\hat{P}))\sin(2\hat{M})\right)\tag{12.1.655}$$

Doing similarly for all other braces, we get:

$$
\begin{aligned}
R^{\mathrm{P}} \cong\; & \hat{M}+\tan^2\left(\frac{\varepsilon}{2}\right)\left(1-4e^2\right)\sin(2(\hat{M}+\hat{P}))+2e\sin(\hat{M})\\
& -2e\tan^2\left(\frac{\varepsilon}{2}\right)\sin(\hat{M}+2\hat{P})+2e\tan^2\left(\frac{\varepsilon}{2}\right)\sin(3\hat{M}+2\hat{P})\\
& +\frac{1}{2}\tan^4\left(\frac{\varepsilon}{2}\right)\sin(4(\hat{M}+\hat{P}))+\frac{5}{4}e^2\sin(2\hat{M})-2e\tan^4\left(\frac{\varepsilon}{2}\right)\sin(3\hat{M}+4\hat{P})\\
& +2e\tan^4\left(\frac{\varepsilon}{2}\right)\sin(5\hat{M}+4\hat{P})+\frac{13}{4}e^2\tan^2\left(\frac{\varepsilon}{2}\right)\sin(4\hat{M}+2\hat{P})+\frac{1}{3}\tan^6\left(\frac{\varepsilon}{2}\right)\sin(6(\hat{M}+\hat{P}))
\end{aligned}
\tag{12.1.656}
$$

The equation of time is defined by:

$$
\begin{aligned}
\text{Equation of Time (EoT)} = \; & \text{"true equatorial Sun angle"}\\
& -\text{"mean equatorial Sun angle" (geocentric view)}\\
= \; & -(\text{ true projected anomaly } - \text{ mean anomaly })\\
& \text{(heliocentric view)}\\
= \; & \hat{M}-\hat{R}^{\mathrm{P}}
\end{aligned}
\tag{12.1.657}
$$

We can finally come to the point. The Equation of Time is by definition the difference between true solar time and mean solar time. For instance, if a mean solar clock shows 3hrs 23min and at the same instant a true solar clock (maybe a sundial) shows 3hrs 31min, then the equation of time at that instant is 8min.

According to our definitions, the equation of time is therefore the difference between the hour angles of the true Sun and the mean Sun. Equivalently, it is the difference between the right ascensions (the celestial equivalent of longitude, measuring the East-West position of an astronomical object on the celestial sphere) of the mean Sun and the true Sun.

Now we can calculate the Equation of Time with the values of the parameters as in the early 121st century (holocene calendar) $\varepsilon=23.45^\circ$ and $e=0.0167$:

$$
\begin{aligned}
\text{EoT} := \hat{M}-\hat{R}^{\mathrm{P}} \cong\; & -0.043215861\sin(2(\hat{M}+\hat{P}))-0.0334\sin(\hat{M})\\
& +0.00144502\sin(\hat{M}+2\hat{P})-0.00144502\sin(3\hat{M}+2\hat{P})\\
& -0.000015629\sin 4(\hat{M}+\hat{P})-0.000348613\sin(2\hat{M})\\
& +0.000062518\sin(3\hat{M}+4\hat{P})-0.000062518\sin(5\hat{M}+4\hat{P})\\
& -0.000039214\sin(4\hat{M}+2\hat{P})-0.000026994\sin 6(\hat{M}+\hat{P})
\end{aligned}
\tag{12.1.658}
$$

If want to convert the angle of EoT in seconds, each coefficient has to be multiplied by:

$$
\frac{24\cdot 60\cdot 60}{2\pi}\cong 13750.987083\,[\mathrm{s}\cdot\mathrm{rad}^{-1}]
\tag{12.1.659}
$$

So we have in seconds:

$$
\begin{aligned}
\text{EoT} \cong\; & -594.2607464\sin(2(\hat{M}+\hat{P}))-459.2829686\sin(\hat{M})\\
& +19.87045135\sin(\hat{M}+2\hat{P})-19.87045135\sin(3\hat{M}+2\hat{P})\\
& -0.214914177\sin 4(\hat{M}+\hat{P})-4.79377286\sin(2\hat{M})\\
& +0.85968421\sin(3\hat{M}+4\hat{P})-0.85968421\sin(5\hat{M}+4\hat{P})\\
& -0.539231207\sin(4\hat{M}+2\hat{P})-0.371194145\sin 6(\hat{M}+\hat{P})\;[\mathrm{s}]
\end{aligned}
\tag{12.1.660}
$$

Or rounded to the nearest first decimal:

$$\begin{aligned}\text{EoT} \cong\, & -594.3\sin(2(\hat{M}+\hat{P}))-459.3\sin(\hat{M})\\ & +19.9\sin(\hat{M}+2\hat{P})-19.9\sin(3\hat{M}+2\hat{P})\\ & -0.2\sin 4(\hat{M}+\hat{P})-4.8\sin(2\hat{M})\\ & +0.9\sin(3\hat{M}+4\hat{P})-0.9\sin(5\hat{M}+4\hat{P})\\ & -0.5\sin(4\hat{M}+2\hat{P})-0.4\sin 6(\hat{M}+\hat{P})\ [\text{s}]\end{aligned} \tag{12.1.661}$$

keeping in mind that in the early 121st century we have the angle $\hat{P}$ that measures about $12.25°$.

The equation of time, and therefore the analemma, is determined by the three following parameters in the case of a non-relativistic and stable orbit:

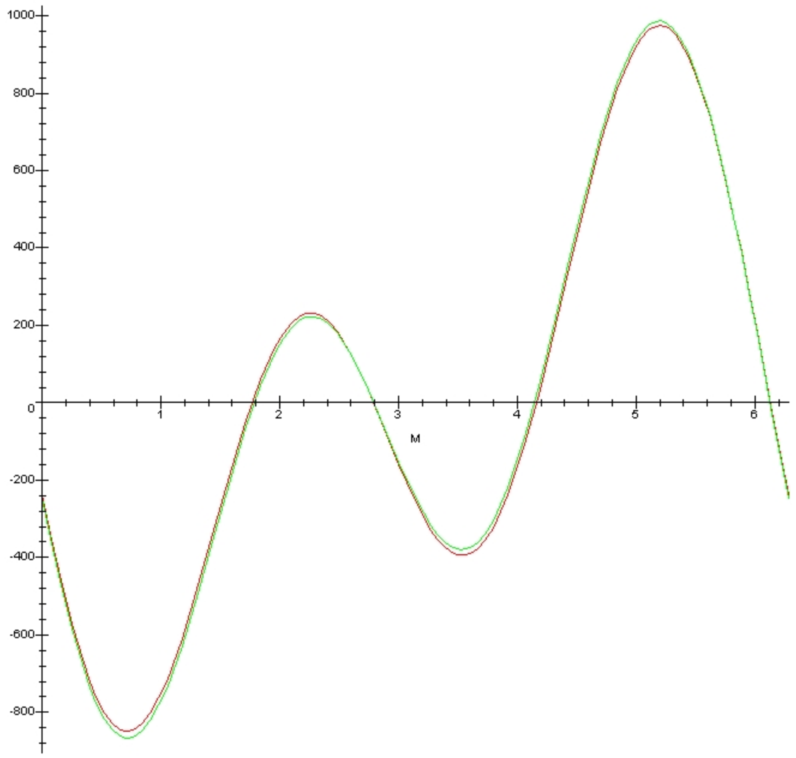
- The eccentricity e of the orbit of the Earth
- The angle between the ecliptic and the equatorial planes ε.
- The angle $\hat{P}$ between the winter solstice and the perihelion relative to the Sun (i.e. the time span Δt from the beginning of winter to the passage through the perihelion)

The last two parameters change gradually by nutation and precession!

Thus, if either of these variables (such as eccentricity) always dominates the other (as is the case on Mars), the analemma will resemble a teardrop. If either of the variables (such as eccentricity) is significant, and the other is practically zero (as is the case on Jupiter, with only a $3°$ tilt), the figure will be something much closer to an ellipse. If both are important enough, that sometimes eccentricity or axial tilt dominates, a figure-eight results.

A plot in Maple™ 4.00b of the above relation shows that if we take the first two terms or the firs three, the difference is negligible:

```
>P:=evalf((12.25/360)*(2*Pi));
>plot([-594.3*sin(2*(M+P))-459.3*sin(M)+19.9*sin(M+2*P),-594.3*sin(2*(M+P))
-459.3*sin(M)],M=0..2*Pi);
```



As we can see the true solar time can deviate from the mean solar time up to approximately 16 minutes. This explains why sundials that give the true solar time differ most of the time from the time visible on your watch (the latter giving a political business time that exists only for convenience).

That's why it is common to find the equation of time as defined as:

$$\boxed{\text{Equation of Time} \cong -594.3\sin(2(\hat{M}+\hat{P})) - 459.3\sin(\hat{M})\;[\text{s}]} \tag{12.1.662}$$

where for reminder:

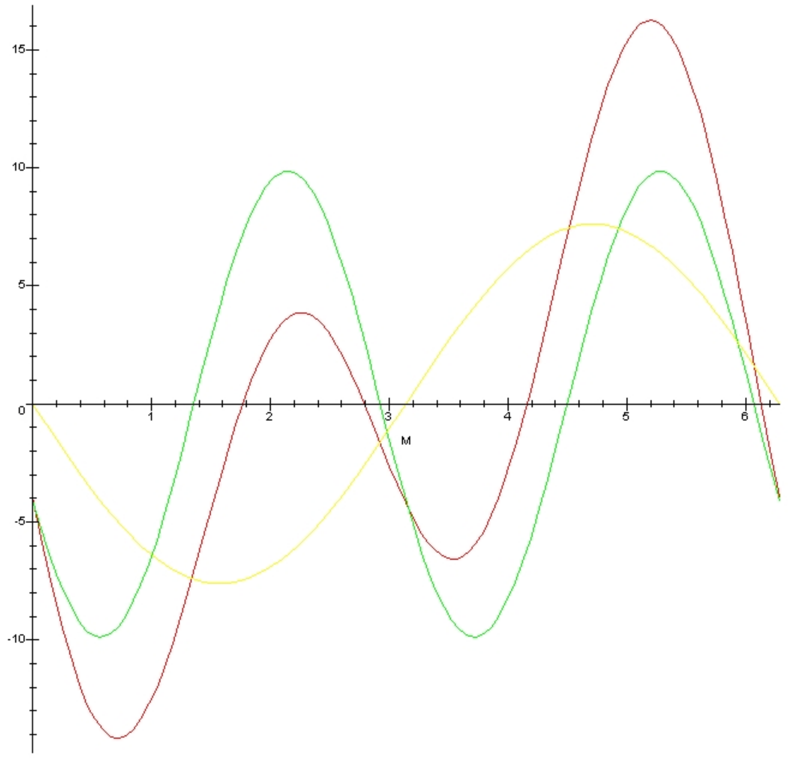
$$\hat{M} = 2\pi\frac{t}{T} \tag{12.1.663}$$

Or in minutes with the common abbreviation and in minutes instead of seconds:

$$\text{EoT} \cong -9.9\sin(2(\hat{M}+\hat{P})) - 7.65\sin(\hat{M})\;[\text{min}] \tag{12.1.664}$$

The graph of the equation of time is closely approximated by the sum of two sine curves, one with a period of a year and one with a period of half a year. The curves reflect two astronomical effects, each causing a different non-uniformity in the apparent daily motion of the Sun relative to the stars:

- The obliquity of the ecliptic
- The eccentricity of the Earth's orbit around the Sun



The diagram below represents the equation of time as a function of the day of the year (divide by 10 such that the day 350 for example is equal to 35), starting at the perigee (the black curve):

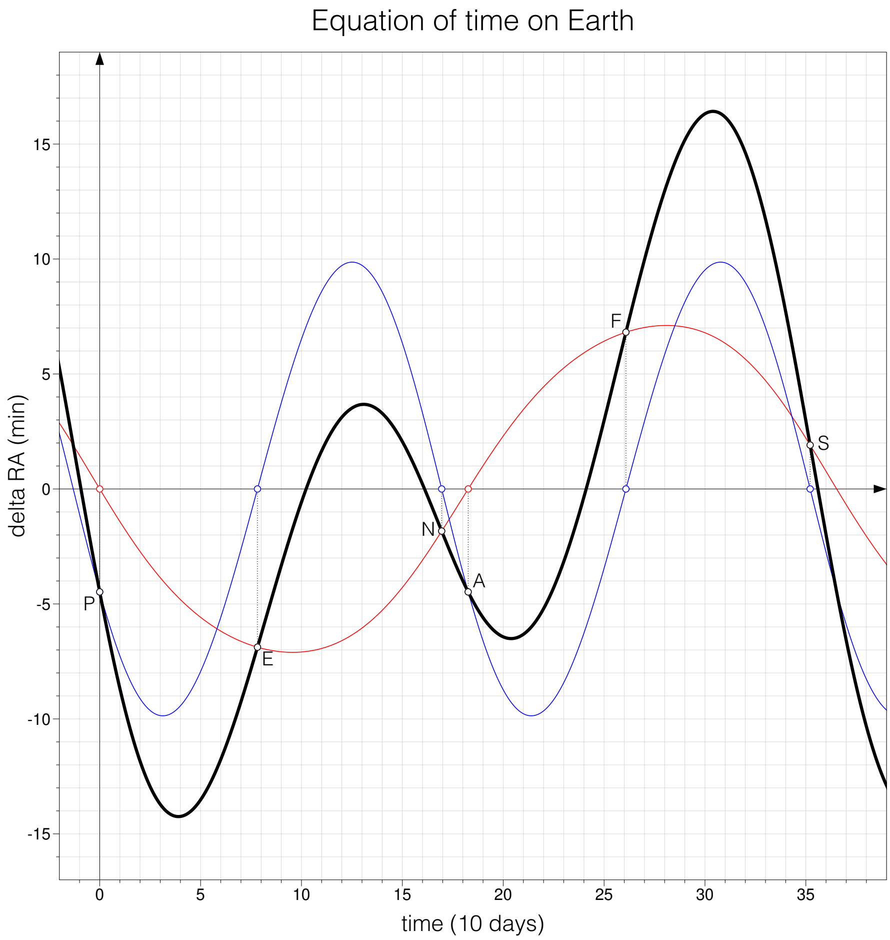


Figure 12.88: **Equation of time on Earth**
(author: Pierre Barbier, source: https://pbarbier.com/eqtime/eqtime.html**)**

The other curves represent the individual contributions of the obliquity (the difference between "uniform solar time" and mean solar time, in blue), and the eccentricity of the orbit (the difference between true solar time and uniform solar time, in red). The ordinate of every point on the black curve is the sum of the ordinates of the points on the other curves at the same abscissa.

The special points on the curves mark the situations:

- At the perigee (P) and apogee (A), where the true and uniform suns coincide and there is no difference between true and uniform solar times
- At the equinoctial points, vernal (E) and autumnal (F), where the uniform and mean suns coincide and there is no difference between uniform and mean solar times
- At the north (N) and south (S) solstitial points where the uniform and mean suns coincide again and there is no difference between uniform and mean solar times.

Note that the instants corresponding to the points (E) (F) (N) (S) are the times of passage of the uniform Sun at the equinoctial and solstitial points on the relative orbit of the sun. The true Sun does not necessarily pass through these points at exactly the same time.

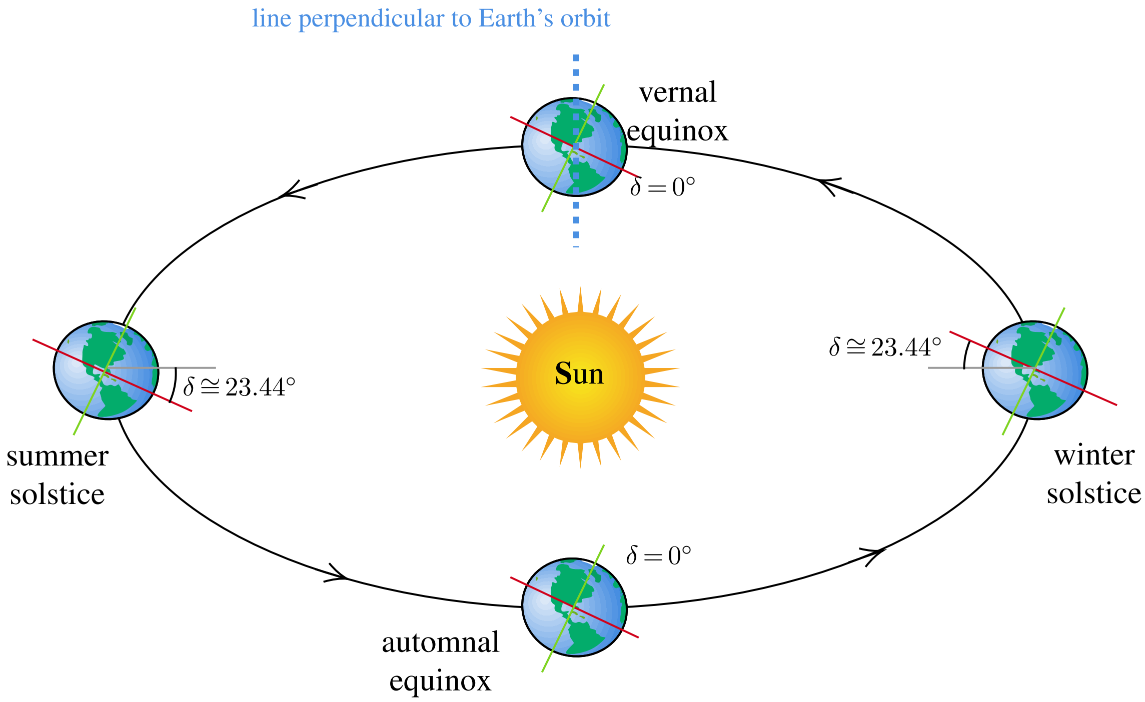
Now to get the analemma, we have to plot the equation of time in function of the declination (angular distance of a celestial body North (+) or South (−) from the celestial equator). Indeed by definition the analemma is the curve obtained by plotting the equation of time as the horizontal coordinate against the declination of the (true) Sun as the vertical coordinate.

Let us first remind that the declination is the angular distance of a celestial object North or South of the celestial equator. The "declination" is given by (the number 10 offset accounts for the fact that the winter solstice - when declination is at its minimum - occurs before the beginning of the year):

$$\boxed{\delta \cong -23.45^\circ \cdot \cos\left(\frac{360}{365}\cdot(d+10)\right)} \tag{12.1.665}$$

where d is the day of the year with January 1 as $d=1$ and the content of the parenthesis of the $\cos$ must not be forgotten to be converted into radians to get the right result!

The declination is zero at the equinoxes (March 22 and September 22), positive during the northern hemisphere summer and negative during the northern hemisphere winter. The declination reaches a maximum of 23.45° on June 22 (summer solstice in the northern hemisphere) and a minimum of -23.45° on December 21-22 (winter solstice in the northern hemisphere). In the relation above, the $+10$ comes from the fact that the winter solstice occurs before the start of the year. The equation also assumes that the Sun orbit is a perfect circle (hence the approximation sign $\cong$) and the factor of $360/365$ converts the day number to a position in the orbit.



Remark

The detailed derivation of the declination angle assumes a circular orbit and gives the following result:

$$\sin(\delta) = \sin(-23.45^\circ)\cos\left(\frac{360}{365}\cdot(d+10)\right) \qquad (12.1.666)$$

In radians, $\alpha \cong \sin(\alpha)$, for small values of δ so the derivation reduces to the approximation:

$$\delta \cong -23.45^\circ \cos\left(\frac{360}{365}\cdot(d+10)\right) \qquad (12.1.667)$$

The difference between the two equations is very small ($< 0.3^\circ$), whereas the error to the true declination. Thus the simpler equation is preferred since it is acceptable for common civil usage.

The equalities:

$$\begin{aligned}\delta &\cong 23.45^\circ \cdot \sin\left(\frac{360}{365}\cdot(d+284)\right)\\ \delta &\cong 23.45^\circ \cdot \sin\left(\frac{360}{365}\cdot(d-81)\right)\end{aligned} \qquad (12.1.668)$$

are also often used in the literature. They are referred to the equinoxes instead so use $\sin$ instead of $\cos$.

Finally, there are many algorithms for more accurate determinations of declination angle to account for the elliptic and yearly movement of the Earth's orbit based on Fourier series.

The various ways of calculating the declination angle are graphed below using Python™ code:

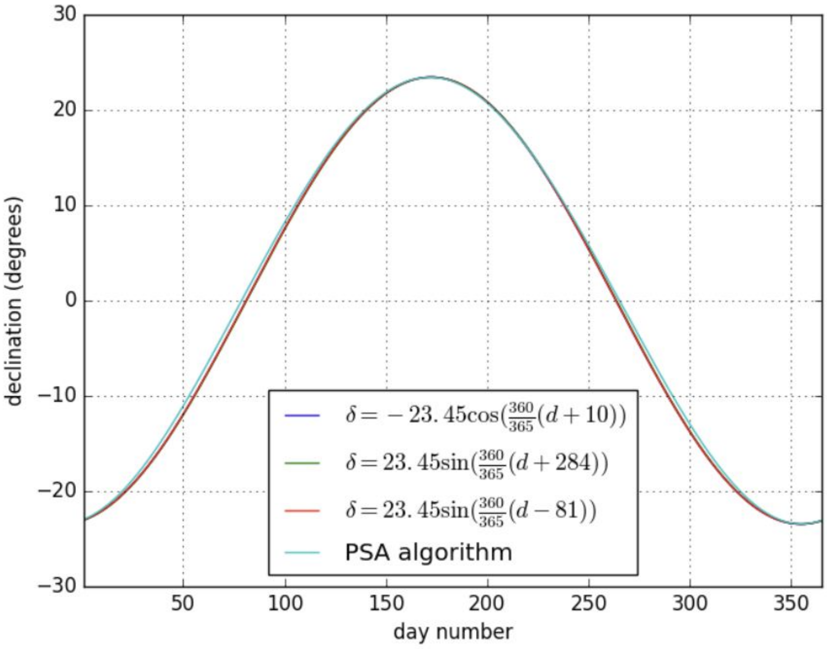


Figure 12.89: Various declination calculation methods compared (authors: Christiana Honsberg and Stuart Bowden)

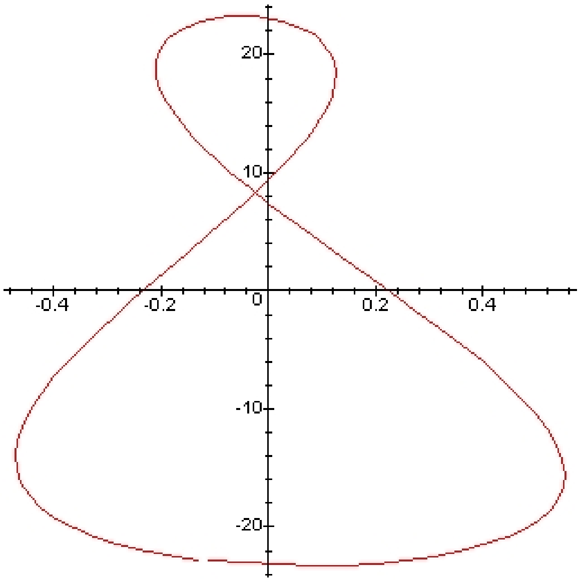
Hence in Maple™ 4.00b we have:

```
>epsilon:=23.45/360*2*Pi;
>P:=12.25/360*2*Pi;
>e:=0.0167;
>EOT:=-(tan(epsilon/2))^2*(1-4*e^2)*sin(2*(2*Pi*t/365+P))-2*e*sin(2*Pi*t/365);
>Declination:=0.4059*cos((360/365)/360*2*Pi*(t+10));
>plot([EOT,-Declination/Pi*180,t=0..365]);
```



The analemma is the curve obtained by plotting the equation of time as the x coordinate against the declination of the (true) Sun as the y coordinate:

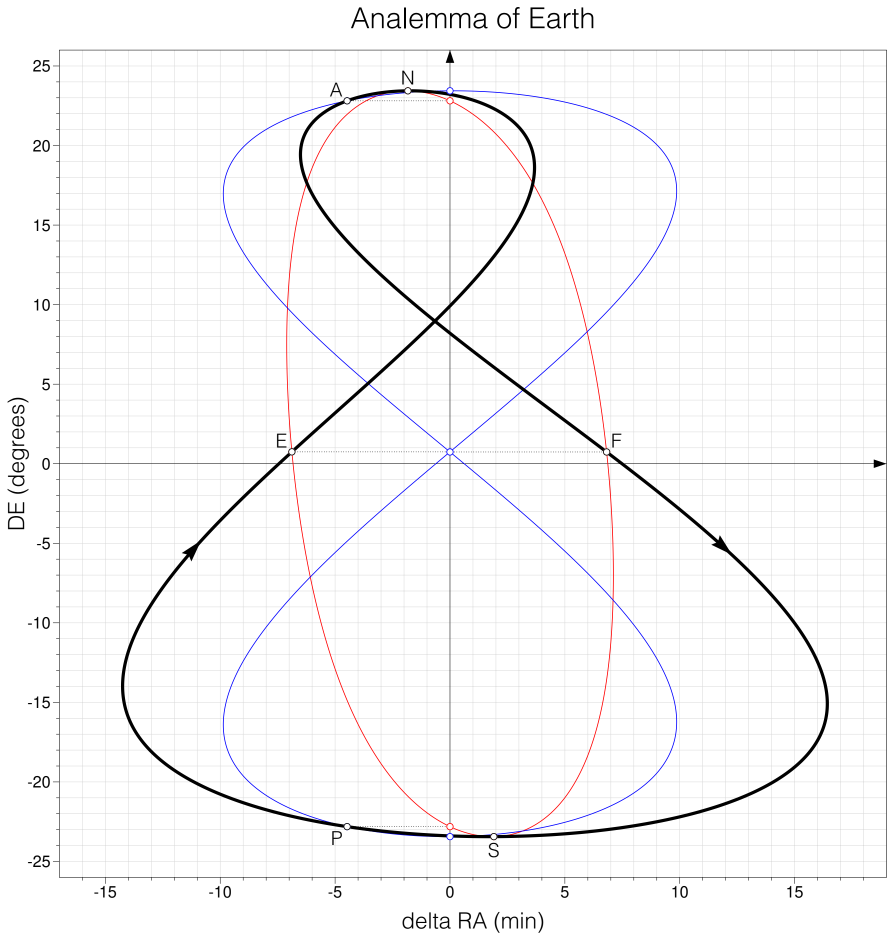


Figure 12.90: **Earth analema**
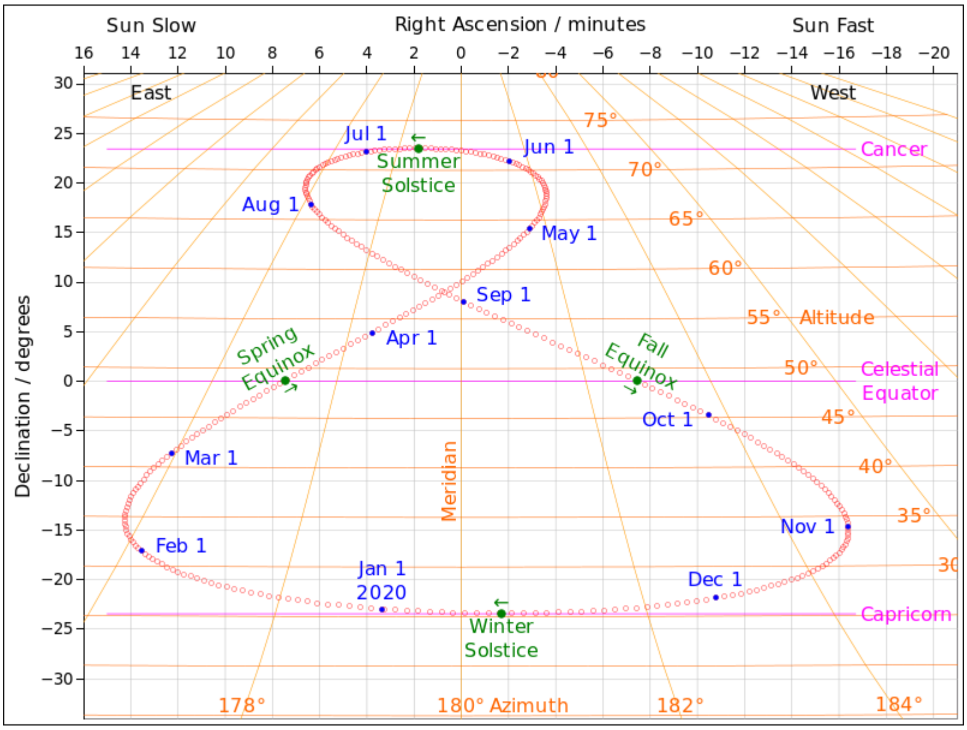
(author: Pierre Barbier, source: `https://pbarbier.com/eqtime/eqtime.html`**)**

At each instant, the declination of the Sun and value of the equation of time correspond to a point on the curve. This point moves along the curve as the Sun moves along the ecliptic, in the direction indicated by the arrow on the black curve, completing a full turn in a year.

Again, the individual contributions of the obliquity (in blue) and the eccentricity (in red) are represented, as well as the situation at the perigee (P), apogee (A), vernal (E) and autumnal (F) points, north (N) and south (S) solstitial points. The abscissa of any point of the black curve is the sum of the abscissas of the points of the blue and red curves at the same ordinate (and chosen on the correct branch of the curve, the one corresponding to the same season, since in most cases two abscissas correspond to the same ordinate on each curve).

This particular way of plotting the equation of time makes it convenient to compute mean solar time from the reading on a sundial. The sundial may give the declination of the Sun as the length of the shadow of the stylus, in addition to true solar time. The time correction, the equation of time, can be read directly on the analemma curve at that declination. For this reason, the analemma curve can sometimes be found drawn on the face of sundials.

A more detailed version looks like:



Remark

Where the intersection occurs is a result of the asymmetry of the analemma caused by the difference between the solstice date and perihelion dates.

Another version:

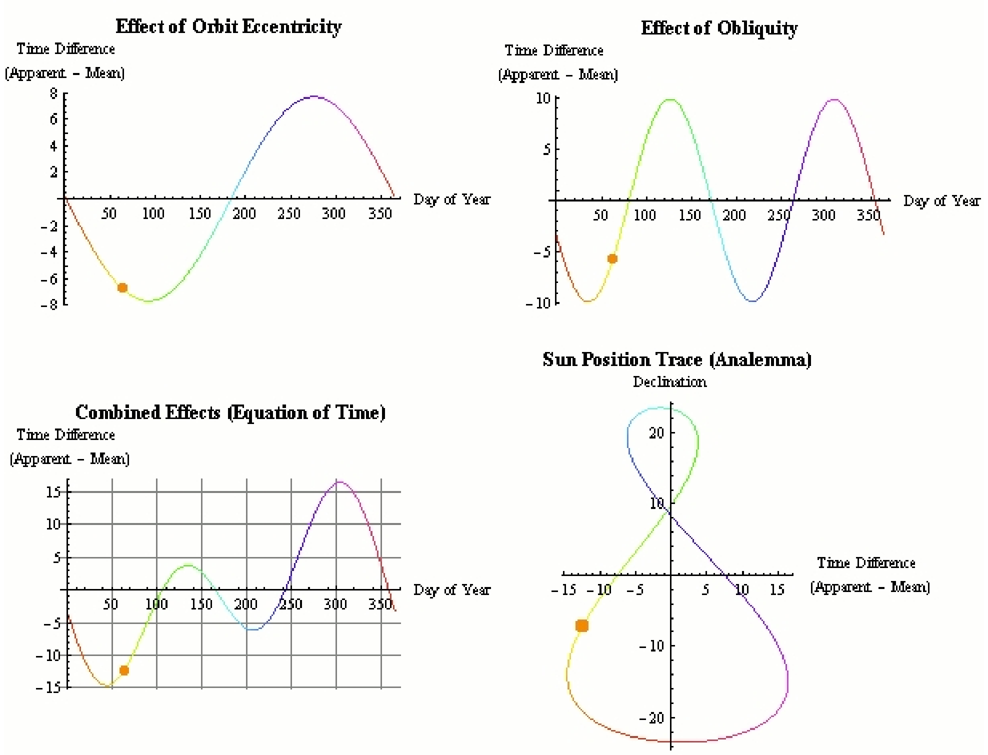


Figure 12.91: Equation of time and analemma correspondence (author: Rob Cook)

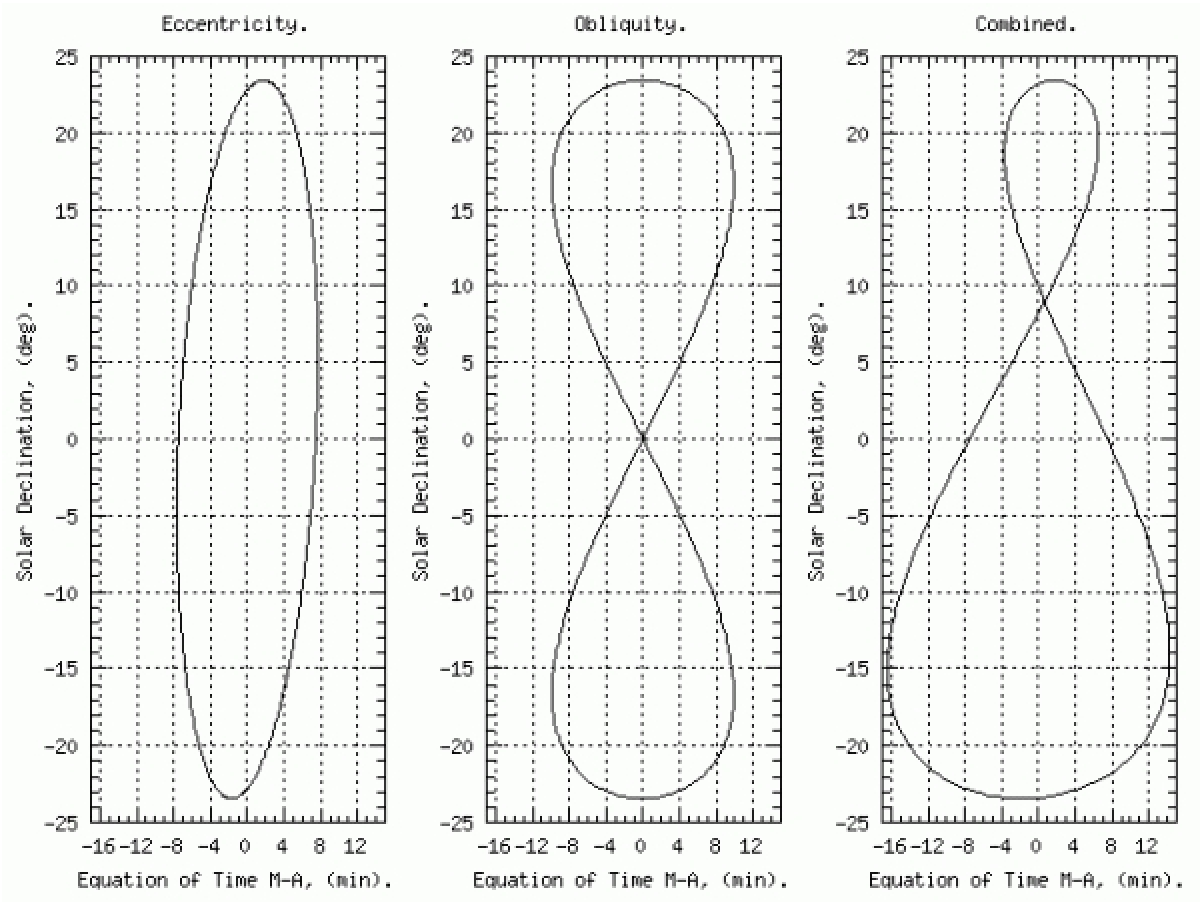
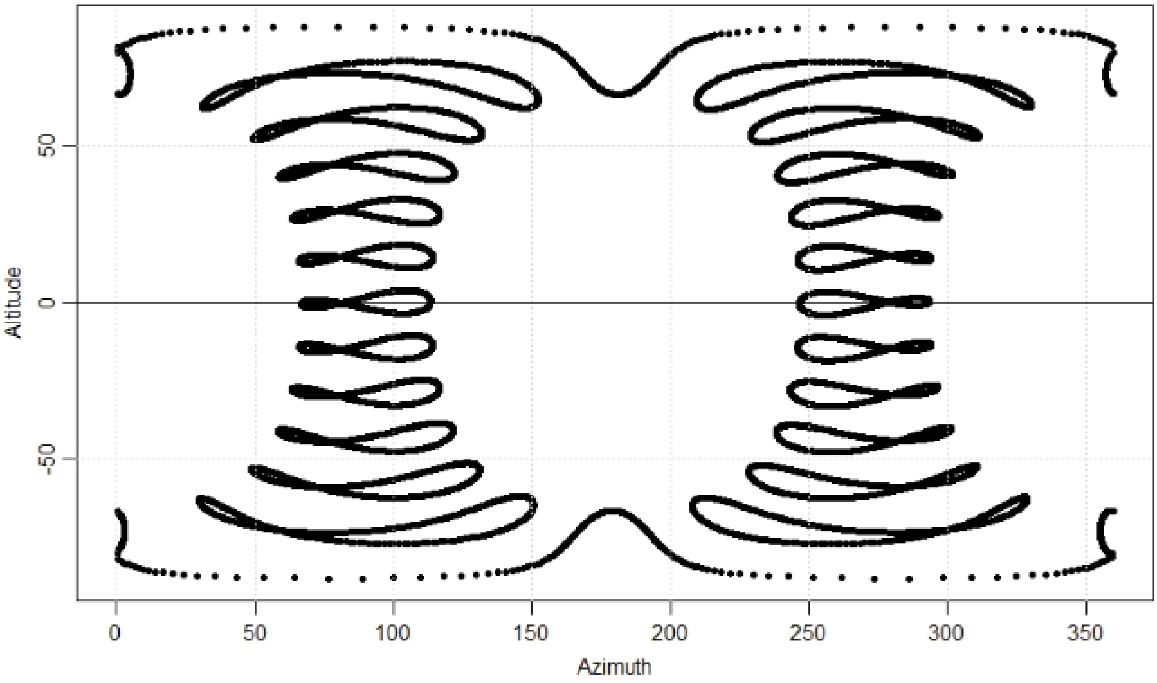
Here is a visual with the different components of the analemma:



Or using the R software (see the corresponding detailed code in the R companion book) we can have the figure of the analemma at different azimuth and altitude:



Obviously our results match with reality because the Earth isn't flat...

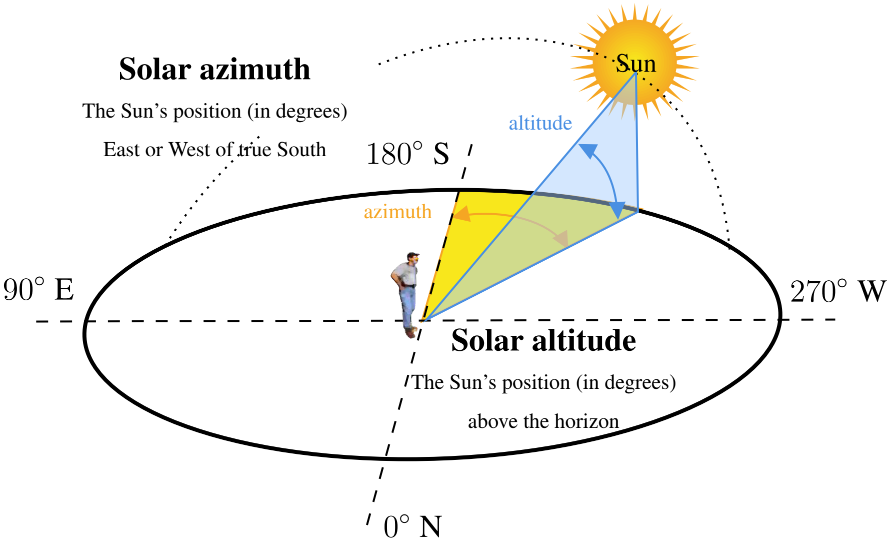
Figure 12.92: **Juxtaposition of theoretical analemma with an observed one**

12.1.11 Sundials

A "sundial" is a horological device that tells the time of day (referred to as civil time in modern usage) when direct sunlight shines by the apparent position of the Sun (actually a G2V-type star, aka yellow dwarf) in the sky. In the narrowest sense of the word, it consists of a flat plate (the dial) and a gnomon (a protruding structure, like a pole or bar), which casts a shadow onto the dial. As the Sun appears to move through the sky, the shadow aligns with different hour-lines, which are marked on the dial to indicate the time of day. The style is the time-telling edge of the gnomon, though a single point or nodus may be used. The gnomon casts a broad shadow; the shadow of the style shows the time. The gnomon may be a rod, wire, or elaborately decorated metal casting. The style must be parallel to the axis of the Earth's rotation for the sundial to be accurate throughout the year. The style's angle from horizontal is equal to the sundial's geographical latitude. If a sundial is to tell the time accurately it must ordinarily be designed for the particular latitude in which it is to be used.

The term sundial can refer to any device that uses the Sun's altitude or azimuth[20] (or both) to show the time. Sundials are valued as decorative objects, metaphors, and objects of intrigue and mathematical study.



Solar azimuth
The Sun's position (in degrees)
East or West of true South

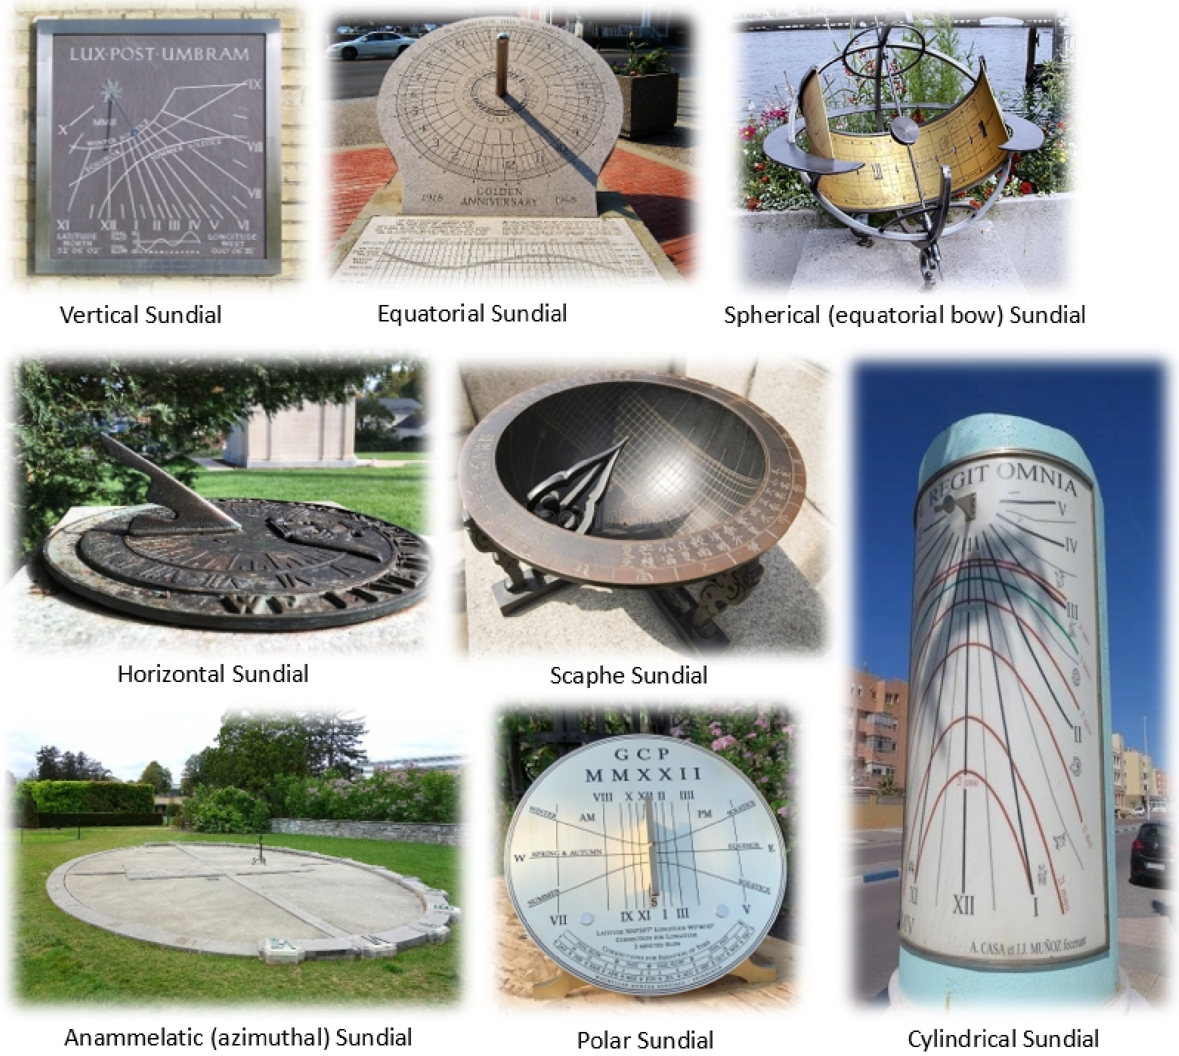
altitude
180° S
azimuth
90° E
270° W
Solar altitude
The Sun's position (in degrees)
above the horizon
0° N

Figure 12.93: **Azimuth and Altitude depicted**

There are several different types of sundials illustrated below:

---

[20] The "azimuth" is the horizontal angle from a cardinal direction, most commonly North, in a local or observer-centric spherical coordinate system. Sadly there seems to be no international standard that defined unequivocally the azimuth to a given cardinal.



Vertical Sundial

Equatorial Sundial

Spherical (equatorial bow) Sundial

Horizontal Sundial

Scaphe Sundial

Anammelatic (azimuthal) Sundial

Polar Sundial

Cylindrical Sundial

Figure 12.94: **Most common type of sundials**

Caution! Most sundials show what is known as "true local time". This differs from the time on your watch, which is named "standard mean time".

Let us give a small description of the most common one:

- The **vertical sundial** is a type of sundial where the dial plate is mounted vertically, often on a wall. It's designed to measure time using the shadow cast by a gnomon. These sundials are commonly found on buildings, especially those facing south named **vertical direct south dials**, and are used to display the time throughout the day.
- The **equatorial sundial** has the advantages that it can be made without mathematical calculation, and, unlike most other sundials, may be used in any latitude if properly set up. It gets it name from the fact that the "dial plate" lies parallel to the Equator. The gnomon is a rod or pin set perpendicular to the dial plate in the center of the dial. This gnomon is parallel to the earth's axis and points toward the north celestial pole, close to the Pole Star.

- The **horizontal sundial** is far more common than all other types combined. Its popularity arise in part from the fact that it tells the time whenever the Sun is shining, while many types of sundials can be used only during restricted hours of the day. In addition horizontal dials are comparatively easy to make and to set into place for use. They make beautiful and appropriate garden ornaments, and even a small garden can well find a spot for one at the end of a pathway or as an accent in a formal flower border.

- The **spherical sundial**, also known as an **armillary sphere** or **spherical astrolabe**, is a type of sundial that uses a spherical framework to display time. It's essentially a model of the celestial sphere with rings representing celestial longitude and latitude. This design allows for the accurate indication of time by the movement of shadows cast by a gnomon positioned within the sphere.

- The **scaphe sundial** is an ancient type of sundial that consists of a hemispherical bowl with a vertical gnomon placed inside it. The shadow of the gnomon moves across the curved surface, allowing time to be read from the hour lines inscribed within the bowl. This design compensates for the non-uniform shadow movement seen on flat sundials, making it a fascinating piece of early astronomical ingenuity.

- The **analemmatic sundial** is a type of horizontal sundial that has a vertical gnomon and hour markers arranged in an elliptical pattern. Unlike traditional sundials, the gnomon in an analemmatic sundial is not fixed - it must be moved daily to account for the changing position of the Sun throughout the year. One funny feature of this sundial is that it can be designed as a "human sundial", where a person stands in place of the gnomon and their shadow indicates the time.

- The **polar sundial** is a unique type of sundial where the dial plate is parallel to the Earth's axis, meaning it's tilted at an angle that matches the observer's latitude. Unlike traditional sundials, its hour lines are evenly spaced and parallel to each other, rather than radiating outward from a central point. The gnomon is also parallel to the dial plate.

- The **vertical cylindrical sundial** is a type of sundial where the hour lines are marked on the outer surface of a vertical cylinder. The gnomon, which casts the shadow, is typically perpendicular to the cylinder's surface and can be oriented in different directions depending on the design.

The mathematical proofs and development that follow are almost a copy/paste of the excellent article *The mathematics of sundials* (see [562]) from PhD Jill Vincent (university of Melbourne). We also recommend the reader the excellent book *Sundials: History, theory, and practice* (see [466]).

Below we will show how trigonometry can be used to calculate the positions of the hour lines for vertical and horizontal sundials. The words "vertical" and "horizontal" are used in their normal sense, that is, in the direction of gravity and at right angles to this.

12.1.11.1 Equatorial sundials

Let us imagine the Earth as a giant sundial (wee figure below). The Earth's axis is tilted actually (earyl 121st century according to holocene calendar) at an angle of 23.5° to the plane of its orbit around the Sun. As the Earth rotates on its axis, the shadow of a vertical stick at the pole would form a circle on the surface of the Earth parallel to the equator. If the circle is divided into 24 equal hour marks, the position of the shadow around the circle would give the time. Sundials based on this principle are named "equatorial sundials".

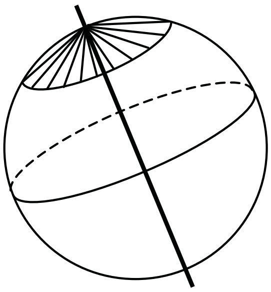


Figure 12.95: Representing the Earth as a giant sundial

In any sundial, the part that casts the shadow is named the "gnomon" as we saw it. Here is a very nice visual reproduced with the authorization of the British Sundial Society:

(source: `https://sundialsoc.org.uk`, author: Tony Moss)

For an equatorial sundial, the gnomon must be parallel to the Earth's axis. In the figure below P is in the southern hemisphere at latitude L. The diagram shows why the angle that the gnomon makes with the horizontal is equal to the latitude. The dial with the hour marks must be perpendicular to the gnomon. In the southern hemisphere the gnomon will point to the south celestial pole (in the northern hemisphere, it points towards the pole star):

to polaris
equator
S

Figure 12.97: **Equatorial sundials at different latitudes**

The hour lines are equally spaced, with 15° intervals (angular speed of Earth). At midsummer the Sun is directly in line with the gnomon so there is no shadow. Between the spring equinox (22 September) and the autumn equinox (22 March), the shadow falls on the upper face of the dial. Between 22 March and 22 September, when the Sun is lower in the sky, the shadow falls on the under side. Obviously not all hours are indicated because we can't see any shadow during during the night... (however in reality they are all indicated for aesthetic reasons even if its dumb...).

12.1.11.2 Vertical sundials

For a vertical sundial, the circular equatorial dial presented earlier above is projected onto a vertical plane and this results obviously to an ellipse (see figure below). The semi-major axis (parallel to the ground), a, is the radius of the equatorial dial. If b is the semi-minor axis of the ellipse (the reader can also refer to the side view of the previous figure to understand):

$$\sin\left(\frac{\pi}{2}-L\right)=\cos(L)=\frac{a}{b} \tag{12.1.669}$$

Hence:

$$b=\frac{a}{\cos(L)} \tag{12.1.670}$$

Figure 12.99: Projection of the equatorial dial to form the ellipse of the vertical dial

The gnomon of the vertical sundial makes an angle of $90^\circ - L$ with the vertical (that is, an angle L with the horizontal), as shown below:

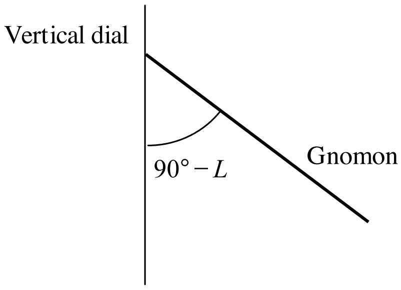

Figure 12.100: **Side view of gnomon of vertical sundial**

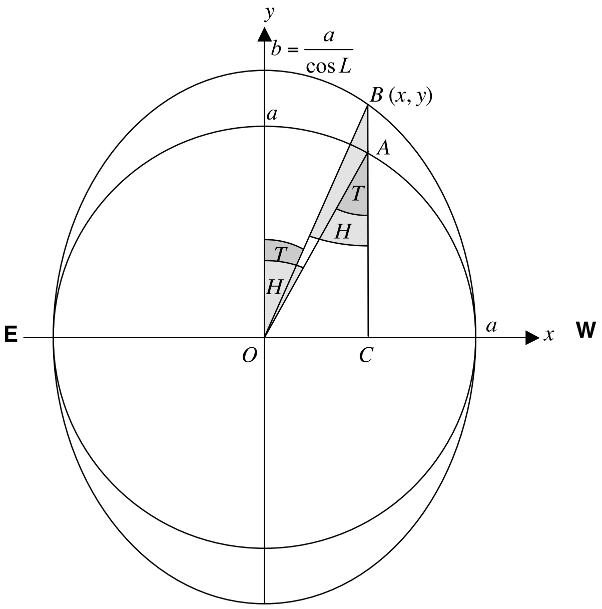
Let us calculate now the angle hours for the vertical sundial assuming we want to depict the graduation on a circle for esthetical reasons.

In the southern hemisphere, the vertical dial is north-facing. Unlike the equatorial dial, the hour angles are not equally spaced. In the figure below the angle T is the hour angle measured from the north-south line around the equatorial dial:



Angle H is the projected hour angle on the ellipse of the vertical dial. Using the equation for an ellipse (see section Analytical Geometric page 2768) and applying trigonometry in triangles ΔOAC and ΔOBC, we can find H in terms of L and T.

Let us remind for this purpose the equation of the ellipse:

$$\frac{x^2}{a^2}+\frac{y^2}{b^2}=1 \qquad (12.1.671)$$

Substituting in it $b = a/\cos(L)$, we get:

$$\frac{x^2}{a^2}+\frac{y^2\cos^2(L)}{a^2}=1 \qquad (12.1.672)$$

After simplification:

$$x^2+y^2\cos(L)=a^2 \tag{12.1.673}$$

but from the triangle ΔAOC, we have:

$$x=a\sin(T) \tag{12.1.674}$$

Therefore substituting and rearranging we get:

$$y^2=\frac{\left(a^2-a^2\sin^2(T)\right)}{\cos^2(L)}=\frac{a^2\left(1-\sin^2(T)\right)}{\cos^2(L)}=\frac{a^2\cos^2(T)}{\cos^2(L)} \tag{12.1.675}$$

Hence:

$$y=\frac{a\cos(T)}{\cos(L)} \tag{12.1.676}$$

From the triangle ΔOBC:

$$\tan(H)=\frac{x}{y} \tag{12.1.677}$$

Using the two relation we got above:

$$x=a\sin(T) \qquad y=\frac{a\cos(T)}{\cos(L)} \tag{12.1.678}$$

We can write:

$$\tan(H)=\frac{x}{y}=\frac{a\sin(T)}{\dfrac{a\cos(T)}{\cos(L)}}=\frac{a\sin(T)\cos(L)}{a\cos(T)}=\tan(T)\cos(L) \tag{12.1.679}$$

So finally:

$$H=\tan^{-1}(\tan(T)\cos(L)) \tag{12.1.680}$$

The hour angles, H, for 6 am to 12 noon for a vertical dial in Melbourne (latitude $37.7°$) are shown in the table below:

Time	T (°)	H (°)
12 noon	0	0.0
11 am	15	12.0
10 am	30	24.6
9 am	45	38.4
8 am	60	53.9
7 am	75	71.3
6 am	90	90.0

The angles are symmetrical about the noon line for 1 pm to 6 pm:

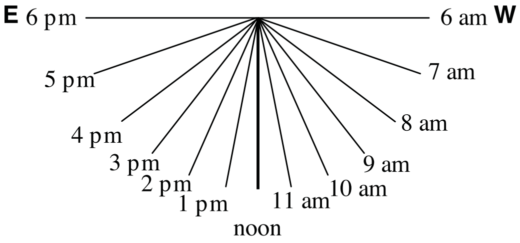


Figure 12.101: **Hour angles for vertical sundial in Melbourne**

12.1.11.3 Horizontal sundials

For a horizontal sundial, the circular equatorial dial is projected onto a horizontal plane as an ellipse as depicted in the figure below:

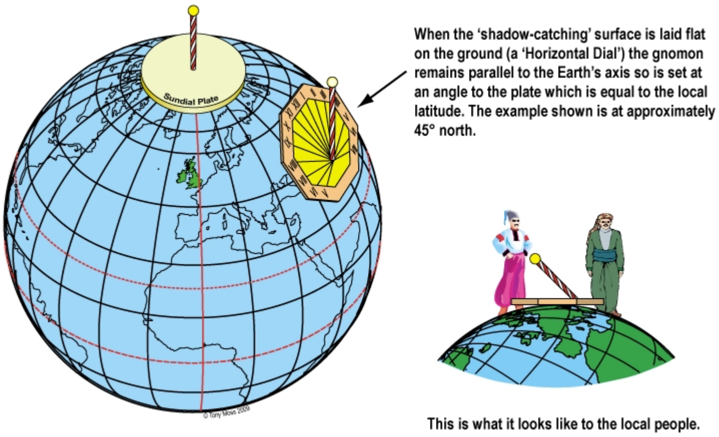
Figure 12.102: Hour angles for vertical sundial

Here is a very nice visual reproduced with the authorization of the British Sundial Society:



Sundial Plate
© Tony Moss 2009

When the 'shadow-catching' surface is laid flat on the ground (a 'Horizontal Dial') the gnomon remains parallel to the Earth's axis so is set at an angle to the plate which is equal to the local latitude. The example shown is at approximately 45° north.

This is what it looks like to the local people.

Figure 12.103: Horizontal sundial illustrated on the globe
(source: `https://sundialsoc.org.uk`, author: Tony Moss)

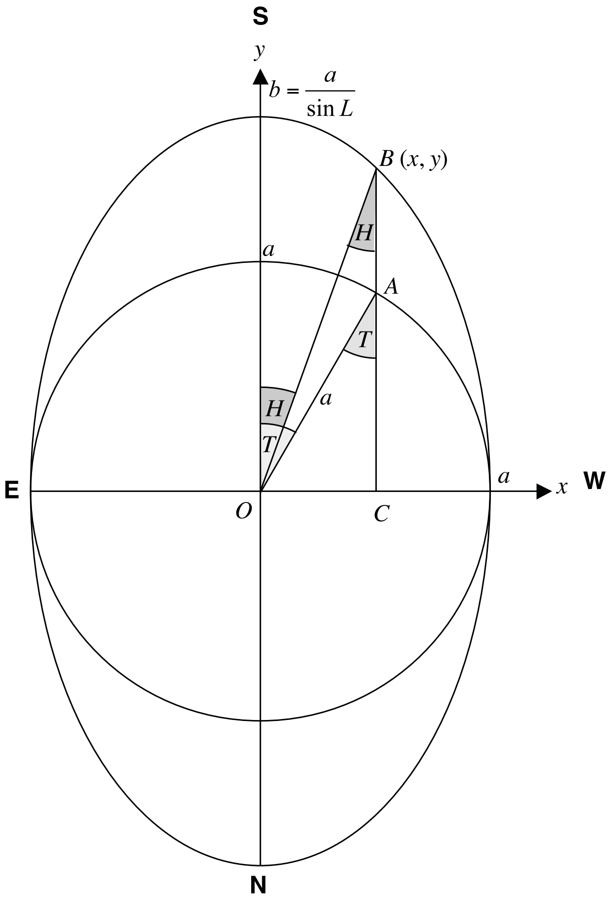
As for the equatorial and vertical sundials, the gnomon makes an angle L with the horizontal. The semi-minor (east-west) axis is a, the radius of the equatorial dial. If b is the semi-major (north-south) axis of the ellipse and we get therefore:

$$\sin(L)=\frac{a}{b} \tag{12.1.681}$$

Hence:

$$b=\frac{a}{\sin(L)} \tag{12.1.682}$$

In the figure below, T is the hour angle measured from the north-south line around the equatorial dial:



The angle H is the projected hour angle on the ellipse of the horizontal dial. Using exactly the same approach as for the vertical sundial, the parametric equations for the ellipse for the horizontal sundial are:

$$x = a\sin(T) \qquad y = \frac{a\cos(T)}{\sin(L)} \tag{12.1.683}$$

From:

$$\tan(H) = \tan(T)\sin(L) \tag{12.1.684}$$

We get that the hour angles are given by:

$$H = \tan^{-1}(\tan(T)\sin(L)) \tag{12.1.685}$$

The hour angles, H, for a horizontal sundial in Melbourne are shown in the table below:

Time	T (°)	H (°)
6 am	90	90.0
7 am	75	66.3
8 am	60	46.6
9 am	45	31.4
10 am	30	19.4
11 am	15	9.3
12 noon	0	0.0

The latitude 37.7° has been used. For 11 am , for example, $H = \tan^{-1}(\tan(15^\circ)\sin(37.7^\circ)) \cong 9.3^\circ$. Unlike the vertical sundial, the numbers are anticlockwise for a horizontal sundial in the southern hemisphere.

The angles are symmetrical about the noon line too:

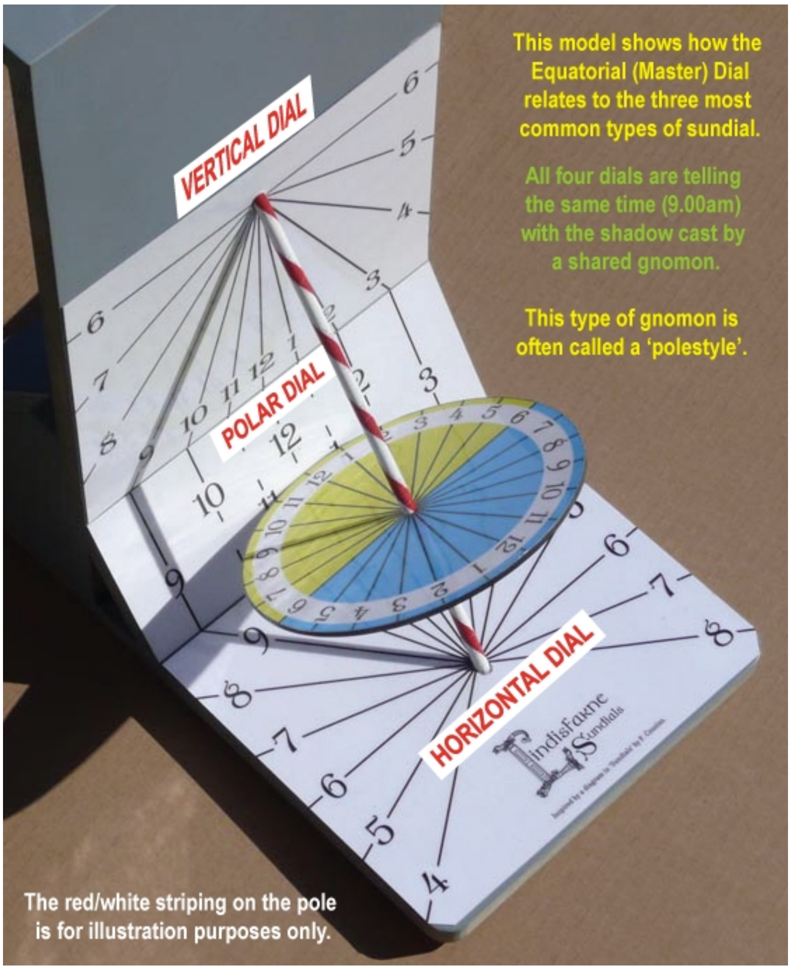
Figure 12.104: Hour angles for horizontal sundial in Melbourne

We can see below an interesting combo of a vertical, polar and horizontal dial:



This model shows how the Equatorial (Master) Dial relates to the three most common types of sundial.
All four dials are telling the same time (9.00am) with the shadow cast by a shared gnomon.
This type of gnomon is often called a 'polestyle'.
VERTICAL DIAL
POLAR DIAL
HORIZONTAL DIAL
LindisFarne Sundials
The red/white striping on the pole is for illustration purposes only.

Figure 12.105: Three types of sundials in one piece (manufacturer: LindisFnake Sundials)

12.1.11.4 Anammelatic (azimuthal) sundials

The anammelatic (azimuthal) has instead of a gnomon set at the angle of the latitude, a vertical gnomon (relatively to the ground) or person that stands on the north-south line at a calculated position according to their height (see the mosaic of photo with the various sundial earlier above!).

If we consider a right-angled triangle formed by the vertical gnomon (or person) and the distance d from the center of the sundial at which the person stands, the hypotenuse of this triangle has to do an angle of $37.8028°$ (the local latitude of Melbourne for example) with the horizontal:

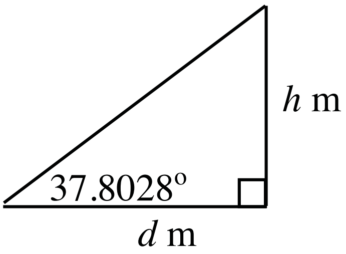


Figure 12.106: Relationship between height and position for anammelatic sundial

For example, for a person of height 1.80 [m]:

$$\tan(37.8028°)=\frac{1.80}{d} \tag{12.1.686}$$

Hence:

$$d=\frac{1.80}{\tan(37.8028°)}\cong 2.32\,[\text{m}] \tag{12.1.687}$$

So a person of height 1.8 [m] would stand on the north-south line at a position 2.32 [m] from the center of the sundial.

If the vertical (human) gnomon were to be replaced with a right-angled triangle with its hypotenuse making an angle L with the horizontal, then the shadow of the hypotenuse at any given hour would fall along the hour line. The tip of the person's shadow would meet the hour line as shown below:

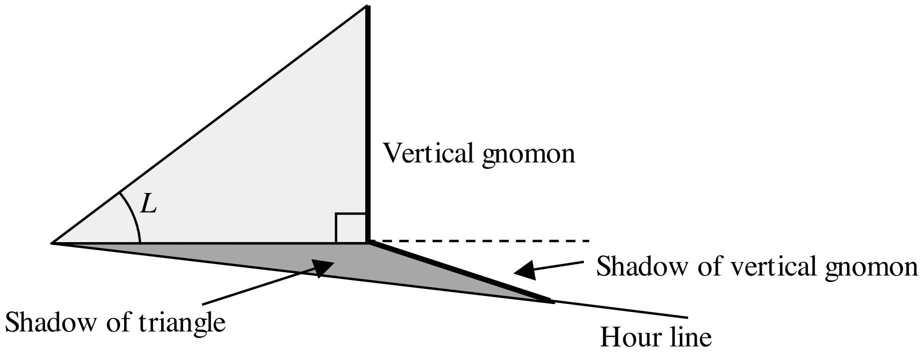

Figure 12.107: Tip of shadow of human gnomon meets the hour line

The figure below shows the view from above of the hour line, $\overline{OP}$, and the shadow, $\overline{GP}$, of a person standing on the solar clock at G. These two lines intersect at P:

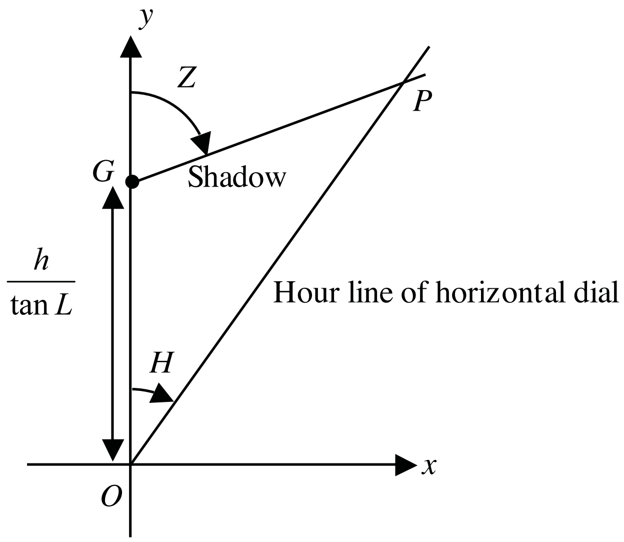

Figure 12.108: Intersection of person's shadow with the hour line.

The coordinates of P can be found by solving simultaneously the equations for $\overline{GP}$ and $\overline{OP}$.

The angle Z (the Sun's azimuth chosen relatively to the North cardinal in the developments that will follow is equal to $A=\pi-Z$ as the Sun is at the opposite direction to the shadow) that the shadow of a vertical gnomon makes with the north-south line depends on the latitude, the time of day and the declination (angular distance of a celestial body North $(+)$ or South $(-)$ from the celestial equator) of the Sun, which changes through the day and through the year.

For pedagogical reasons let us first consider the simple case of the equinox when the declination angle is $D=0^\circ$.

We know that the Sun appears to move approximately actually around the star Polaris in an approximate large circle. At the equinox when $D=0^\circ$ this circle is exactly the celestial equator. We can describe the position of the Sun by its angle relative to some fixed reference point. For convenience we take this point to be noon, at which time the Sun is highest. The angle T of the Sun relative to the noon point is named the "hour angle", with $T=0^\circ$ at noon. In fact $T=15^\circ\cdot t$, where t is the time (in hours) past noon (remember the the Sun rise at the East and set at the West):

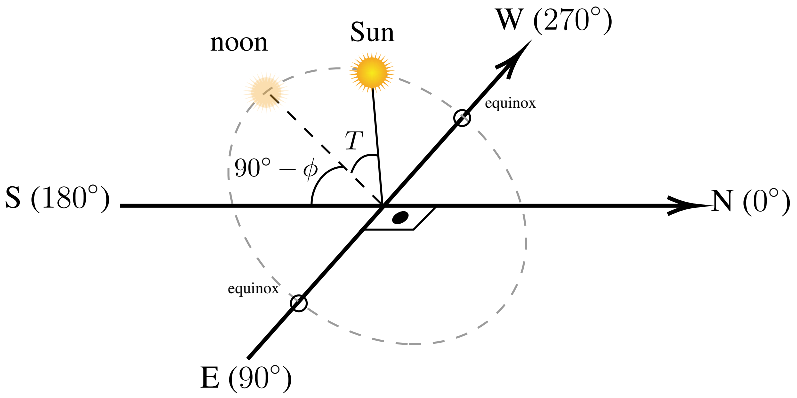

Figure 12.109: **Finding the hour angle**

Now, what shape do we get if we look at the shadow cast by a vertical pointer onto a horizontal surface? To answer this we have to project the circle that the Sun makes. If $D=0^\circ$ this circle is at an angle of $90^\circ-\phi$ to the horizontal and intersects the horizontal at 6 am and 6 pm on the equinoxes (as at this special day of the year there is 12 hours of day and 12 hours of night).

If R is the radius of the circle on which the Sun moves and if the x-axis is aligned East-West and the y-axis aligned North-South, then the (x,y) coordinates of the Sun can only be given by (the reader can check the validity of these relations for some remarkable angles):

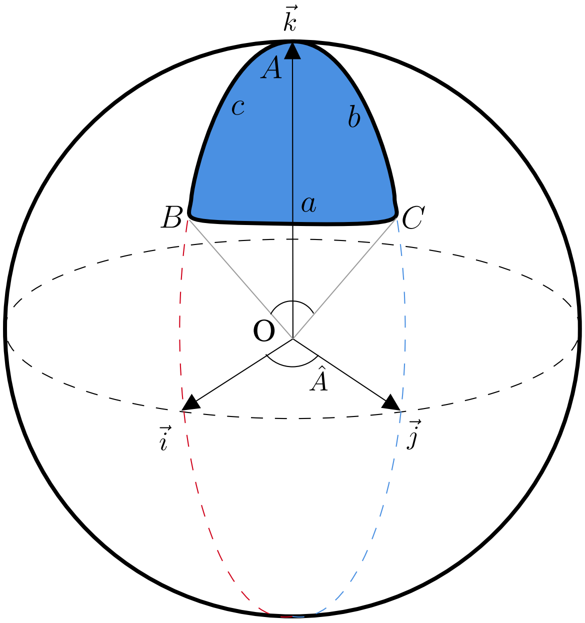
$$x=R\sin(T)\qquad y=R\cos(T)\sin(\phi) \tag{12.1.688}$$

The angle the shadow of the Sun makes with respect to the y-axis is named the "azimuth" and we write this as Z. It is given therefore by:

$$\cot(Z)=\frac{y}{x}=\sin(\phi)\cot(T) \tag{12.1.689}$$

Now that we have done this the angle Z can be calculated according to the four-part formula where T is the angle hour measured clockwise from the north-south line, L is the latitude, and D is the declination (angular distance of a celestial body North $(+)$ or South $(-)$ from the celestial equator) of the Sun.

Now let us remind the four-part formula proved in the section of Trigonometry (see page 2548):



Let the sides a, b, c of $\triangle ABC$ be measured by the angles subtended at O, where a, b, c are opposite A, B, C respectively.

We proved that:

$$\cos(a)\cos(\hat{C}) = \sin(a)\cot(b) - \sin(\hat{C})\cot(\hat{B}) \tag{12.1.690}$$

Now let us represent the following configuration with also a spherical triangle whose vertices are defined by the zenith of the gnomon, the true geographical north and the Sun's projection on a celestial sphere of arbitrary radius:

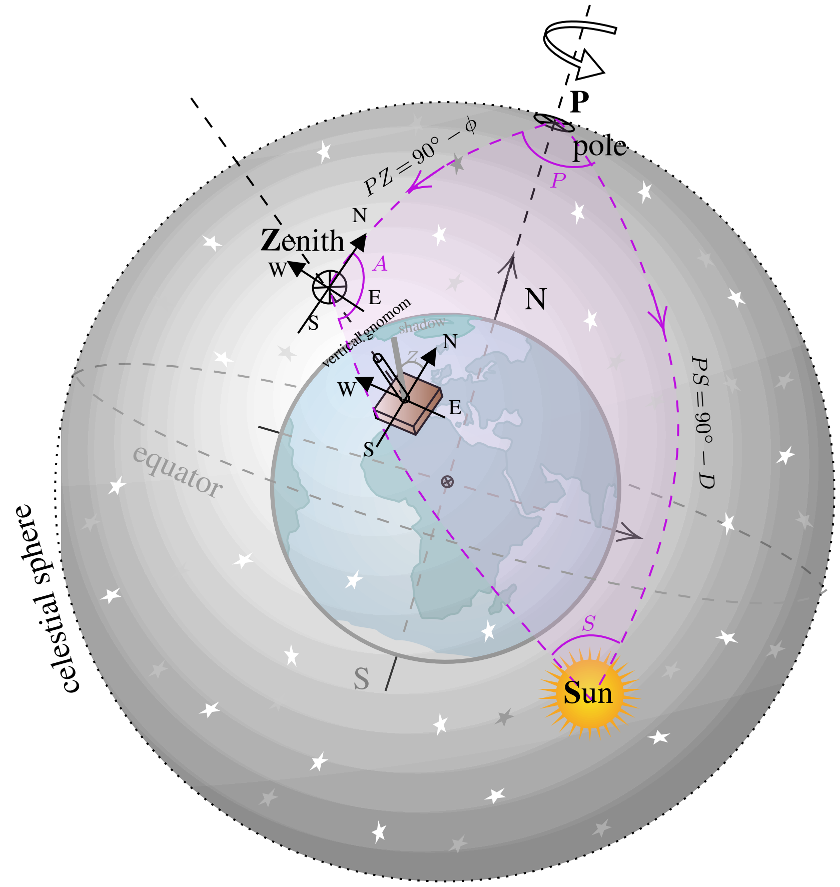


Figure 12.110: **Anammelatic sundial on Earth with a spherical defined triangle**

Therefore the four-parts formula for the spherical triangle defined by the gnomon zenith (Z), the geographical pole (P) and the Sun position (S) is given by:

$$\cos(PZ)\cos(P)=\sin(PZ)\cot(PS)-\sin(P)\cot(A) \tag{12.1.691}$$

Or explicitly:

$$\cos(90^\circ-\phi)\cos(P)=\sin(90^\circ-\phi)\cot(90^\circ-D)-\sin(P)\cot(A) \tag{12.1.692}$$

Using trigonometric complementary angles relations, this reduces to:

$$\sin(\phi)\cos(P)=\cos(\phi)\tan(D)-\sin(P)\cot(A) \tag{12.1.693}$$

Now remember that the azimuth angle A (Sun's angle position relatively to the North) is related to Z (the angle of the gnomon shadow relatively to the north) by:

$$A=\pi-Z \tag{12.1.694}$$

Therefore the four-parts formula becomes:

$$\sin(\phi)\cos(P)=\cos(\phi)\tan(D)-\sin(P)\cot(\pi-Z) \tag{12.1.695}$$

Hence using again trigonometric complementary angles relations:

$$\sin(\phi)\cos(P)=\cos(\phi)\tan(D)+\sin(P)\cot(Z) \tag{12.1.696}$$

Rearranging we get:

$$\cot(Z)=\frac{\sin(\phi)\cos(P)-\cos(\phi)\tan(D)}{\sin(P)}=\sin(\phi)\cot(P)-\frac{\cos(\phi)\tan(D)}{\sin(P)} \tag{12.1.697}$$

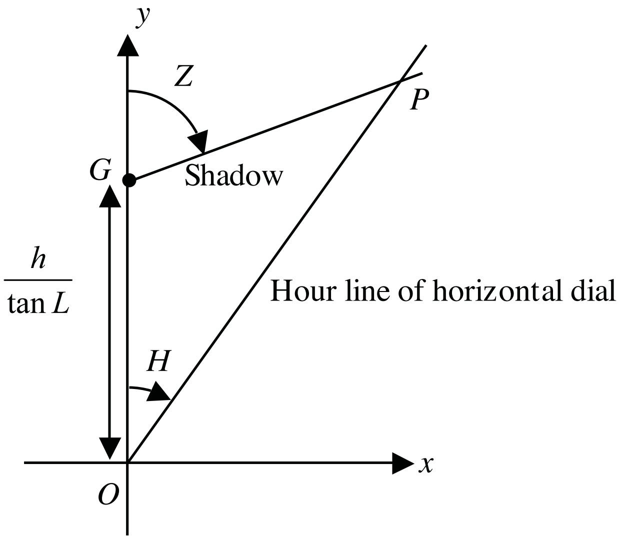
And let us come back to our initial notation by denoting the latitude L instead of ϕ and T (hour angle) instead of P:

$$\cot(Z)=\frac{\sin(L)\cos(T)-\cos(L)\tan(D)}{\sin(T)}=\sin(L)\cot(T)-\frac{\cos(L)\tan(D)}{\sin(P)} \tag{12.1.698}$$

Notice that when $D=0°$ (equinox) we fall back on:

$$\cot(Z)=\sin(\phi)\cot(T)=\sin(L)\cot(T) \tag{12.1.699}$$

Now we can use this spherical trigonometric relation to study (we reproduce again this figure here for convenience):



We have for the hour line $\overline{OP}$:

$$y=x\tan(90°-H)=\frac{x}{\tan(H)} \tag{12.1.700}$$

But remember that we have seen during our study of the equatorial sundial (see page 5447) that:

$$\tan(H)=\tan(T)\sin(L) \tag{12.1.701}$$

Therefore:

$$y=\frac{x}{\tan(T)\sin(L)} \tag{12.1.702}$$

And for the the shadow $\overline{GP}$ we have:

$$y=\frac{h}{\tan(L)}+x\cot(Z) \tag{12.1.703}$$

Substituting for $\cot(Z)$ we just got thanks to the four-parts formula of spherical trigonometry, we get:

$$y=\frac{h}{\tan(L)}+\frac{x(\sin(L)\cos(T)-\tan(D)\cos(L))}{\sin(T)} \tag{12.1.704}$$

From:

$$y=\frac{x}{\tan(T)\sin(L)} \quad \text{and} \quad y=\frac{h}{\tan(L)}+\frac{x(\sin(L)\cos(T)-\tan(D)\cos(L))}{\sin(T)} \tag{12.1.705}$$

equating we get:

$$\frac{x}{\tan(T)\sin(L)}=\frac{h}{\tan(L)}+\frac{x(\sin(L)\cos(T)-\tan(D)\cos(L))}{\sin(T)} \tag{12.1.706}$$

Expliciting $\tan(T)$:

$$\frac{x\cos(T)}{\sin(T)\sin(L)}=\frac{h\cos(L)}{\sin(L)}+\frac{x(\sin(L)\cos(T)-\tan(D)\cos(L))}{\sin(T)} \tag{12.1.707}$$

Multiplying both sides by $\sin(T)\sin(L)$:

$$\begin{aligned}x\cos(T)&=h\sin(T)\cos(L)+x\sin(L)(\sin(L)\cos(T)-\tan(D)\cos(L))\\&=h\sin(T)\cos(L)+x\left(\sin^2(L)\cos(T)-\sin(L)\tan(D)\cos(L)\right)\end{aligned} \tag{12.1.708}$$

Hence after rearranging:

$$\begin{aligned}h\sin(T)\cos(L)&=x\left(\cos(T)-\sin^2(L)\cos(T)+\sin(L)\tan(D)\cos(L)\right)\\&=x\left(\cos(T)\left(1-\sin^2(L)\right)+\sin(L)\tan(D)\cos(L)\right)\\&=x\left(\cos(T)\cos^2(L)+\sin(L)\tan(D)\cos(L)\right)\\&=x\cos(L)(\cos(T)\cos(L)+\tan(D)\sin(L))\end{aligned} \tag{12.1.709}$$

Therefore:

$$h\sin(T)=x(\cos(T)\cos(L)+\tan(D)\sin(L)) \tag{12.1.710}$$

So for the x component we have:

$$x=\frac{h\sin(T)}{\cos(T)\cos(L)+\tan(D)\sin(L)} \tag{12.1.711}$$

Substituting to find the y-coordinate of the intersection:

$$\begin{aligned}y&=\frac{x}{\tan(T)\sin(L)}=\frac{h\sin(T)}{\tan(T)\sin(L)(\cos(T)\cos(L)+\tan(D)\sin(L))}\\&=\frac{h\cos(T)}{\sin(L)(\cos(T)\cos(L)+\tan(D)\sin(L))}\end{aligned} \tag{12.1.712}$$

Hence the coordinates of the tip of the vertical gnomon (or person's shadow) of the analemmatic sundial:

$$\boxed{\left(\frac{h\sin(T)}{\cos(T)\cos(L)+\tan(D)\sin(L)},\frac{h\cos(T)}{\sin(L)(\cos(T)\cos(L)+\tan(D)\sin(L))}\right)} \tag{12.1.713}$$

where for reminder T is the angle hour measured clockwise from the north-south line, L is the latitude, and D is the declination (angular distance of a celestial body North (+) or South (−) from the celestial equator) of the Sun.

Notice that at the famous moment of equinoxes (when $D=0°$), we get a horizontal line since the y component is equal to:

$$y=\frac{h\cos(T)}{\sin(L)(\cos(T)\cos(L)+\tan(D)\sin(L))}=\frac{h\cos(T)}{\sin(L)\cos(T)\cos(L)}=\frac{h}{\sin(L)\cos(L)}=c^{te} \tag{12.1.714}$$

Notice that for the proof of this parametric equation we never assumed multiple rays of lights but only one ray of light (hence rays of light are not assumed parallel nor divergent).

For an analemmatic sundial positioned at latitude $L=37.8°$, the figure below shows a plot of the hour lines and the positions of the shadow tip during the day for the equinoxes and the summer and winter solstices ($D=0°, 23.5°$ and $-23.5°$ respectively) for a person of height 1.80 [m] standing at $G(0,2.32)$:

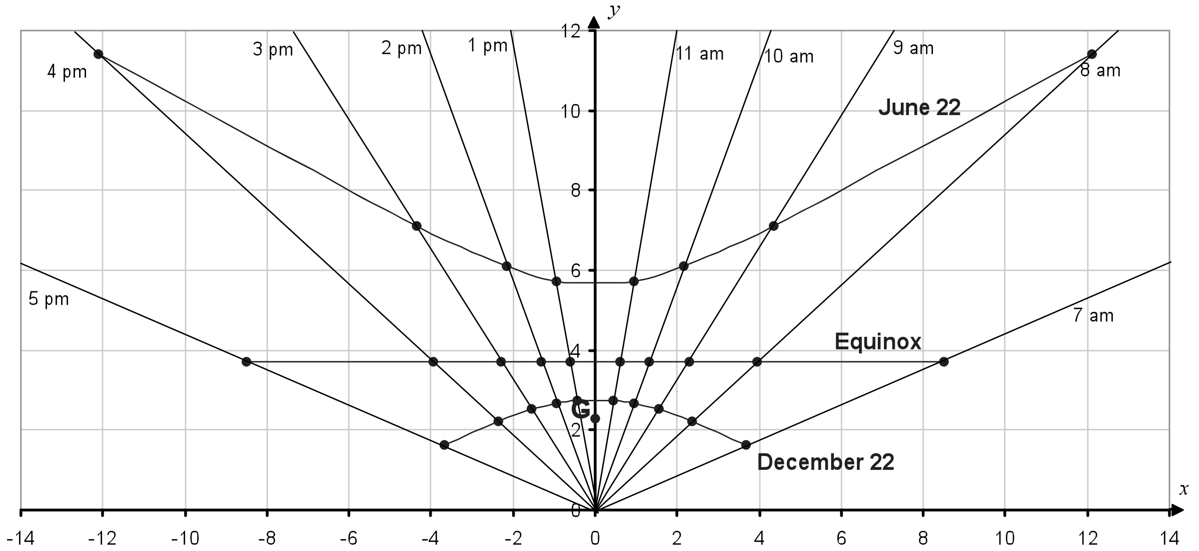


Figure 12.111: Hour lines and the positions of the shadow tip during the day for the equinoxes and the summer and winter solstices

Above we can see the horizontal line of the both equinox (that are obviously superposed) and the both hyperbolas of solstices.

Here is a Python™ code to get the above graph:

```python

    else:
        # Extend the hour lines to intersect with the June 22nd curve
        x_max = all_coords["June 22"][0][i]
        y_max = all_coords["June 22"][1][i]

    # Plot the line from the stick (G) to the shadow tip
    plt.plot([Gx, x_max], [Gy, y_max], color='black', lw=0.5)

    # Add a point at each intersection for each declination curve
    for label in D_labels:
        if i < len(all_coords[label][0]):  # Safety check for June 22
            x_i = all_coords[label][0][i]
            y_i = all_coords[label][1][i]
            plt.plot(x_i, y_i, 'ko', markersize=3)  # Plot the intersection point

    # Label the hours along the Equinox curve
    dx = all_coords["Equinox"][0][i] - Gx  # Difference in x between G and the shadow tip
    dy = all_coords["Equinox"][1][i] - Gy  # Difference in y between G and the shadow tip
    norm = np.sqrt(dx**2 + dy**2)  # Normalize the vector
    hour = hours[i]
    label_hr = f"{hour} am" if hour < 12 else ("12 pm" if hour == 12 else f"{hour - 12} pm")  # Hour label
    label_x = all_coords["Equinox"][0][i] + 0.4 * dx / norm  # Position label along the curve
    label_y = all_coords["Equinox"][1][i] + 0.4 * dy / norm  # Position label along the curve
    plt.text(label_x, label_y, label_hr, fontsize=8, ha='center')  # Plot the hour label

# Plot the position of the stick (G)
plt.plot(Gx, Gy, 'ko')  # Mark the position of G with a black dot
plt.text(Gx + 0.2, Gy, 'G', fontsize=9)  # Label the position of G

# Final plot settings
plt.xlabel('x')
plt.ylabel('y')
plt.title('Shadow tip positions (L = 37.8)')
plt.legend()  # Show the legend
plt.grid(True)  # Enable grid
ax.set_aspect('equal')  # Set equal scaling on both axes
plt.xlim(-13, 13)  # Set x-axis limits
plt.ylim(-1, 12)  # Set y-axis limits
plt.tight_layout()  # Adjust layout to avoid clipping
plt.show()  # Show the plot
```

That gives:

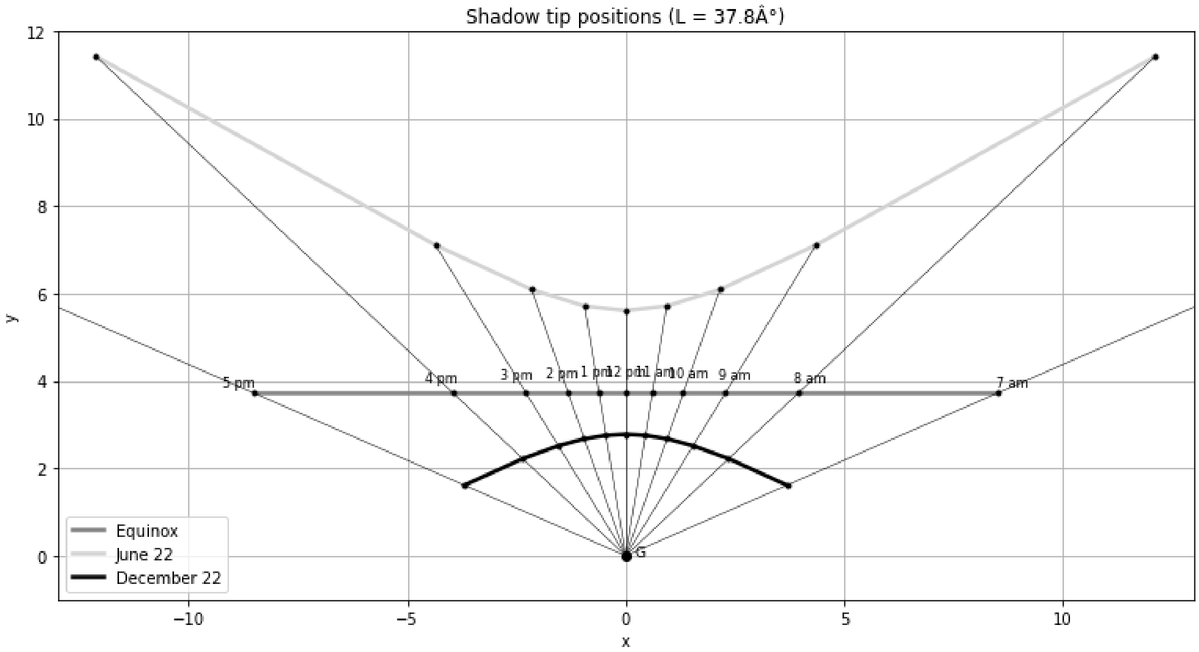

Figure 12.112: Hour lines and the positions of the shadow tip during the day for the equinoxes and the summer and winter solstices in Python™

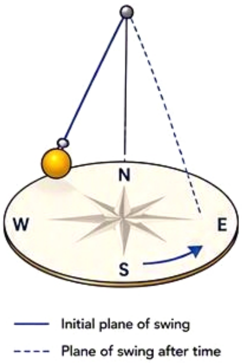
Obviously our results match with reality because the Earth isn't flat, rotates on itself and "turns" around the Sun...

1 THE FOUCAULT PENDULUM

A long pendulum swings in a fixed plane in inertial space. As Earth rotates beneath it, the plane of swing appears to rotate.

- Clockwise in the Northern Hemisphere
- Counterclockwise in the Southern Hemisphere



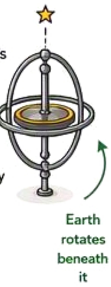
N
W
E
S
Initial plane of swing
Plane of swing after time

✓ Matches the prediction for a rotating Earth.

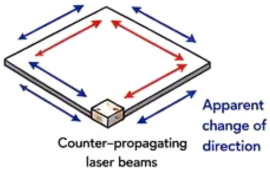
2 THE GYROSCOPE (ESPECIALLY GYRO LASERS)

A gyroscope maintains its orientation in inertial space. As Earth rotates, the gyroscope's axis appears to change direction relative to the ground.

- Mechanical gyros show a drift consistent with Earth's rotation.
- Ring laser gyros use two counter-propagating laser beams. A rotation of the system produces a frequency difference (Sagnac effect).



Earth rotates beneath it



Apparent change of direction
Counter-propagating laser beams

$$\Delta f = \frac{4A\Omega}{\lambda P}$$

where:
A = area enclosed by ring
P = perimeter of ring
Ω = Earth's rotation rate
λ = laser wavelength

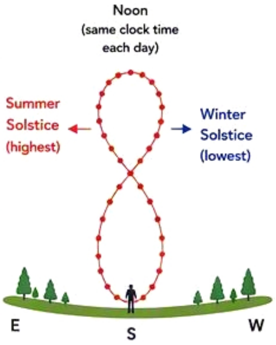
✓ Gyro lasers measure Earth's rotation rate with extraordinary precision (used in navigation and geodesy).

3 THE ANALEMMA

An analemma is the figure traced by the Sun in the sky when photographed at the same clock time each day over a year.

The figure-eight shape arises only because:

1. Earth rotates on its axis (giving day and night)
2. Earth orbits the Sun in an elliptical orbit whose plane is tilted.



Noon
(same clock time each day)
Summer Solstice (highest)
Winter Solstice (lowest)
E
S
W

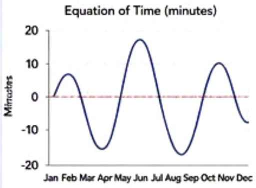
✓ Explained only if Earth rotates on its axis while orbiting the Sun.

4 THE EQUATION OF TIME (TIME EQUATION)

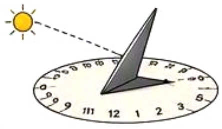
The equation of time is the difference between apparent solar time (from the Sun) and mean solar time (uniform 24-hour days).

It has two causes that occur only if:

1. Earth rotates on its axis (defining day length)
2. Earth revolves around the Sun in an elliptical orbit with a tilted axis.



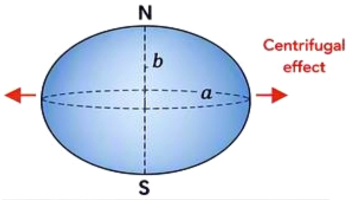
How it enables sundials:



✓ Works only if Earth rotates on its axis while orbiting the Sun.

5 EARTH'S EQUATORIAL BULGE

Earth is not a perfect sphere. It is an oblate spheroid—wider at the equator—because Earth's rotation produces centrifugal force that pushes matter outward.



N
b
a
S
Centrifugal effect

Typical values:

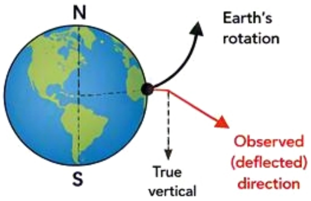
Equatorial radius	$a \approx 6378.1$ km
Polar radius	$b \approx 6356.8$ km
Flattening	$f = \frac{a-b}{a} \approx \frac{1}{298.257}$

✓ Such a bulge exists only if Earth rotates on its axis.

6 THE EÖTVÖS EFFECT

A moving mass (like Earth) "drags" local spacetime, changing the apparent direction of gravity.

On Earth's surface, this produces a tiny but measurable deflection toward the direction of Earth's rotation.



N
S
Earth's rotation
True vertical
Observed (deflected) direction

✓ The deflection reverses in the Southern Hemisphere. It occurs only because Earth rotates.

7 THE CORIOLIS EFFECT

In a rotating frame (like Earth), moving objects are deflected from a straight path.

Northern Hemisphere

Southern Hemisphere

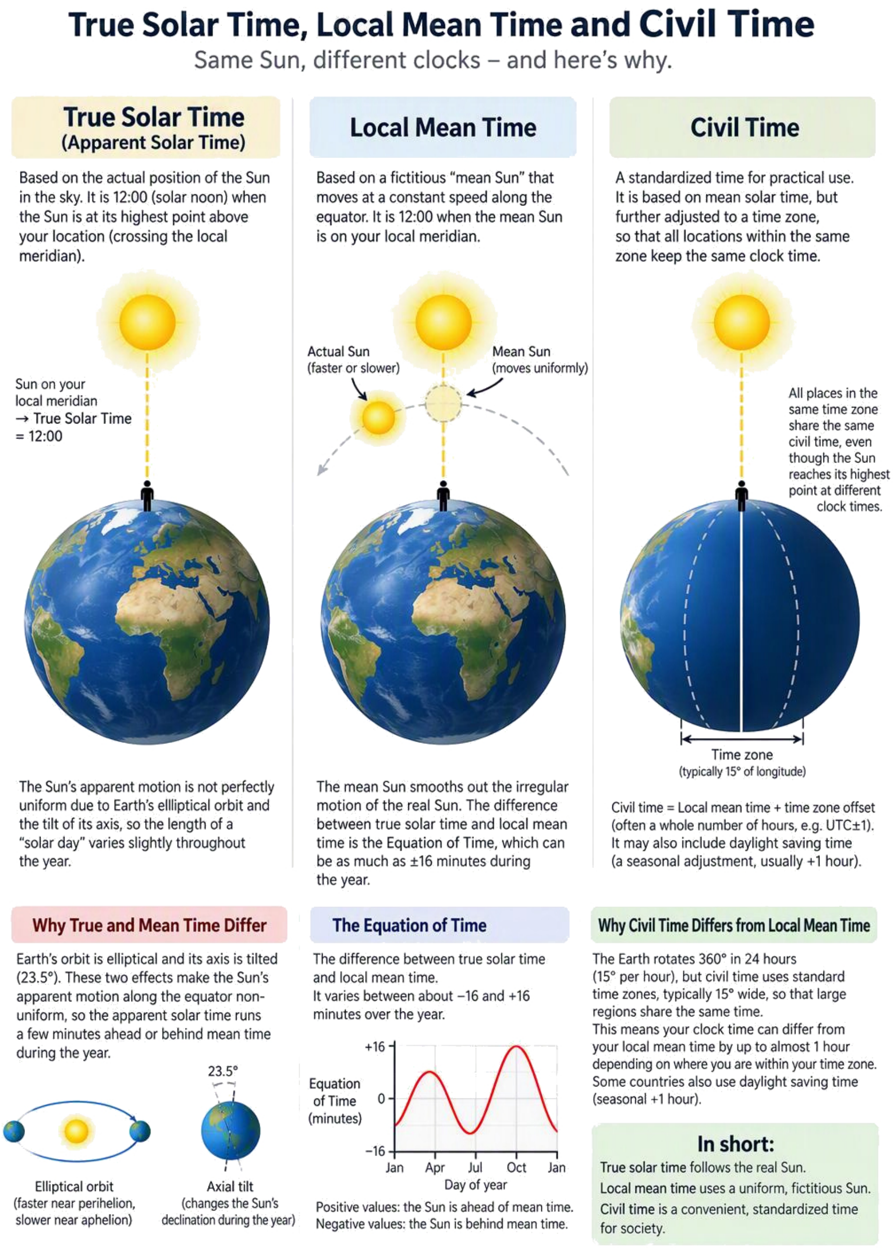
✓ Arises only in a rotating Earth. Its direction reverses between hemispheres.

12.1.12 Apparent solar time (true solar time)

Now that we know what is the equation of time and what are sundials and how to read their shadow we can finally deal with the concepts of true solar time, civil time and local mean time.

Definition (#12.1.530): "Apparent solar time" (AST), also named "true solar time" (TST), is based directly on the observable position of the Sun (actually a G2V-type star, aka yellow dwarf) at a specific location, where solar noon occurs at the exact moment the Sun reaches its highest point in the local sky, causing true solar days to fluctuate slightly in length throughout the year due to Earth's elliptical orbit and axial tilt.

Definition (#12.1.531): "Civil time" (CT), by contrast, is a standardized artificial timekeeping system created for practical daily life that divides the globe into fixed time zones and uses an idealized, mathematically averaged "mean Sun" so that every clock day consists of exactly 24 uniform hours.



True Solar Time, Local Mean Time and Civil Time

Same Sun, different clocks – and here's why.

True Solar Time (Apparent Solar Time)

Based on the actual position of the Sun in the sky. It is 12:00 (solar noon) when the Sun is at its highest point above your location (crossing the local meridian).

The Sun's apparent motion is not perfectly uniform due to Earth's ellliptical orbit and the tilt of its axis, so the length of a "solar day" varies slightly throughout the year.

Local Mean Time

Based on a fictitious "mean Sun" that moves at a constant speed along the equator. It is 12:00 when the mean Sun is on your local meridian.

The mean Sun smooths out the irregular motion of the real Sun. The difference between true solar time and local mean time is the Equation of Time, which can be as much as ±16 minutes during the year.

Civil Time

A standardized time for practical use. It is based on mean solar time, but further adjusted to a time zone, so that all locations within the same zone keep the same clock time.

All places in the same time zone share the same civil time, even though the Sun reaches its highest point at different clock times.

Civil time = Local mean time + time zone offset (often a whole number of hours, e.g. UTC±1). It may also include daylight saving time (a seasonal adjustment, usually +1 hour).

Why True and Mean Time Differ

Earth's orbit is elliptical and its axis is tilted (23.5°). These two effects make the Sun's apparent motion along the equator non-uniform, so the apparent solar time runs a few minutes ahead or behind mean time during the year.

The Equation of Time

The difference between true solar time and local mean time. It varies between about −16 and +16 minutes over the year.

Positive values: the Sun is ahead of mean time.
Negative values: the Sun is behind mean time.

Why Civil Time Differs from Local Mean Time

The Earth rotates 360° in 24 hours (15° per hour), but civil time uses standard time zones, typically 15° wide, so that large regions share the same time. This means your clock time can differ from your local mean time by up to almost 1 hour depending on where you are within your time zone. Some countries also use daylight saving time (seasonal +1 hour).

In short:

True solar time follows the real Sun.
Local mean time uses a uniform, fictitious Sun.
Civil time is a convenient, standardized time for society.

In other words, the apparent solar time (true solar time) is based on the apparent motion of the actual Sun. It is based on the apparent solar day, the interval between two successive returns of the Sun to the local meridian (see definition below)! Apparent solar time (true solar time) can also be crudely measured by a simple sundial. That's why time provided by sundials differ much of the time from time given by watches and clocks because the latter don't give the true solar time but instead an artificial convenient political and business time!

Definition (#12.1.532): The "local meridian" is an imaginary semicircle in the sky that stretches from due North to due South, passing directly overhead through the observer's zenith - the point straight above you. It is part of the celestial coordinate system and acts like a reference line for tracking celestial objects.

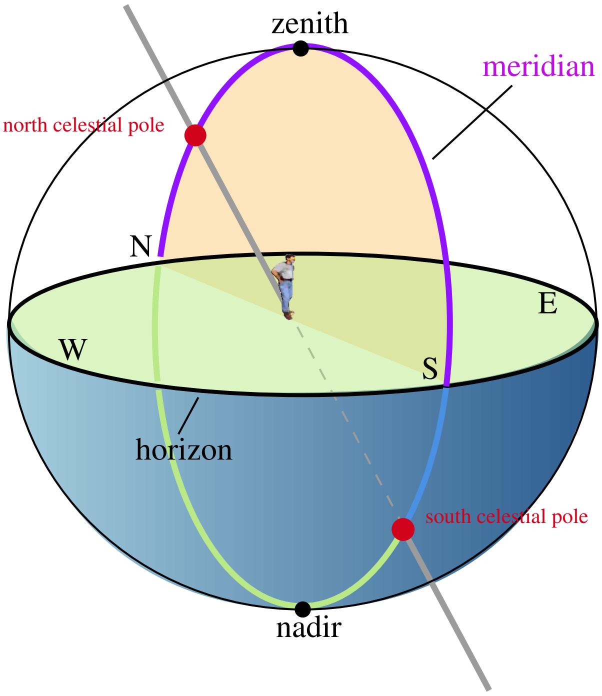


Figure 12.113: **Illustration of the concept of local meridian**

The length of a solar day varies through the year, and the accumulated effect produces seasonal deviations of up to 16 minutes from the mean as we have prove it earlier above during our derivation of the Equation of Time (see the maxima and minima of the plot of this equation). The effect has two main causes as we know: First, due to the eccentricity of Earth's orbit, Earth moves faster when it is nearest the Sun (perihelion) and slower when it is farthest from the Sun (aphelion) (see Kepler's laws of planetary motion at page 5233). Second, due to Earth's axial tilt (obliquity of the ecliptic), the Sun's annual motion is along a great circle (the ecliptic) that is tilted to Earth's celestial equator.

Our purpose here will be to learn how to compute the true solar time base on the (political) civil time with a detailed practical case.

Converting civil time to true time requires adjusting:

1. The eventual daylight saving time (DST)
2. The political time zone (TZ) if it doesn't correspond to the meridian

3. The very local longitude's offset from the time zone meridian (VLT)
4. Equation of Time (EoT) correction for the Earth's orbital eccentricity and axial tilt

So let's apply this to a companion example :

We want to know the true solar time of the civil time 2:00 PM (14:00) Gulf Standard Time (GST) on January 15 in Abu Dhabi (United Arab Emirates).

First, as far as we know, Abu Dhabi doesn't apply the daylight saving time (DST). Therefore we have:

$$\Delta\text{DST}_{\text{Abu Dhabi}} = 0 \tag{12.1.715}$$

Second, Abu Dhabi is really on a time zone that matches the political time zone. Hence:

$$\Delta\text{TZ}_{\text{Abu Dhabi}} = 0 \tag{12.1.716}$$

Third, Abu Dhabi is located West of the UTC+4 standard reference meridian, meaning the Sun (actually a G2V-type star, aka yellow dwarf) reaches its highest point there later than the time zone meridian dictates.

As for Abu Dhabi:

- Local Longitude $(\lambda_{\text{local long.}}): 54.37°\text{E}$
- GST Standard Meridian $(\lambda_{\text{GST std.}}): 60°\text{E}$

Because the Earth rotates at $15°$ per hour (or 4 minutes of time per degree of longitude), the very local time offset from the Gulf Standard Time meridian (GST) is:

$$\begin{aligned}\Delta\text{VLT}_{\text{long.}} &= (\lambda_{\text{local long.}} - \lambda_{\text{GST std.}}) \cdot 4\text{ min}/° \\ &= (54.37° - 60°) \cdot 4 = -22.52\text{ minutes } (-22\text{ min}31\text{ sec})\end{aligned} \tag{12.1.717}$$

Hence so far we have for local mean time (LMT):

$$\begin{aligned}\text{LMT} &= \text{CT} + \Delta\text{DST}_{\text{Abu Dhabi}} + \Delta\text{TZ}_{\text{Abu Dhabi}} + \Delta\text{VLT}_{\text{long.}} \\ &= \text{CT} + \Delta\text{DST}_{\text{Abu Dhabi}} + \Delta\text{TZ}_{\text{Abu Dhabi}} + (\lambda_{\text{local long.}} - \lambda_{\text{GST std.}}) \cdot 4\text{ min}/° \\ &= 14:00:00 + 0 + 0 - 00:22:31 = 13:37:29\end{aligned} \tag{12.1.718}$$

While LMT assumes a perfectly circular orbit, true solar time tracks the actual variable speed of the Sun across the sky. On January 15, the Earth is near perihelion, causing the actual Sun to be "slow" relative to the mean clock.

Let us remind us the expression of the Equation of Time (EoT) proven earlier above:

$$\text{Equation of Time} \cong -594.3\sin(2(\hat{M} + 12.25°)) - 459.3\sin(\hat{M})\ [\text{s}] \tag{12.1.719}$$

Hence in minutes:

$$\text{Equation of Time} \cong -9.905\sin(2(\hat{M} + 12.25°)) - 7.655\sin(\hat{M})\ [\text{min}] \tag{12.1.720}$$

with for the 15th january ($d=15$):

$$\hat{M}=\cos\left(\frac{360}{365}(d+10)\right)\cong 0.9088 \tag{12.1.721}$$

where the reader must not forget to convert the content of the parenthesis into radians first!

Hence (converting $12.25°$ into radians):

$$\begin{aligned}\text{EoT}&\cong -9.905\sin(2(0.9088+0.214))-7.655\sin(0.9088)\\&\cong -13.77\text{ minutes }(\;-13\,\text{min}\,46\,\text{sec}\;)\end{aligned} \tag{12.1.722}$$

True solar time (TST) is the sum of the Local Mean Time (LMT) and the Equation of Time:

$$\text{TST}=\text{LMT}+\text{EoT}=13:37:29-00:13:46=13:23:43 \tag{12.1.723}$$

The result is not bad as online calculators give 13:37:26.

When standard clocks (civil time) in Abu Dhabi strike 2:00 PM on January 15 (14:00), the actual solar time is 13:23:43 (depending on the approximations, following the textbooks and the teachers this result can very from 5 to 10 minutes). Consequently, solar noon (12:00:00 TST) on this date occurred nearly half an hour prior to standard noon, exactly at 12:31:53 PM GST.

Finally:

$$\boxed{\begin{aligned}&\text{TST}=\text{LMT}+\text{EoT}=\text{CT}+\Delta\text{DST}+\Delta\text{TZ}+\Delta\text{VLT}_{\text{long.}}+\text{EoT}\\&\quad\cong\text{CT}+\Delta\text{DST}+\Delta\text{TZ}+(\lambda_{\text{local long.}}-\lambda_{\text{GST std.}})\cdot 4\text{ min}/°-9.9\sin(2(\hat{M}+12.25°))-7.65\sin(\hat{M})\end{aligned}} \tag{12.1.724}$$

where (the reader must not forget to convert the content of the parenthesis into radians first!):

$$\hat{M}=\cos\left(\frac{360}{365}(d+10)\right) \tag{12.1.725}$$

12.1.13 Celestial sphere and coordinate systems (positional astronomy)

Definition (#12.1.533): "Azimuthal coordinates", also known as "horizontal coordinates", are a celestial coordinate system used to specify the positions of an object in the sky relative to an observer's horizon. They consist of two angles: "azimuth" (A) and "altitude" (the latter being also named "elevation" h). The azimuth is the angle measured horizontally along the horizon while the altitude (elevation) is the angle measured vertically upwards from the horizon.

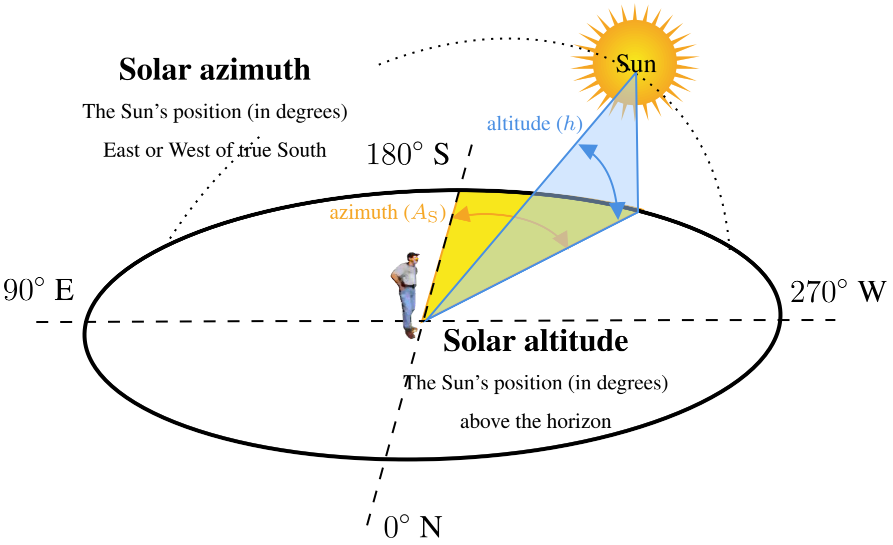

Figure 12.114: **Azimuth and Altitude depicted**

Remark

According to the **old** nomenclature, the azimuth A_S was defined starting from the South towards the West, from $0°$ to $360°$ (SWNE direction). Subsequently, the International Astronomical Union (IAU) changed the definition: Azimuth A_N is now defined from the North towards the East, from $0°$ to $360°$, (NESW direction):

$$A_\text{S} = A_\text{N} + \pi \qquad (12.1.726)$$

or obviously in degrees:

$$A_\text{S} = A_\text{N} + 180° \qquad (12.1.727)$$

Definition (#12.1.534): "Equatorial coordinates" are a celestial coordinate system used to specify the positions of an object in the sky. They are based on the projection of Earth's equator and poles onto the celestial sphere, making them independent of the observer's location and time of observation. The two main components of equatorial coordinates consist of two angles: "right ascension" (α) and "declination" (δ). Right Ascension (α) is like longitude but projected onto the sky, measured in hours, minutes, seconds starting from the first point of Aries (this is the point where the ecliptic - the Sun's apparent path - intersects the celestial equator - an extension of Earth's equator onto the celestial sphere) and Declination (δ) is like latitude in the sky, measured in degrees North or South of the celestial equator.

Observer's Nadir

Figure 12.115: **Right ascension and Declination depicted**

Knowing how to convert between azimuth and equatorial coordinates is important for accurately tracking celestial objects and understanding their positions in the sky. Azimuth (A)/altitude (h) coordinates are observer-centric, meaning they change based on your location and time, while equatorial coordinates right ascension (α)/declination (δ) are fixed with respect to the stars. Converting between these systems allows astronomers to pinpoint object locations regardless of the observer's position and time, and to relate observations made at different times and location.

To convert from azimuth and altitude (horizontal) coordinates to equatorial coordinates (right ascension and declination), we need to know obviously the observer's latitude and the local sidereal time. The conversion involves solving a spherical triangle and using trigonometric equations. Software like Stellarium can also perform this conversion.

The conversion involves a spherical triangle formed by the north celestial pole, the zenith (point directly overhead), and the object in the sky.

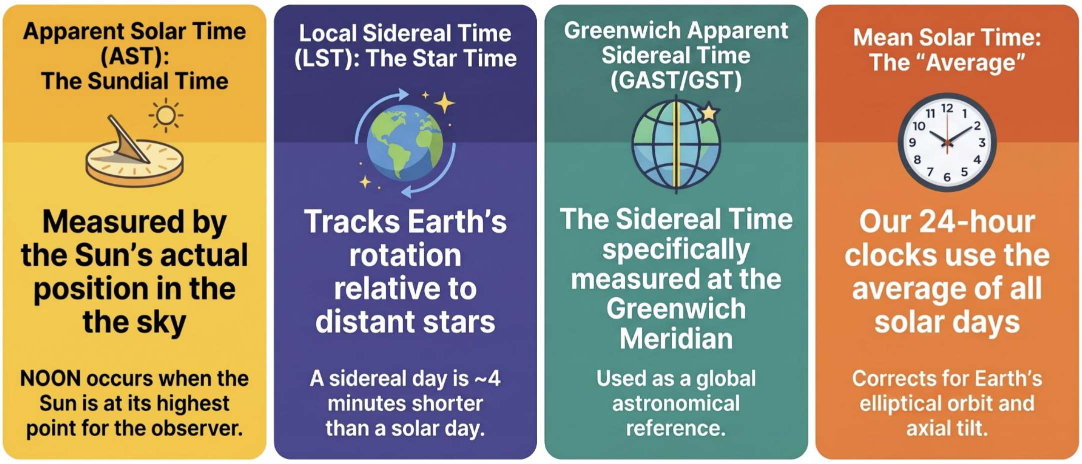
In both cases we need as input or get as output the following elements:

- Observer's latitude (φ)
- Local Sidereal Time (LST) (see definition further below)
- Right ascension (α) and declination (δ) of the object

- Hour angle (denoted depending on the context h, or τ or $\hat{\mathbf{P}}$) of the object (see definition further below)
- Azimuth (A_S) as taken from the South cardinal and altitude (denoted traditionally α) of the object

12.1.13.1 Local Sidereal Time

Definition (#12.1.535): The "Local Sidereal Time" (LST) is a celestial clock used especially by professional astronomers that tracks the Earth's rotation relative to the distant stars, rather than the Sun and it is obviously completely related to the concept of "sideral period" as defined and illustrated at page 5390 (aka sidereal day). It tells us which right ascension is currently crossing our local meridian (see definition page 5462), which is key for determining the best time to observe specific stars or deep-space objects. Unlike True Solar Time (TST), LST runs slightly faster, completing a full cycle in about 23 hours, 56 minutes and 4.0905 seconds (see the illustration at page 5390 to see why). For any location, it's calculated from Greenwich Sidereal Time (GST) adjusted by the local longitude, making it the astronomer's go-to for accurate telescope alignment and sky mapping.



Apparent Solar Time (AST): The Sundial Time
Measured by the Sun's actual position in the sky
NOON occurs when the Sun is at its highest point for the observer.
Local Sidereal Time (LST): The Star Time
Tracks Earth's rotation relative to distant stars
A sidereal day is ~4 minutes shorter than a solar day.
Greenwich Apparent Sidereal Time (GAST/GST)
The Sidereal Time specifically measured at the Greenwich Meridian
Used as a global astronomical reference.
Mean Solar Time: The "Average"

6
7
8
9
10
11
Our 24-hour clocks use the average of all solar days
Corrects for Earth's elliptical orbit and axial tilt.

Viewed from the same location, a star seen at one position in the sky will be seen approximately (excepted for some high velocity stars) at the same position on another night at the same time of day (or night), if the day is defined as a sidereal day. This is similar to how the time kept by a sundial (True Solar Time) can be used to find the location of the Sun. Just as the Sun and Moon appear to rise in the East and set in the West due to the rotation of Earth, so do the stars. Both True Solar Time and Sidereal Time make use of the approximate regularity of Earth's rotation about its polar axis: True Solar Time is reckoned according to the position of the Sun in the sky while Local Sidereal Time is based approximately on the position of the fixed stars on the theoretical celestial sphere.

To calculate the Local Sidereal Time (LST) at a location whose longitude L is known, and at a given day d of the year and hour H (solar) of observation:

- We use the Local Sidereal Time at the Greenwich meridian at a given arbitrary reference time. The ephemeris provides this type of information. Otherwise, we can use the fact that, the January 1, 2000 (gregorian calendar) at 12:00 UTC (nice round modern time), sidereal time at the Greenwich Meridian was 18.697374558 hours. This value used since as reference comes from:

$$\frac{280.46061837^\circ}{15^\circ/\text{h}}=18.697374558\text{ h}. \tag{12.1.728}$$

But obviously you ask yourself where 280.46061837° comes from?!

That angle corresponds for the chosen reference date and time, that Greenwich happened to be pointing 280.46061837° away from the mean equinox.

Remark

The first point of Aries (vernal (spring) equinox), and the first point of Libra (autumnal equinox) are illustrated below:

By definition the "vernal equinox" is the point where the Sun (actually a G2V-type star, aka yellow dwarf) crosses the celestial equator going northward in March. Historically, astronomers chose the vernal equinox as the zero point of right ascension: $\alpha=0^\circ$.

The reader must remember the Earth's rotation is not fixed! The gravitational effects of the Sun and Moon cause a precession (a slow 26,000-year wobble, and a nutation (smaller periodic oscillations). As a result, the equinox is constantly shifting on the celestial sphere. The rate of precession is about $50.29''$ per year or about 1° every 72 years.

So there is no single permanent location of the equinox!

Astronomers therefore distinguish:

- The "mean equinox" where only the smooth precession motion is included and the short-term nutation oscillations are removed.
- The "true equinox" that includes the precession and the nutation so it wiggles slightly around the mean position.

he difference is called the equation of the equinoxes and can reach roughly ± 17 arcseconds.

- We calculate how much time (in solar days and fractions of a solar day) separates the observed instant from the reference instant. Let d be this duration. Each solar day having a duration of 24.06570982441908 sidereal hours, it follows that the sidereal time GST at the Greenwich meridian at the observed instant is, in sidereal hours:

$$\text{GST} \cong 18.697374558 + 24.06570982441908 \cdot d \tag{12.1.729}$$

- To the local Greenwich sidereal time GST at the observed instant is added a time difference due to longitude, namely $L/15$ where L is given in decimal degrees, counted positively when moving towards the East and negatively towards the West. In fact, the 360° of a complete revolution are covered in 24 hours, or 15° per hour:

$$\text{LST} = (\text{GST} + L/15) \text{ modulo } 24 \tag{12.1.730}$$

where for reminder "modulo 24" means that the final result is brought back between 0 hour and 24 hours by adding or differing from an integer multiple of 24 hour.

All these information may be quite abstract. Let us see a use case!

✍**Example:**

An observer is at geographical latitude 50° N and longitude 10° E, on 1991-05-19 (gregorian calendar) at 13:00 UTC. What is the corresponding sidereal time?

We first compute the number of days between the 1991-05-19 13:00 UTC (gregorian calendar) and 2000-01-01 12:00 UTC (gregorian calendar) that is simply equal to $d \cong 3148.958$.

Substituting into the GST formula gives:

$$\text{GST} \cong 18.697374558 + 24.06570982441908 \cdot d \cong 4.779\,\text{h}. \tag{12.1.731}$$

Since the observer is at longitude:

$$\lambda = 10^\circ\mathrm{E} \qquad (12.1.732)$$

the Local Sidereal Time is therefore:

$$\mathrm{LST} = \mathrm{GST} + \frac{\lambda}{15} \cong 4.779 + \frac{10}{15} \cong 5.446\mathrm{h}. \qquad (12.1.733)$$

Converting to hours, minutes, and seconds:

$$5.446\,\mathrm{h.} = 5\mathrm{h}26\mathrm{m}47.55\mathrm{s} \qquad (12.1.734)$$

As 24h. is equal to 360° the corresponding sidereal time is therefore 81.7°.

Definition (#12.1.536): The "hour angle" (denoted h, τ or $\hat{\mathrm{P}}$ depending on the context) of a celestial object is the angular distance between the observer's local meridian and the object's current position in the sky (more precisely its "hour circle"), measured westward along the celestial equator. It essentially tells us how long it's been since the object last crossed your meridian (the imaginary line running from north to south through your zenith). It is usually measured in hours, minutes and secondes (form 0h. to 24h.) or converted into degrees where 1 hour $= 15^\circ$ ($360^\circ = 24$ hours).

For example if the hour angle is 0° the object is right on the local meridian. If the hour angle is negative then the object is East of the meridian and rising, if the hour angle is positive then the object is West of the meridian and setting.

For the definitions above the reader can refer to the figure further below. That may help...

Caution! The detailed proof that we will provide below leads to the famous formulas that you can found on Wikipedia or any other textbook on the topic of positional astronomy. Sadly Wikipedia and those same textbooks don't precise that the results are only approximations because to be able to use spherical trigonometry, we have to assume that the azimuthal observer is like the equatorial observer... at the center of the Earth! This gives a an error of 1.6% for the position of the Moon and 0.0045% and even less for objects further away. This error seems to be negligible however... even for amateur astronomers the approximation is problematic for the observation of occultation of planets.

12.1.13.2 Equatorial coordinates to Azimuthal (horizontal) coordinates

Although the positions of cosmic sources are almost always specified in celestial coordinates, for purposes of observation, it is generally necessary to convert to elevation and azimuth. The conversion formulas between hour angle and declination $(\hat{\mathbf{P}},\delta)$ and elevation and azimuth (h, A_{S}) can be derived by applying the sine and cosine rules for spherical triangles to the system.

Equatorial (red) and horizontal (blue) celestial coordinates

Figure 12.116: **Representation of Equatorial and Azimuthal coordinates**

To convert between the horizontal and equatorial coordinates for an object **X** , we use a spherical triangle often named the "astronomical triangle": Δ**XPZ**, where **Z** is the zenith, **P** is the North celestial pole, and **X** is the object of interest for the observer.

The sides of the purple triangle as visible in the figure above:

- $\overset{\frown}{\mathbf{PZ}}$ is the observer's co-latitude $=90^\circ-\varphi$
- $\overset{\frown}{\mathbf{ZX}}$ is the zenith distance of $=90^\circ-h$

- $\overset{\frown}{\mathbf{PX}}$ is the North polar distance of $90^\circ - \delta$

The angles of the purple triangle as visible in the figure above:

- The angle at **P** denoted $\hat{\mathbf{P}}$ (or τ), the hour angle of **X** (also often denoted H in the literature)
- The angle at **Z** denoted $\hat{\mathbf{Z}}$ is $360^\circ - A_\text{S}$, where A_S is the azimuth of X
- The angle at **X** denoted $\hat{\mathbf{X}}$ named the parallactic angle

We assume we know the observer's latitude φ and the Local Sidereal Time LST (LST may be obtained, if necessary, from Greenwich Sidereal Time and observer's longitude).

Given the right ascension (RA) denoted above α and declination δ, we have Local Hour Angle $\hat{\mathbf{P}} = \text{LST} - \text{RA}$, in hours. We need to convert $\hat{\mathbf{P}}$ to degrees by multiplying that value by 15. Given $\hat{\mathbf{P}}$ the hour angle and δ (declination) and φ (latitude), we require azimuth A_S and altitude h.

By the cosine formula (see section Trigonometry page 2544):

$$\cos(90^\circ - h) = \cos(90^\circ - \delta)\cos(90^\circ - \varphi) + \sin(90^\circ - \delta)\sin(90^\circ - \varphi)\cos(\hat{\mathbf{P}}) \quad (12.1.735)$$

which simplifies to:

$$\sin(h) = \sin(\delta)\sin(\varphi) + \cos(\delta)\cos(\varphi)\cos(\hat{\mathbf{P}}) \quad (12.1.736)$$

By the sines formula (see section Trigonometry page ??):

$$\frac{\sin(\hat{\mathbf{Z}})}{\sin(90^\circ - \delta)} = \frac{\sin(\hat{\mathbf{P}})}{\sin(90^\circ - h)} \quad (12.1.737)$$

As by construction $\hat{\mathbf{Z}} = 360^\circ - A_\text{S}$:

$$\frac{\sin(360^\circ - A_\text{S})}{\sin(90^\circ - \delta)} = \frac{\sin(\hat{\mathbf{P}})}{\sin(90^\circ - h)} \quad (12.1.738)$$

which simplifies to:

$$-\frac{\sin(A_\text{S})}{\cos(\delta)} = \frac{\sin(\hat{\mathbf{P}})}{\cos(h)} \quad (12.1.739)$$

Hence:

$$\sin(A_\text{S}) = -\frac{\cos(\delta)\sin(\hat{\mathbf{P}})}{\cos(h)} \quad (12.1.740)$$

So finally:

$$\boxed{\begin{aligned} h &= \arcsin\left\{\sin(\delta)\sin(\varphi) + \cos(\delta)\cos(\varphi)\cos(\hat{\mathbf{P}})\right\} \\ A_\text{S} &= \arcsin\left\{-\frac{\cos(\delta)\sin(\hat{\mathbf{P}})}{\cos(h)}\right\} \end{aligned}} \quad (12.1.741)$$

Or explicitly:

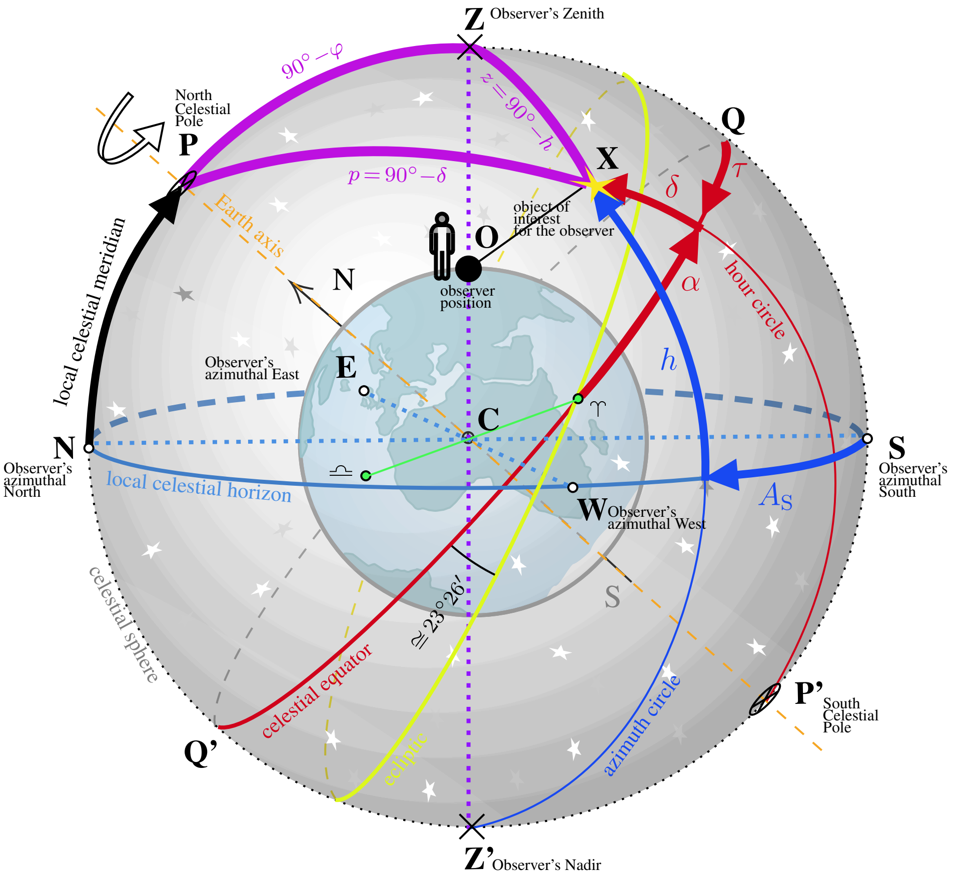
$$\begin{aligned}\text{Altitude angle} &= \arcsin\{\sin(\text{declination angle})\sin(\text{latitude}) \\ &\quad + \cos(\text{declination angle})\cos(\text{latitude})\cos(\text{hour angle})\} \\ \text{Azimuth angle} &= \arcsin\left\{-\frac{\cos(\text{declination angle})\sin(\text{hour angle})}{\cos(\text{altitude angle})}\right\}\end{aligned} \tag{12.1.742}$$

12.1.13.3 Azimuthal (horizontal) coordinates to Equatorial coordinates

Now let us deal with the inverse problem: azimuthal horizontal to equatorial coordinates!

In other words, given the altitude h, the azimuth A_S and the latitude φ what is the hour angle $\hat{\mathbf{P}}$ and the declination δ ?

Again we will use the following figure:



Z Observer's Zenith
90° − φ
z = 90° − h
North Celestial Pole
P
Q
X
p = 90° − δ
δ
τ
object of interest for the observer

W Observer's azimuthal West
S
Observer's azimuthal South
A_S
S
celestial sphere
≃ 23°26′
celestial equator
P' South Celestial Pole
Q'
ecliptic
azimuth circle
Z' Observer's Nadir

φ - latitude
δ - declination
α - right ascension
τ - hour angle

p - polar distance (angular)
A_S - azimuth
h - altitude (elevation)
z - zenith distance (angular)

♎ - First point of Libra
♈ - First point of Aries

Equatorial (red) and horizontal (blue) celestial coordinates

By the cosine formula (see section Trigonometry page 2544):

$$\cos(90^\circ-\delta)=\cos(90^\circ-h)\cos(90^\circ-\varphi)+\sin(90^\circ-h)\sin(90^\circ-\varphi)\cos(\hat{\mathbf{Z}}) \tag{12.1.743}$$

which simplifies to (and also as by construction $\hat{\mathbf{Z}}=360^\circ-A_\text{S}$):

$$\sin(\delta)=\sin(h)\sin(\varphi)+\cos(h)\cos(\varphi)\cos(A_\text{S}) \tag{12.1.744}$$

By the sines formula (see section Trigonometry page **??**):

$$\frac{\sin(\hat{\mathbf{Z}})}{\sin(90^\circ-\delta)}=\frac{\sin(\hat{\mathbf{P}})}{\sin(90^\circ-h)} \tag{12.1.745}$$

As by construction $\hat{\mathbf{Z}}=360^\circ-A_\text{S}$:

$$\frac{\sin(360^\circ-A_\text{S})}{\sin(90^\circ-\delta)}=\frac{\sin(\hat{\mathbf{P}})}{\sin(90^\circ-h)} \tag{12.1.746}$$

which simplifies to:

$$-\frac{\sin(A_\text{S})}{\cos(\delta)}=\frac{\sin(\hat{\mathbf{P}})}{\cos(h)} \tag{12.1.747}$$

Hence:

$$\sin(\hat{\mathbf{P}})=-\frac{\cos(h)\sin(A_\text{S})}{\cos(\delta)} \tag{12.1.748}$$

So finally:

$$\boxed{\begin{aligned}\delta&=\arcsin\left\{\sin(h)\sin(\varphi)+\cos(h)\cos(\varphi)\cos(A_\text{S})\right\}\\ \hat{\mathbf{P}}&=\arcsin\left\{-\frac{\cos(h)\sin(A_\text{S})}{\cos(\delta)}\right\}\end{aligned}} \tag{12.1.749}$$

Or explicitly:

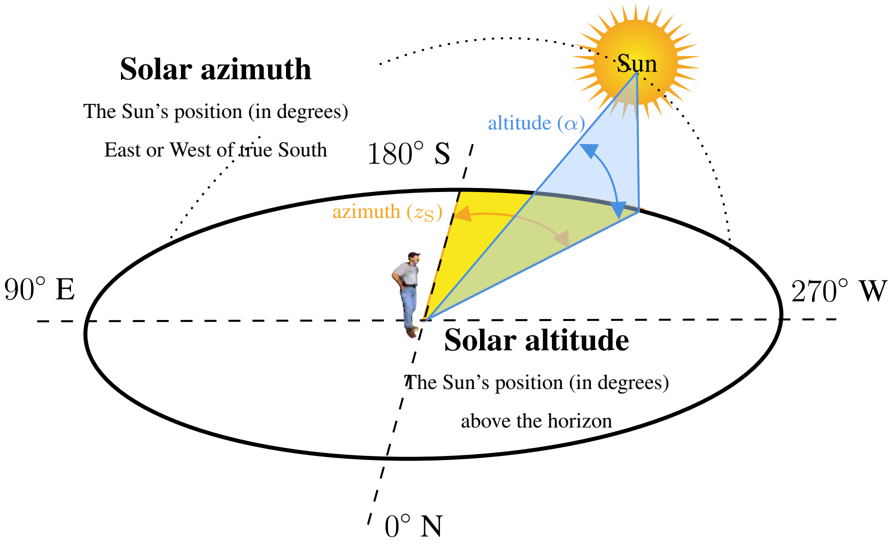
$$\begin{aligned}\text{Declination angle}&=\arcsin\{\sin(\text{altitude angle})\sin(\text{latitude})\\&\qquad+\cos(\text{altitude angle})\cos(\text{latitude})\cos(\text{azimuth})\}\\ \text{Hour angle}&=\arcsin\left\{-\frac{\cos(\text{altitude angle})\sin(\text{azimuth angle})}{\cos(\text{declination angle})}\right\}\end{aligned} \tag{12.1.750}$$

12.1.13.4 Apparent daily path of the Sun (solargraph)

Now that we have defined and studied what are the azimuth and the altitude we can study the path of the Sun (actually a G2V-type star, aka yellow dwarf) in the sky.

The purpose is to determine for an observer at a given latitude, longitude, day and time the real position of the Sun!

For this the main parameters to determine the real path of the Sun from an observer point of view (azimuth $\in [0^\circ, 360^\circ[$ and altitude $\in]-90^\circ, 90^\circ[$) and hence plot a solargraph are de latitude, the longitude, the declination and the hour angle.



Solar azimuth
The Sun's position (in degrees)
East or West of true South
Sun
altitude (α)
180° S
azimuth (z_S)
90° E
270° W
Solar altitude
The Sun's position (in degrees)
above the horizon
0° N

First, let us remind that the declination δ (see page 5431) is a function of the day of the year (d) and given by (remember to convert to parenthesis of the cos into radians to get the right result!):

$$\delta \cong -23.45^\circ \cdot \cos\left(\frac{360}{365}\cdot(d+10)\right) \tag{12.1.751}$$

and $\hat{\mathbf{P}}$ is the hour angle, a function of the time of the day given by (where AST is the Apparent Solar Time - also denoted TST for True Solar Time - studied earlier above):

$$\hat{\mathbf{P}} = (\text{AST}-12)\cdot 15 = (\text{TST}-12)\cdot 15 \tag{12.1.752}$$

The 12 represents the solar noon (the formula uses this to center the hour angle at 0° when the Sun is at its highest point). As at solar noon AST $=12$ the hour angle $\hat{\mathbf{P}}$ is equal to 0°. At morning (AST <12) the hour angle h is negative indicating the Sun is East of the meridian.

For example, at 9:00, $\hat{\mathbf{P}} = (9-12)\cdot 15 = -45^\circ$. At afternoon (AST >12) the hour angle is positive, indicating the Sun is West of the meridian (e.g., at 3:00 PM/15:00, $\hat{\mathbf{P}} = (15-12)\cdot 15 = +45^\circ$).

To plot (and compute) the solargraph, we will use the both relations proved just earlier above:

$$\boxed{\begin{aligned}h&=\arcsin\left\{\sin(\delta)\sin(\varphi)+\cos(\delta)\cos(\varphi)\cos(\hat{\mathbf{P}})\right\}\\A_{\text{S}}&=\arcsin\left\{-\frac{\cos(\delta)\sin(\hat{\mathbf{P}})}{\cos(h)}\right\}\end{aligned}}\qquad(12.1.753)$$

Or explicitly:

$$\begin{aligned}\text{Altitude angle}&=\arcsin\{\sin(\text{declination angle})\sin(\text{latitude})\\&\qquad+\cos(\text{declination angle})\cos(\text{latitude})\cos(\text{hour angle})\}\\\text{Azimuth angle (south)}&=\arcsin\left\{-\frac{\cos(\text{declination angle})\sin(\text{hour angle})}{\cos(\text{altitude angle})}\right\}\end{aligned}\qquad(12.1.754)$$

For this topic, in the literature and on the Internet, the altitude is most of denoted:

$$\boxed{\begin{aligned}\alpha&=\arcsin\{\sin(\delta)\sin(L)+\cos(\delta)\cos(L)\cos(h)\}\\&\cong\arcsin\left\{\sin\left(-23.45^\circ\cdot\cos\left[\frac{360}{365}\cdot(d+10)\right]\right)\sin(L)\right.\\&\left.+\cos\left(-23.45^\circ\cdot\cos\left[\frac{360}{365}\cdot(d+10)\right]\right)\cos(L)\cos((\text{AST}-12)\cdot 15)\right\}\end{aligned}}\qquad(12.1.755)$$

and the solar azimuth angle most often denoted:

$$\boxed{\begin{aligned}z_{\text{S}}&=\arcsin\left\{-\frac{\cos(\delta)\sin(h)}{\cos(\alpha)}\right\}\\&\cong\arcsin\left\{\frac{-\cos(\delta)\sin((\text{AST}-12)\cdot 15)}{\cos\left(\begin{array}{c}\arcsin\left(\sin(L)\sin\left(-23.45^\circ\cdot\cos\left[\frac{360}{365}\cdot(d+10)\right]\right)\right.\\\left.+\cos(L)\cos\left(-23.45^\circ\cdot\cos\left[\frac{360}{365}\cdot(d+10)\right]\right)\cos((\text{AST}-12)\cdot 15)\right)\end{array}\right)}\right\}\end{aligned}}\qquad(12.1.756)$$

For a more general derivation, see the beautiful paper [19].

Let us do an example still by taking the case of Abu Dhabi already used during our study of the True Solar Time.

✍**Example:**

We want to calculate the solar position for Abu Dhabi (UAE) on January 15 at 2 pm (afternoon, i.e. 14:00) local time.

For this calculation, we will use the both relations above to find the solar altitude α and solar azimuth z_{S}, respectively. We will need to find the following parameters:

- L - latitude - Abu Dhabi coordinates are latitude 24.492°N, and longitude 54.358°E

- δ - declination (see page 5431) - It is a function of the day of the year (N) giben for Jan 15 at 2 pm by (don't forget to convert the content of the parenthesis of the $\cos$ in radians!):

$$\begin{aligned}\delta &\cong -23.45^\circ \cdot \cos\left(\frac{360}{365}\cdot(d+10)\right)\\ &\cong -23.45^\circ \cdot \cos\left(\frac{360}{365}\cdot(15.583+10)\right)\cong -21.212^\circ\end{aligned} \tag{12.1.757}$$

  That's very accurate as online calculators give -21.23°.

- h - hour angle - It is a function of the time of the day given by (where AST is the apparent solar time):

$$h=(\text{AST}-12)\cdot 15 \tag{12.1.758}$$

  Applying it on 2 pm, $\text{AST}=13.47$ hr. decimal time (see page 5464 for the detailed calculation) the hour angle will be:

$$h=(\text{AST}-12)\cdot 15=(13.3953-12)\cdot 15\cong 20.929^\circ \tag{12.1.759}$$

  That's quite accurate as online calculators give 22.18°.

Now we can plug these L, δ, and h numbers into the first equation above:

$$\begin{aligned}\sin(\alpha)&=\sin(24.492^\circ)\sin(-21.212^\circ)+\cos(24.492^\circ)\cos(-21.212^\circ)\cos(20.929^\circ)\\ &\cong 0.64\end{aligned} \tag{12.1.760}$$

Hence the elevation (altitude):

$$\alpha\cong 40^\circ \tag{12.1.761}$$

This is quite accurate as online calculators based on Fourier series give between 39.68°. and 43.95°.

For solar azimuth, we use the second relation:

$$\sin(z)=-\frac{\cos(-21.212)\sin(20.929)}{\cos(40^\circ)}=0.45 \tag{12.1.762}$$

Hence:

$$z_{\text{S}}\cong 27^\circ \tag{12.1.763}$$

This is as we know the azimuth taking South as 0° as reference. However must online calculators take the North. Hence to compare this result with these calculator we have to add $+180^\circ$. Hence the North solar azimuth is:

$$z_{\text{N}}\cong 207^\circ \tag{12.1.764}$$

And this is very accurate as online calculators based on Fourier series give instead between 207.04° and 207.11°.

We can use the Sun Path Chart Program calculator of the universityy of Oregon to obtain a complete picture of Sun movement throughout the year. The calculator allows data to be plotted in either orthogonal or polar coordinates. For example, the diagram below was obtained for the same location (Abu Dhabi):

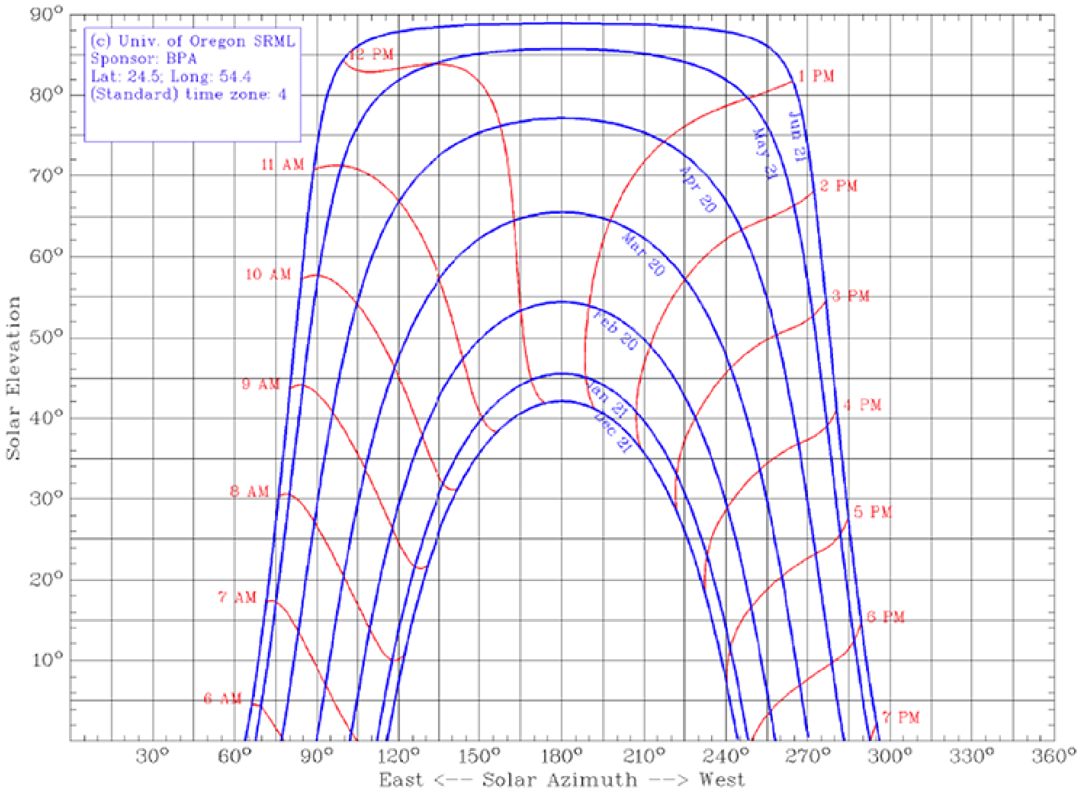


Figure 12.117: **The orthogonal projection of the solar path for Abu Dhabi**

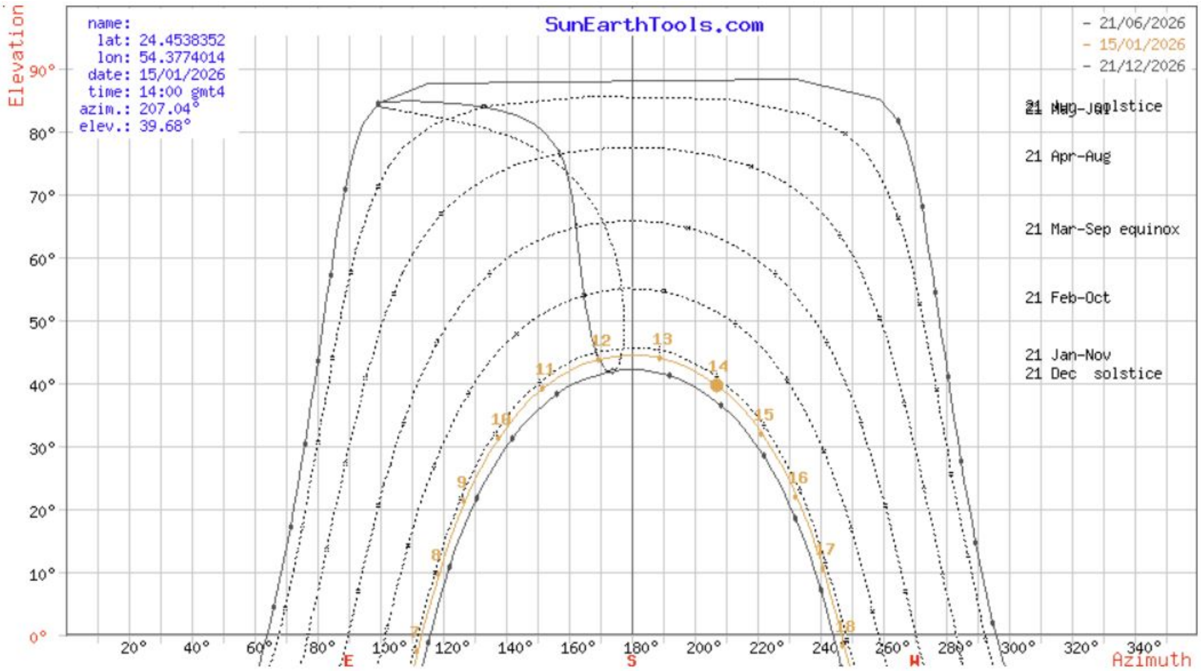
In this diagram, the solar altitude (elevation) is plotted versus solar azimuth, as shown by the blue curves for each date. There are a few representative dates shown, and January 21 is the closest to the calculation example previously given. Note that the solar azimuth is given on the 360° scale, with 180° corresponding to the South. On the Sun Path diagram, the hourly position of the Sun is marked by the red curves. In this particular case, the local standard times are plotted, while a similar diagram can be made in terms of solar time.

Here is also a solargraph of the same location and same place but made with the solargraph SunEarthTools.com:



Based on actual observations captured using a pinhole camera made from a beer can lined with photographic paper, the image below shows sunrises and sunsets over an eight-year period ($2,953$ sunrises and sunsets) from the University of Hertfordshire's Bayfordbury Observatory between 12012 (holocene calendar) and 12020 (holocene calendar):

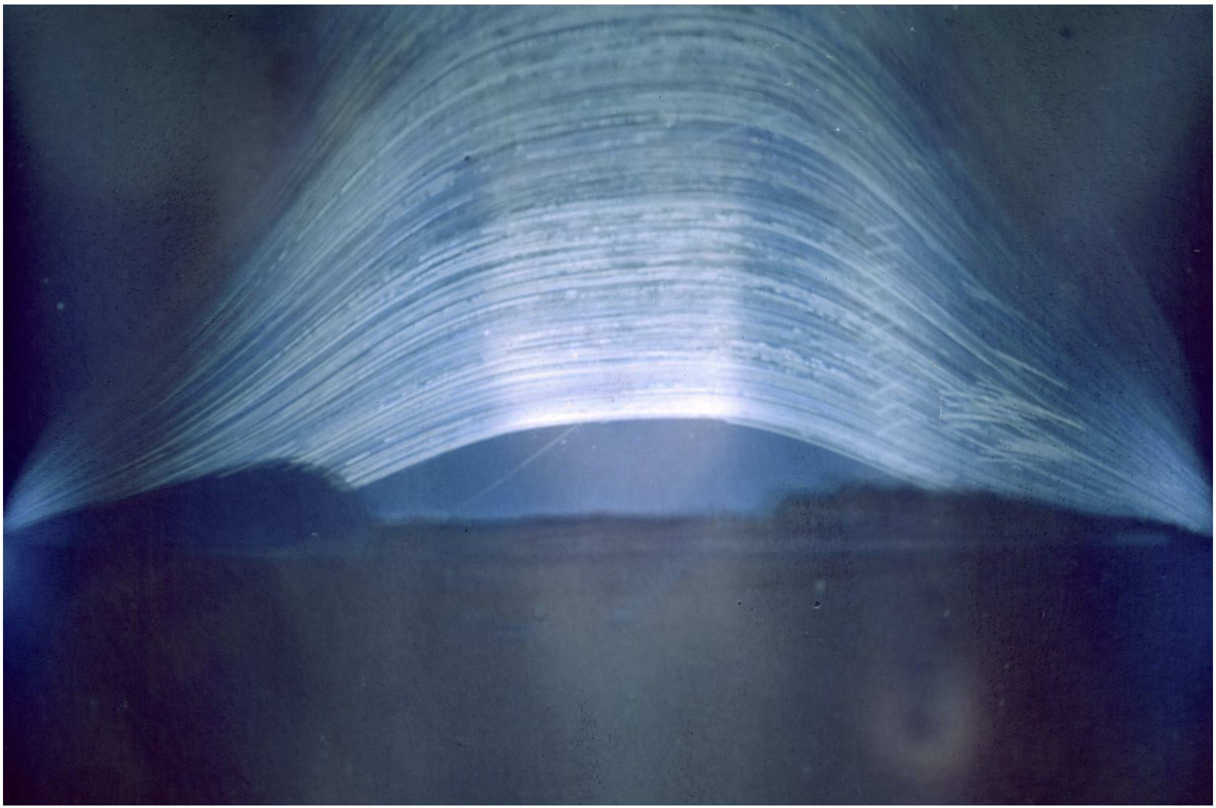


Figure 12.118: Apparent path of the Sun (photo: Regina Valkenborgh)

Remark

A lot of solargraph cameras are made from round tins or cans of some sort (you can even buy them ready-made, like the Solarcan). This curves the paper horizontally, creating a cylindrical projection of the World.

That's the reason for that distinctive look of many of these images, where the Sun's path looks kind of like a mountain rather than the more circular shape the reader may expect.

Here is a more sophisticated pinhole photography that was open only multiple times a day to capture how the analemma itself at different times of the day (form New Year's Eve 12015 to New Year's Eve 12016 - holocene calendar) from the northern hemisphere at about 38-39 degrees North latitude:

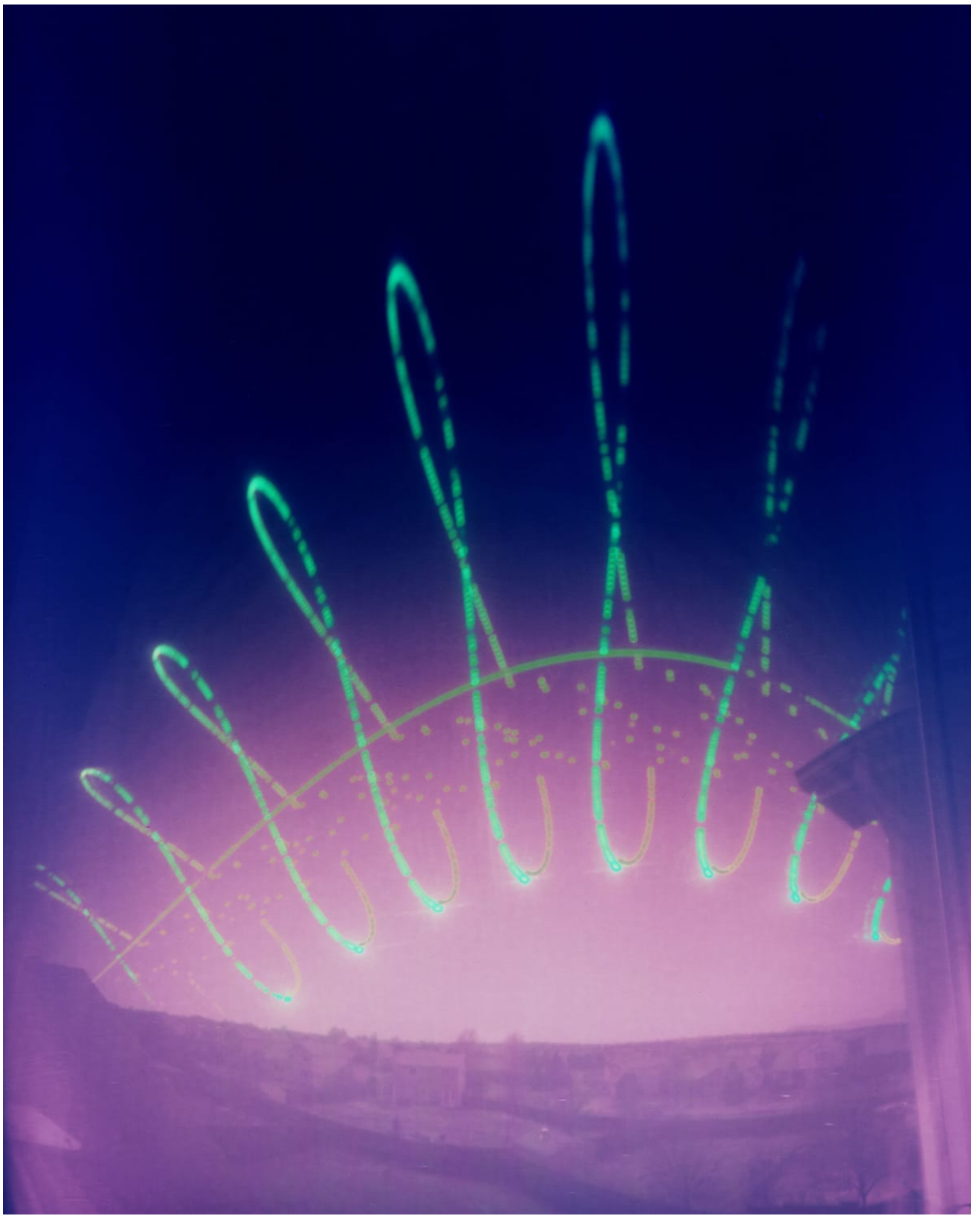

Figure 12.119: **Multiple Solar Analemma With Pinhole Photography**
(photo: SteveR295, source: https://www.instructables.com/Capturing-the-Solar-Analemma-With-Pinhole-Photogra/**)**

Each dot above is a two minutes exposure at the corresponding hour. On one of the equinoxes the photographer stopped the mask in the open position to capture the full streak of the Sun on that day.

Here is a Python™ code to plot a solargraph:

```python
# Author: David Alberto (www.astrolabe-science.fr)
# To run on a Linux environment!

import matplotlib.pyplot as plt
import numpy as np
from math import sin,  cos,  tan, asin, atan, acos

latitude = 24.492  # latitude
couleur_lignes_H = ’indigo’
cmap=plt.get_cmap(’Dark2’)
plt.rcParams.update({"text.usetex": True})
plt.rcParams["font.size"] = 14

phi=np.radians(latitude)
nom_fichier = ’diagramme_azimut_hauteur’ + str(latitude)

hauteurmax=90+23.4-np.degrees(phi) # meridian hight at june 21, for the scale of the height

cosmaxH=-tan(phi)*tan(np.radians(23.4))# maximum hour angle at june 21, for the rise and set hours
if abs(cosmaxH) <=1:
    maxH = np.degrees(acos(cosmaxH))
else:
    maxH = 180
maxH=int(maxH/15)*15

maxAz=np.degrees(acos(-sin(np.radians(23.4)/cos(phi))))# maximum azimuth at sunrise/sunset for the x axis
maxAz=int(maxAz/20+1)*20

def calcul_hauteur(D,H):
    # returns the height of the Sun, according to declination D and hour angle H
    return np.degrees(asin(sin(np.radians(D))*sin(phi)+cos(np.radians(D))*cos(phi)*cos(np.radians(H))))

hauteur_vect = np.vectorize(calcul_hauteur)

def calcul_azimut(D, H) :
    # returns the corrected azimuth
    Az=np.degrees(atan(sin(np.radians(H))/(sin(phi)*cos(np.radians(H))-cos(phi)*tan(np.radians(D)))))
    if Az<0 and H>0:
        Az=Az+180
    elif Az>0 and H<0:
        Az=Az-180
    return Az

azimut_vect = np.vectorize(calcul_azimut)

# Parameters of the plot
fig=plt.figure(figsize=(12, 9), tight_layout=True)
ax=plt.subplot()
plt.xticks(np.arange(-150, 200, 50))  # graduation numbered in azimuth

12.1.14 Eclipses and saros cycles

Definition (#12.1.537): An "eclipse" is an astronomical event which occurs when an astronomical object or spacecraft is temporarily obscured, by passing into the shadow of another body or by having another body pass between it and the viewer. This alignment of three celestial objects is known as a "syzygy". An eclipse is the result of either an *occultation* (completely hidden) or a *transit* (partially hidden). A "deep eclipse" (or "deep occultation") is when a small astronomical object is behind a bigger one.

To eclipse means "to hide". Seen from Earth and at the human naked eye, two celestial bodies can be eclipsed: the Moon and the Sun (actually a G2V-type star, aka yellow dwarf).

For an eclipse to occur, the Earth, the Moon, and the Sun must be somehow aligned:

- If the Earth is approximately located between the Sun and the Moon, there will be a "lunar eclipse"; the latter presents the phase of the Full Moon; the Moon enters the Earth's shadow cone.
- If the Moon is approximately located between the Sun and the Earth, there will be a "solar eclipse"; such an eclipse can only occur during the New Moon phase; the Earth is reached by the Moon's shadow cone.

The different lunar eclipses can be illustrated by:

Figure 12.122: **Composite path of the total lunar eclipse of the 20th January 12019 (holocene calendar) by Benjmanin Lawry (source: www.faceofthedeep.com)**

In real life, under ideal conditions, a total solar eclipse path looks like this (taken with a telescope Explore Scientific ES127 CF and a camera Canon EOS 6D):

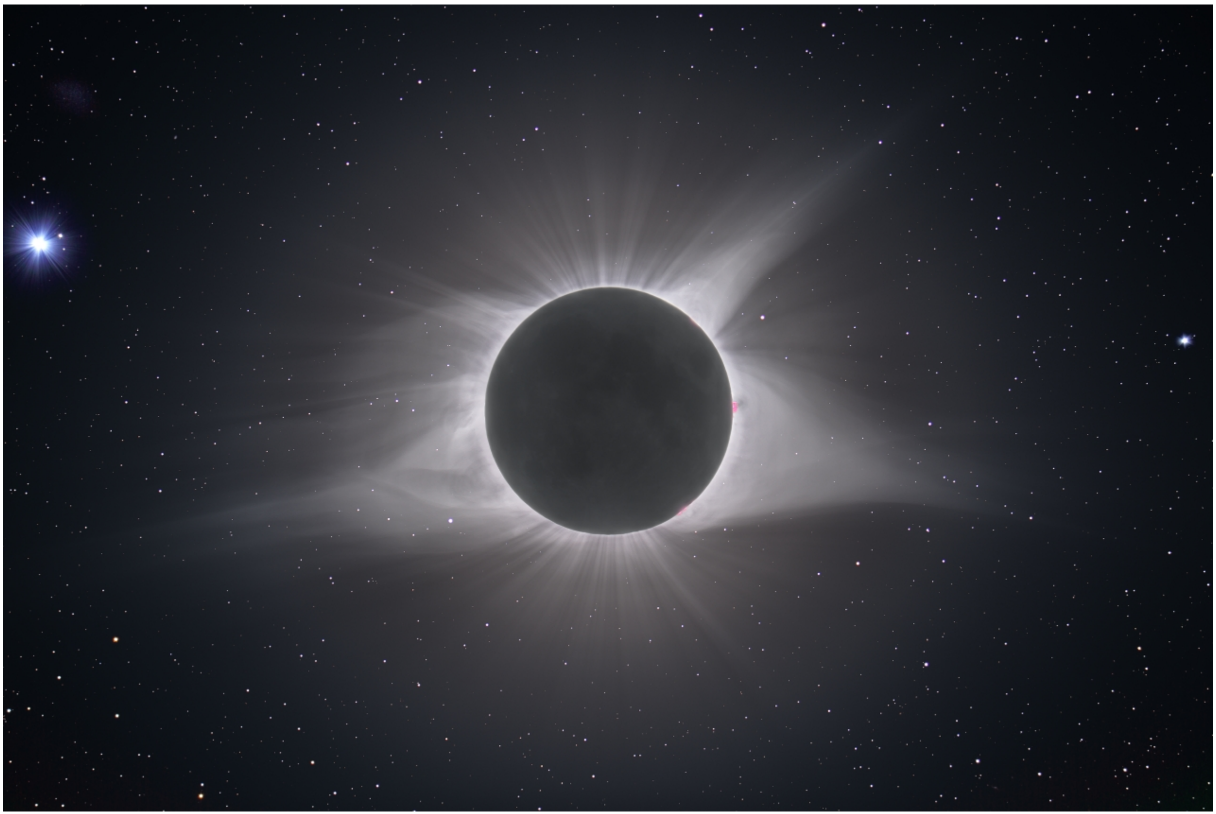

Figure 12.123: **Total solar eclipse of the 21st August 12017 (holocene calendar) by Benjmanin Lawry (source: www.faceofthedeep.com)**

In reality, the conditions for an eclipse to occur are more complicated than the previous diagrams suggest! This complexity is (mostly) because the Moon's mass is quite large relative to the mass of the Earth, so the Earth-Moon barycentre is a significant distance from the centre of the Earth (on average $4,671$ [km] or 0.75 of the Earth's radius). So the Moon's orbit is not well-approximated by an ellipse with the centre of the Earth at one of the focus.

We saw above that for an eclipse to recur, it must happen during the same phase: either the Full Moon phase (for a lunar eclipse) or the New Moon phase (for a solar eclipse). However, this condition regarding the phase is however not sufficient!

We know that the Earth orbits the Sun in a plane named the "ecliptic", which it traverses in approximately one year. Its trajectory is very close to a circle.

Similarly, the Moon orbits the Earth in a relatively elliptical path, which is not contained within the ecliptic.

In the pictures below made with a 200mm diameter Newton telescope and a full opened OD5 filter OD5 and a Canon EOS450d at the focal in Lille (France), we see clearly the influence that has the elliptic orbit as viewed from Earth on the apparent size of the Moon and the Sun:

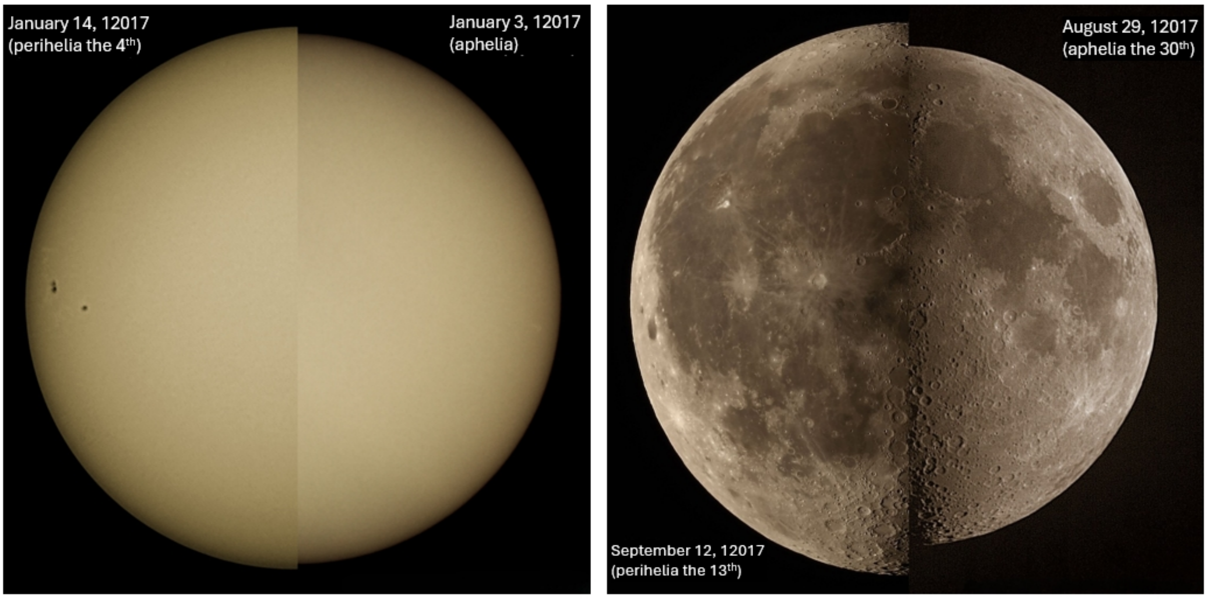

Figure 12.124: Size variation of Sun and Moon because of elliptical orbits at perihelia vs aphelia (source: YouTube La Chaine Astro - cdlc48)

The plane of the Moon's orbit is inclined relative to the ecliptic (by actually approximately $5°$). The Moon's orbit crosses the plane of the ecliptic at two points named the "ascending node" and the "descending node". The alignment of the centers of the Sun, Earth, and Moon can only occur in the vicinity of these nodes. However, the line of nodes in the Moon's orbit is not always aligned with the Sun as visible in the diagram below:

Figure 12.125: Typical naive configurations of solar and moon eclipses

This diagram shows the plane of Earth's orbit (black ellipse) around the Sun (in beige), and for four positions of Earth, the orbital plane of the Moon (in blue) as well as its position on its orbit (grey ellipse). The line of node is shown in green. We have the following:

- In **1**, there is a lunar eclipse: the Moon passes into the Earth's shadow.
- In **2**, there is no eclipse: the Earth's shadow passes "over" the Moon.
- In **3**, there is a solar eclipse: the Moon passes somewhere between the Sun and the Earth and casts its entire shadow (or a part of it) on the latter.
- In **4**, there is no eclipse: the Earth's shadow passes "below" the Moon.

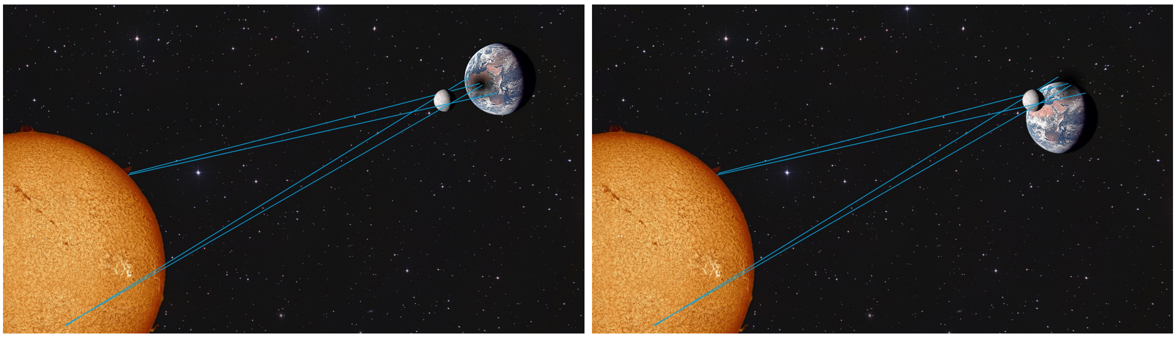
Remark

As we can see in the figure above, the eclipses season is twice a year (but shifted across multiple years because of the behavior of Moon's orbit) and that's why for each year there are two eclipses whose paths are almost symmetrical relative to the equator.

Therefore, for an eclipse to occur it is necessary that:

- The Moon is in a Full Moon phase, or a New Moon phase
- The Moon is in the vicinity of one of its nodes.

That will lead to various types of eclipses and some of which are not intuitive like the solar eclipses that at the poles as illustrated below:



(a) Intuitive typical solar eclipse situation

(b) Less intuitive typical solar eclipse situation

Each of the preceding phenomena is characterized by a specific period that we already know:

- The time interval between two identical phases is named the "synodic period". The synodic period of the Moon is $T_S = 29.530588853$ days.
- The time interval between two passages of the Moon through the same node is named the "draconic revolution". The draconic period has a duration of $T_D = 27.212220817$ days.

Caution! In reality we should take into account other periods to be more rigorous like the nodal precession of 18.6 year cycle (the 5.145° tilt of the lunar orbit rotates, changing the orientation of the orbital) and the apsidal precession of 8.85 year cycle (the ellipse of the Moon's orbit itself rotates, meaning the positions of perigee and apogee change direction). All this because of the torque of Sun on Moon's orbit but also because of Earth's torque as the Earth-Moon barycenter if quite far from Earth's center!

After a given eclipse, in order for a new eclipse of the same nature and occurring under the same conditions to take place, it is necessary that a time interval occur which allows both the return of the same phase and a passage through the same node.

Mathematically, this translates to a duration that will be the smallest common multiple of the synodic and draconic periods. In other words, this time interval T_{saros} (expressed in days) must satisfy both of the following conditions:

$$d = 29.530588853 \cdot n \quad \text{et} \quad d = 27.212220317 \cdot m \tag{12.1.765}$$

where m and n are integers. A "saros" is by definition a multiple of T_{saros}.

This search is similar to that of a least common multiple (LCM) that we have studied in the section of Number Theory at page 347. The difference lies in the fact that the LCM is defined within the set of integers, whereas in the case we are considering here, the synodic and draconic periods are arbitrary real numbers. Because of this difference, the method for finding the least common multiple of the two periods cannot be performed by prime factorization, as in the case of the LCM.

To determine the nearest n and m let us use the techniques see during our study of continued fraction in the section of Number Theory at page 369.

To do this, we look for two integers x and y such that:

$$x\cdot T_D=y\cdot T_S \tag{12.1.766}$$

or:

$$\frac{x}{y}=\frac{T_S}{T_D} \tag{12.1.767}$$

Now, let us choose the approximate quotient of T_S by T_D as:

$$\frac{T_S}{T_D}\cong 1.08519584093 \tag{12.1.768}$$

The continued fraction method allows us to find a rational "best approximation" of 1.08519584093 in the sense that there is no more precise one with a denominator less than or equal to it:

$$\frac{29.5305888532}{27.212220817}=1+\cfrac{1}{11+\cfrac{1}{1+\cfrac{1}{2+\cfrac{1}{1+\cfrac{1}{4+\cfrac{1}{3+\cfrac{1}{5+\cfrac{1}{1+\ldots}}}}}}}} \tag{12.1.769}$$

The 8th-order reduced form of T_S/T_D is therefore: $(1;11,1,2,1,4,3,5,1)$.

The possible values of x and y will be successively:

$$\begin{gathered}\frac{x}{y}=1\\ \frac{x}{y}=1+\frac{1}{11}=\frac{12}{11}\cong 1.09090909\\ \frac{x}{y}=1+\frac{1}{11+\frac{1}{1}}=\frac{13}{12}\cong 1.08333333\\ \frac{x}{y}=1+\frac{1}{11+\frac{1}{1+\frac{1}{2}}}=\frac{38}{35}\cong 1.085714285\\ \frac{x}{y}=1+\frac{1}{11+\frac{1}{1+\frac{1}{2+\frac{1}{1}}}}=\frac{51}{47}\cong 1.085106382\\ \frac{x}{y}=1+\frac{1}{11+\frac{1}{1+\frac{1}{2+\frac{1}{1+\frac{1}{4}}}}}=\frac{242}{223}\cong 1.085201794\end{gathered} \tag{12.1.770}$$

So a first "best approximation" of T_S/T_D is obtained for $x=242$ and $y=223$ (the difference is less than 6.10^{-6}).

In other words, a given eclipse will recur after 223 lunar months (or 242 draconic revolutions).

Since a lunar cycle lasts 29.5305888532 days, this interval will be:

$$T_{\text{saros}}\cong 29.5305888532\cdot 223=6585.321314\,\text{days} \tag{12.1.771}$$

Remark

If, instead of calculating the saros from the lunation (synodic revolution), we had started from the draconic revolution, we would have found a very slight difference (52 minutes), which does not affect the result found above.

6585.3 is therefore an approximate value expressed in days: therefore, there are approximately 6585 days + 0.3 days between two eclipses of the same type occurring under the same conditions. The mean solar year is 365.2596 days. Let's find out how many years are contained in 6585.3 days:

$$T_{\text{saros}}=\frac{6585.3}{365.2596}\cong 18.029\,\text{mean solar years} \tag{12.1.772}$$

This means that the duration of 6585.3 (approximation of an approximation of an approximation of an approximation....) days represents slightly more than 18 years. Let's clarify a bit.

We have $18 \cdot 365 = 6570$. Therefore, there is, a priori, a surplus of $6585.3 - 6570 = 15.3$ days. Since within an 18-year period there may be 3, 4, or 5 leap years, we must add 3, 4, or 5 days to 6570. We thus get:

- $6585.3 - (6570 + 3) = 12.3$ days
- $6585.3 - (6570 + 4) = 11.3$ days
- $6585.3 - (6570 + 5) = 10.3$ days

Therefore, the time difference between two eclipses of the same type and with identical conditions is: 18 years plus 10, 11, or 12 days and 0.3 days, that is, approximately 8 hours. This last result can be interpreted as meaning that the Earth will have rotated approximately 8 hours longer, or 120°, and therefore the eclipse will not occur again in the same location on Earth (this observation applies primarily to solar eclipses).

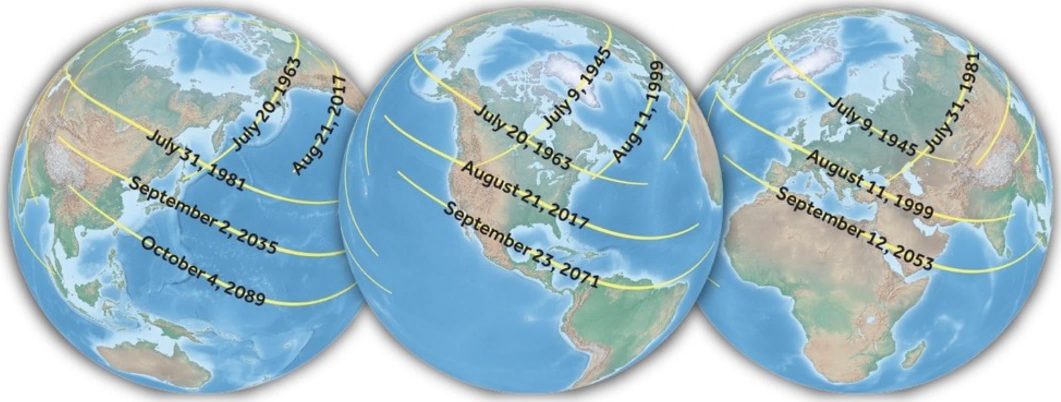


Figure 12.127: **Some saros cycles according to the gregorian calendar (credit: Michael Zeiler, GreatAmericanEclipse.com)**

The term "saros" refers to this period of 18 years and 10 days (possibly 11 or 12, to account for leap years) at the end of which eclipses recur in the same order, at the same lunar cycles, with very similar characteristics. It is actually unknown (contrary to what is often said) whether the Ancients were familiar with the saros. This term was first used by Edmund Halley (11656-11742 according to holocene calendar), who misinterpreted an ancient text (*The Suda*). Among the Chaldeans, the word "saros" designates the Universe, or a period of 222 lunar months, that is, 18 years and 6 months, with a year of 12 lunar months. The ancient text used the word saros for a duration that had nothing to do with eclipses!

Any two eclipses separated by one Saros cycle share very similar geometries. They occur at the same node with the Moon at nearly the same distance from Earth and at the same time of year. However, the eclipses do not occur at the same locations on Earth mainly because the period is not a whole number; it includes an odd 0.3 day or 8 hours a proven earlier above. This means that Earth must rotate an additional 8 hours on the next eclipse. This is equal to 120° of longitude and so each successive eclipse is shifted that much westwards. However, three successive Saros cycles make 360° so, an eclipse returns to the same approximate geographic region every 54 years and 34 days. This period of 3 saroses is named an "exeligmos" (a Greek word, means turning of the wheel). We can see an exeligmos in the figure above for example for the two solar eclipses of the 9th July 1945 and the 11th August 1999 (according to the gregorian calendar).

Remark

Carbondate, Illinois (USA) was in the center of the path of totality for the 2017 (gregorian calendar) solar eclipse and was also in the path for the solar eclipse of the 8th April 2024 even though the pathways are totally different. The paths just happen to cross right there. This is extremely rare.

The method of determination used earlier above, which is similar to finding the least common multiple (LCM), gives a very good approximate value; to obtain more precise value for the eclipse predictions (time and position) we use nowadays highly elaborated numerical simulations like the VSOP2013 model (French: *Variations Séculaires des Orbites Planétaires*). We can also use statistical methods to infer about mean properties of eclipses like Jean Meeus, that in his excellent *Mathematical Astronomy Morsels*, p. 91 (on of the five volumes for a total of the $1,600$ pages...), writes :

"*We then, finally, obtain the following mean frequencies for any given point at the Earth's surface: a total eclipse once in* 375 *years, an annular eclipse once in* 224 *years, which, by combination, gives an annular or a total eclipse every* 140 *years in average for a place chosen at random. Because our results are based on a sample of observable eclipse, they are subject to uncertainty of about* 16 *years' standard error for total eclipses,* 7 *years for annular, and* 4 *years for both. Further error may arise because of the limited number of points on the Earth's surface used in the analysis.* "

While total solar eclipses occur somewhere on Earth in average every 18 months, their paths rarely cross the same spot twice in a human lifetime. However, partial eclipses are more frequent, and a location might see another eclipse within a few decades.

According to calculations done by astronomical mathematicians Jean Meeus and Fred Espenak, in the $5,000$ year period between the years 2000 BCE and 3000 CE (a.k.a 'AD' according to gregorian calendar) there will be $12,064$ lunar eclipses. Of these, $3,479$ will be total lunar eclipses - the rest will be either partial (in which the central part of Earth's shadow, the umbra, does not completely cover the face of the moon) or penumbral (in which only the outer shadow, the penumbra, touches the Moon).

That makes an average of:

$$\frac{12,064}{5,000}\cong 2.4128 \tag{12.1.773}$$

lunar eclipses per year and...:

$$\frac{3,479}{5,000}\cong 0.6958 \tag{12.1.774}$$

total lunar eclipses per year. Hence one in average every 17.14 months.

During the $5,000$ years period from 2000 BCE to 3000 CE (a.k.a 'AD' according to gregorian calendar), Earth will experience $11,898$ eclipses of the Sun. The statistical distribution of solar eclipse types for this interval is as follows: $4,200$ partial solar eclipses, $3,956$ annular eclipses, $3,173$ total solar eclipses, and 569 hybrid solar eclipses (source: NASA/TP-2006-214141 PDF, 648 pages, october 12006).

That makes an average of:

$$\frac{11,898}{5,000} \cong 2.3796 \tag{12.1.775}$$

solar eclipses per year and...:

$$\frac{3,173}{5,000} = 0.6346 \tag{12.1.776}$$

total solar eclipses per year. Hence one in average every 17.14 months.

At the beginning of the 119th century (holocene calendar), the Italian mathematician and astronomer Giovanni Plana published an extraordinary and highly detailed treatise in French entitled *Théorie du mouvement de la Lune*. Spanning approximately 2,800 pages across three volumes, the work presents a complete mathematical treatment of lunar motion, including virtually all intermediate derivations and computational steps. Plana developed a sophisticated analytical model of the Moon-Earth-Sun three-body problem, enabling significantly more accurate predictions of lunar and solar phenomena, including eclipses, than those obtainable from empirical schemes such as the Saros cycle. To achieve this level of precision, he carried perturbation calculations to unprecedented detail, extending Taylor series expansions and Fourier-type trigonometric developments to fifth-, sixth-, and even seventh-order terms, making the treatise one of the most ambitious works of celestial mechanics ever written.

Almost thirty years later the French astronomer and mathematician Charles-Eugène Delaunay tried during twenty years to create a model of the movement of the Moon using hamiltonian mechanics, perturbation theory and other clever mathematical techniques and wrote two volumes on the topic for a total of approximately 1,800 pages (see [134]). And he failed ! Because he didn't knew at his time (it is Henri Poincaré that proved it later) that the Moon-Earth-Sun system is a three body chaotic system! His infinite series expression for finding the position of the Moon converged too slowly to be of practical use but was a catalyst in the development of functional analysis and computer algebra.

12.1.15 Lagrange Points

A "Lagrange point" (denoted by L), or "libration point" is a position in space where the gravitational fields of two bodies in orbit around each other, and of substantial masses, combine to provide an equilibrium point to a third body of negligible mass, such that the relative positions of the three bodies are fixed.

We will in the developments that follow take time to prove (as best as we can...) that such points are at the number of 5 denoted L1 to L5 respectively.

It may be helpful to make a presentation of these points and their properties before going through the mathematical part. This may help in understanding the subject.

We will immediately consider the following diagram:

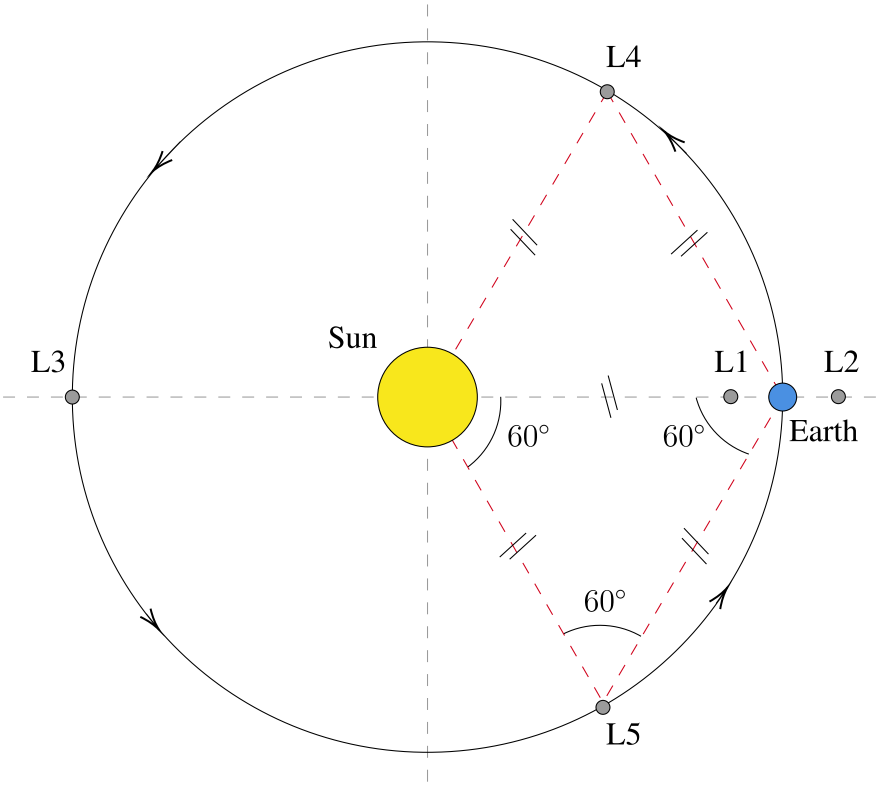

Figure 12.128: Representation of the five Lagrangian point in the Sun-Earth system

There are five Lagrange points:

L1: On the line defined by the both masses between them (this is the most easy point to interpret intuitively: it is for example the point where the gravitational attraction of the Sun is compensated by that of the Earth).

✍**Example:**

We consider an object orbiting around the Sun, closer to the latter than the

Earth but on the same line. This object undergoes a solar gravity greater than that of Earth, and therefore spins faster around the Sun (actually a G2V-type star, aka yellow dwarf) than does the Earth. But Earth's gravity partially counteracts that of the Sun, which slows it down. The more we approaches this object of the Earth the more this counteract effect is important. At some point, the point L1, the angular speed of the object becomes exactly equal to that of the Earth.

L2: On the line defined by the both masses, beyond the smaller (a bit less intuitive as is the point where the cumulative effect of the Sun and Earth will compensate the centrifugal (fictional) force).

✍**Example:**

The principle is similar to the previous case, but on the other side of the Earth. The object should rotate more slowly than Earth because the solar gravity is lower, but the extra gravitational field due to the Earth tends to accelerate it. At some point, the point L2, the object rotates at exactly the same angular velocity as the Earth around the Sun.

L3: On the line defined by the two masses, beyond the larger (intuitive based on physical considerations: it is clear that an object diametrically opposite to the Earth relatively to the Sun would have the same orbital period as the Earth and therefore would be fixed relative to the Earth-Sun system).

✍**Example:**

Identically to the L2 point, there exists a point a little further away than the Earth relatively the Sun, where a negligible mass object would be in equilibrium.

L4 & L5: On the apexes of two equilateral triangles whose base is formed by the two masses.

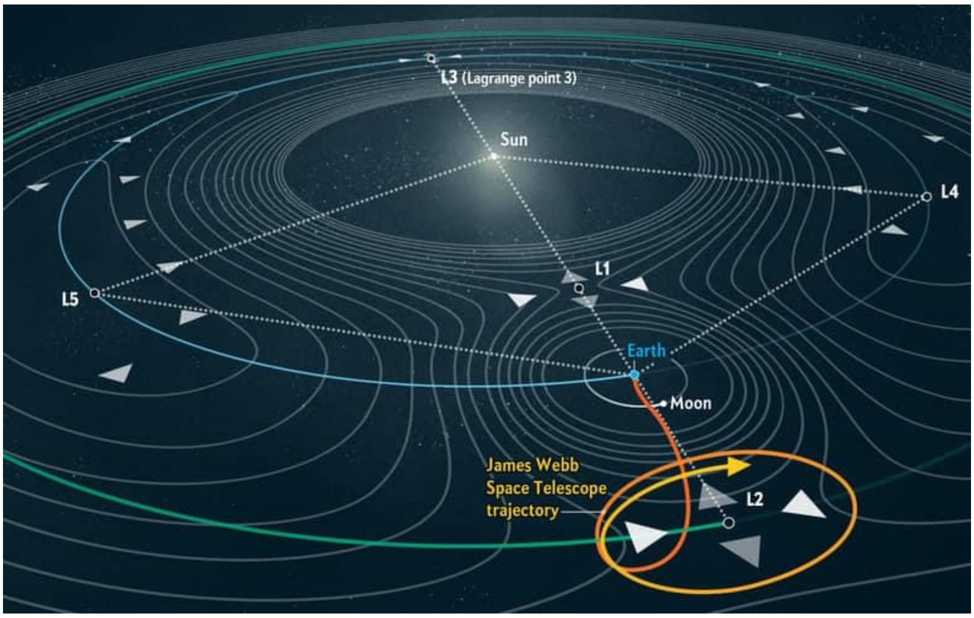
✍**Example:**

This is a subtle balance between the centripetal force exerted by the two main masses and the centrifugal (fictional) force of the masses considered at the points of interest. L4 is ahead of the smaller mass in its orbit around the large one, and L5 is late. These two points are sometimes named "triangular Lagrange points" or "Trojans point".

Remarkably, the last two points do not depend on the relative masses of the two bodies as we will prove it.

For the first three Lagrangian points, stability appears only in the plane perpendicular to the line occupied by the two masses. For example, for the L1 point, if we move an object perpendicular to the line between the two masses, the two gravitational forces will play to bring it back to the starting position. The equilibrium is stable. However, if we move it near to one the two masses, then the field of that latter will prevail over the other and the object will tend to get closer. The equilibrium is unstable. For L4 and L5 points, stability is obtained due to Coriolis forces acting on the objects moving away from the point.

Given the stability issues given above, we have no natural object around point L1, L2 and L3 at least in the Solar System. However, they still represent an interest in scientific achievements because they allow savings of fuel for orbit control and attitude. This is not valid for point L3, due to its distance from Earth which only application what that utopic one made by Sci-Fi and comic books authors that place an Anti-Earth twin-planet but which mass was too high in relation to the theory stated above. However, space missions use L1 and L2: the case of the probe SOHO since 11995 according to holocene calendar (Solar and Heliospheric Observatory) a Sun observation station located at L1 (1.5 million kilometres from Earth) or MAP (Wilkinson Microwave Anisotropy Probe) satellite or Planck satellite (to study the cosmic microwave background at 2.7 [K]) close to the point L2 as will be the James Webb telescope in 12021 (the radiation of Earth there are relatively low and those of the Sun attenuated by the Earth which do a screening effect).



The points L4 and L5 being stable, we find many natural celestial objects. In the Sun-Jupiter system, hundreds of asteroids, known as "Trojan asteroids", clump there together (around $1,800$ identified in April 12005 according to holocene calendar). We count also some in the Neptune-Sun systems and Mars-Sun system. Curiously, it seems that the Saturn-Sun system is not be able to accumulate such celestial objects because of the Jovian disruption. We also find objects to these points in the Saturn planetary system of Saturn: Saturn-Tethys with Telesto and Calypso with the L4 and L5 points and Saturn-Dione with Helen to the point L4 and Pollux at the L5 point. In the Sun-Earth system, there is no known large object to the Trojans points, but it was discovered a slight over-abundance of dust in 11950 (holocene calendar). Slight dust clouds are also present for the system Earth-Moon; this make scientific abandon the idea to place there a space telescope as it was envisaged once.

Strictly speaking, these 5 points exist only for two bodies in circular rotation one around the other. Once the orbit of the two bodies is elliptical, these points are no longer equilibrium points. In practice, if the orbit is slightly elliptical, as is the case for real planets, we can find stable orbits oscillating not departing too much of the regions corresponding to the Lagrangian points and this is well named a "halo orbit". Therefore the halo orbit is a periodic, three-dimensional orbit near the L1, L2 or L3 Lagrange points in the three-body problem of orbital mechanics. Most three-body systems are chaotic however some are stable! The system that we will study right now is such a stable system named "restricted three-body problem".

In general we consider the problem of three point masses (ma with position vectors $\vec{r}_a$ for $a=1,2,3$) moving under their mutual gravitational attraction. This system has 9 degrees of freedom, whose dynamics is determined by 9 coupled second order nonlinear ODEs:

$$m_a\frac{\mathrm{d}^2\vec{r}_a}{\mathrm{d}t^2}=\sum_{b\neq a}Gm_am_b\frac{\vec{r}_b-\vec{r}_a}{|\vec{r}_b-\vec{r}_a|^3}\quad\text{for } a=1,2\text{ and }3 \tag{12.1.777}$$

As before, the three components of momentum:

$$\vec{p}=\sum_a m_a\dot{\vec{r}}_a \tag{12.1.778}$$

three components of angular momentum:

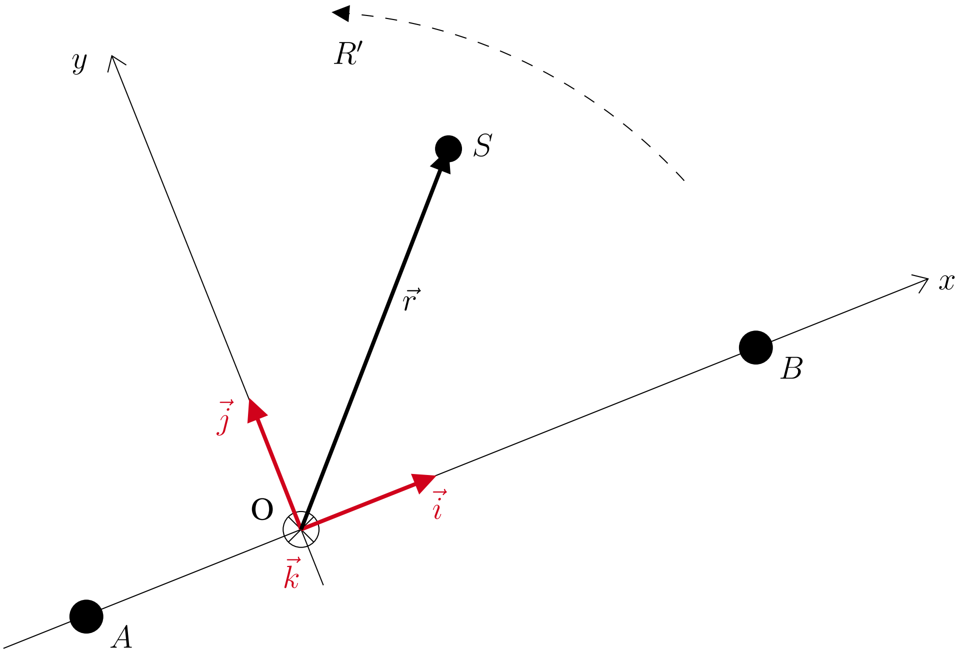
$$\vec{L}=\sum_a \vec{r}_a\times\vec{p}_a \tag{12.1.779}$$

and energy:

$$E=\frac{1}{2}\sum_{a=1}^{3}m_a\dot{\vec{r}}_a^2-\sum_{a<b}\frac{Gm_am_b}{|\vec{r}_a-\vec{r}_b|}\equiv T+V \tag{12.1.780}$$

Although the Lagrange point is just a point in empty space (assumed as because we will see during study of quantum field theory that there are not such things as "empty space"), its peculiar characteristic is that it can be orbited by a special kind of orbit named "Lissajous orbit". The first mission to use a halo orbit was ISEE-3, launched in 11978 (holocene calendar). It travelled as we already mention to the Sun–Earth L1 point and remained there for several years. The next mission to use a halo orbit was in fact Solar and Heliospheric Observatory (SOHO), a joint ESA and NASA mission to study the Sun, which arrived at Sun–Earth L1 in 11996 (holocene calendar). It used an orbit similar to ISEE-3.

So we will consider in space an isolated system of two bodies A and B, of mass M_A and M_B in gravitational interaction. These two bodies are assumed to be in circular orbit (for simplicity!) one around the other, in the manner of a two-star system (binary system) or a planet-satellite like system (Saturn-Titan example). We seek to determine if there are relative equilibrium point to the system of the two rotating body for a third body also in circular motion in the same plane (of sufficiently low mass to avoid disturbing the motion of the system of the two main bodies).



Let O be the centroid (see section Classical Mechanics page 3213) of these two stars (or celestial objects in general). Let us consider a Galilean reference frame (in rectilinear and uniform motion therefore !) or origin O. Compared to this reference frame, we assume that the axis AB rotates at a constant angular velocity ω of fixed axis $\vec{k}$ (perpendicular to the page in the figure and directed towards the reader) and that the distances $r_A=\overline{\text{AO}}$ and $r_B=\overline{\text{BO}}$ also remain constant.

We know from our study of Classical Mechanics that a circular motion the centrifugal (fictional) force is given by (see page 3388):

$$F=ma=m\frac{v^2}{R}=m\frac{(\omega R)^2}{R}=m\omega^2 R \tag{12.1.781}$$

So we have (equilibrium between (fictional) centrifugal and centripetal forces) to guarantee the equilibrium:

$$M_A\omega^2 r_A=\frac{GM_AM_B}{(r_A+r_B)^2} \qquad \text{and} \qquad M_B\omega^2 r_B=\frac{GM_AM_B}{(r_A+r_B)^2} \tag{12.1.782}$$

By simplifying and summing these two relations: By simplifying and summing these two relations:

$$\begin{aligned}\omega^2 r_A+\omega^2 r_B&=\frac{GM_A}{(r_A+r_B)^2}+\frac{GM_B}{(r_A+r_B)^2}\\ \rightarrow\omega^2&=\frac{G(M_A+M_B)}{(r_A+r_B)^3}=\frac{G(M_A+M_B)}{R^3}\end{aligned} \tag{12.1.783}$$

with in what will follow $AB=r_A+r_B=R$.

Let us consider a rotating reference frame R' linked to our stars as shown in figure above: $\vec{i}$ will be a collinear unit vector to AB, $\vec{j}$ a unit vector perpendicular to $\vec{i}$ and in the rotating plane of the planets and finally $\vec{k}=\vec{i}\times\vec{j}$ collinear to $\vec{\omega}$.

We consider in this rotating frame (with stars) a third star S of mass m negligible relatively to M_A and M_B, subject to the gravitational attraction of A and B.

Now let us denote by $\vec{a}_{R'}$ the acceleration of S with respect to R', $\vec{v}_{R'}$ its speed and $\vec{e}_r$ the collinear unit vector to $\overrightarrow{\mathrm{O}S'}$ where S' is the projection of S in the plane $\mathrm{O}xy$, and $r=\overline{\mathrm{O}S'}$ (in the figure above, we assumed S in the plane $\mathrm{O}xy$, so S and S' are indistinguishable).

S is thus subjected to two forces, one $\vec{F}_A$ directed along A and the other $\vec{F}_B$ directed along B, forces of respective intensities :

$$\vec{F}_A=-\frac{GM_Am}{\overline{AS}^3}\overrightarrow{AS} \qquad \text{and} \qquad \vec{F}_B=-\frac{GM_Bm}{\overline{BS}^3}\overrightarrow{BS} \tag{12.1.784}$$

In a Galilean reference frame, these two forces apply to S an acceleration given by the law of composition of accelerations in a circular reference frame (see section Classical Mechanics page 3383):

$$\frac{1}{m}(\vec{F}_A+\vec{F}_B)=\vec{a}_a=\vec{a}_e+\vec{a}_r+2\vec{\omega}\times\vec{v}_r+\frac{\mathrm{d}\omega}{\mathrm{d}t}\times\vec{r}+\vec{\omega}\times(\vec{\omega}\times\vec{r}) \tag{12.1.785}$$

But, in our configuration the pulsation (radial velocity) is assumed constant and the drive acceleration is zero since we assumed R' as the main repository. Therefore it comes:

$$\frac{1}{m}(\vec{F}_A+\vec{F}_B)=\vec{a}_r+2\vec{\omega}\times\vec{v}_r+\vec{\omega}\times(\vec{\omega}\times\vec{r})=\vec{a}_{R'}+2\vec{\omega}\times\vec{v}_r+2\vec{\omega}\times\vec{v}_r+\vec{\omega}\times(\vec{\omega}\times\vec{r}) \tag{12.1.786}$$

We also have:

$$\vec{\omega}=\begin{pmatrix}0\\0\\\omega_z\end{pmatrix} \qquad \vec{\omega}=\begin{pmatrix}r_x\\r_y\\0\end{pmatrix} \tag{12.1.787}$$

where according to the figure all components are positive. The calculation of the cross product then gives (see section Vector Calculus page 1830):

$$\vec{\omega}\times(\vec{\omega}\times\vec{r})=\begin{pmatrix}-\omega^2r_x\\-\omega^2r_y\\0\end{pmatrix}=-\omega^2\begin{pmatrix}r_x\\r_y\\0\end{pmatrix}=-\omega^2\|\vec{r}\|\frac{\vec{r}}{\|\vec{r}\|}=-\omega^2r\vec{e}_r \tag{12.1.788}$$

So finally:

$$\frac{1}{m}(\vec{F}_A+\vec{F}_B)=\vec{a}_{R'}+2\vec{\omega}\times\vec{v}_r+\vec{\omega}\times(\vec{\omega}\times\vec{r})=\vec{a}_{R'}+2\vec{\omega}\times\vec{v}_r-\omega^2r\vec{e}_r \tag{12.1.789}$$

Let us rather write this relation into the form:

$$\vec{a}_{R'}=-\frac{1}{m}(\vec{F}_A+\vec{F}_B)+\omega^2r\vec{e}_r-2\vec{\omega}\times\vec{v}_r \tag{12.1.790}$$

We then obtain, by projecting on the three axes x, y and z, the derivatives taken with respect to time t the following system:

$$\begin{aligned}x''&=-\frac{GM_A}{\overline{AS}^3}(x+r_A)-\frac{GM_B}{\overline{BS}^2}(x-r_B)+\omega^2x-2\omega y'\\y''&-\frac{GM_A}{\overline{AS}^2}y-\frac{GM_B}{\overline{BS}^3}y+\omega^2y+2\omega x'\\z''&=-\frac{GM_A}{\overline{AS}^3}z-\frac{GM_B}{\overline{BS}^3}z\end{aligned} \tag{12.1.791}$$

with:

$$\overline{AS}=\sqrt{(x+r_A)^2+y^2+z^2} \qquad \text{and} \qquad \overline{BS}=\sqrt{(x-r_B)^2+y^2+z^2} \tag{12.1.792}$$

so that the coordinates (x,y,z) of the point S are those of an equilibrium point, then it is trivial that in the rotating frame with the stars A and B that:

$$x''=y''=z''=0 \qquad \text{and} \qquad x'=y'=z'=0 \tag{12.1.793}$$

We then get the following system:

$$\begin{aligned}&-\frac{GM_A}{\overline{AS}^3}(x+r_A)-\frac{GM_B}{\overline{BS}^3}(x-r_B)+\omega^2x=0\\&-\frac{GM_A}{\overline{AS}^3}y-\frac{GM_B}{\overline{BS}^3}y+\omega^2y=0\\&-\frac{GM_A}{\overline{AS}^3}z-\frac{GM_B}{\overline{BS}^3}z=0\end{aligned} \tag{12.1.794}$$

It is also immediately that the third equation has for only solution $z=0$ and thus ultimately the system reduces to:

$$\begin{aligned}&-\frac{GM_A}{\overline{AS}^3}(x+r_A)-\frac{GM_B}{\overline{BS}^3}(x-r_B)+\omega^2x=0\\&-\frac{GM_A}{\overline{AS}^3}y-\frac{GM_B}{\overline{BS}^3}y+\omega^2y=0\\&z=0\end{aligned} \tag{12.1.795}$$

The third equation simply means that the equilibrium positions are in the plane Oxy (we could suspect it a bit ...). The other two, we will see it later, lead us to consider five solutions that are our five Lagrangian points L1, ..., L5.

If we draw plot with an appropriate software the acceleration (respectively force) with the isoclines highlighted (curves on which the acceleration is equal) we get:

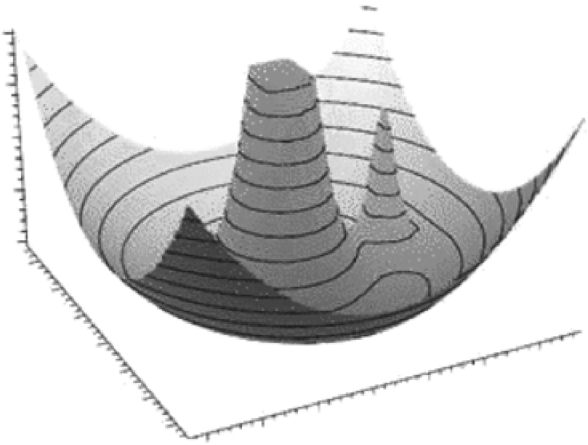


Figure 12.129: **Isoclines of the two-body system**

where we see that a short distance of the bodies the gravitational potential energy dominates, but that a large distances the centrifugal potential predominates and the shape of the surface is similar to that of a paraboloid.

By requesting the software to plot only the isoclines projected on a plane we get:

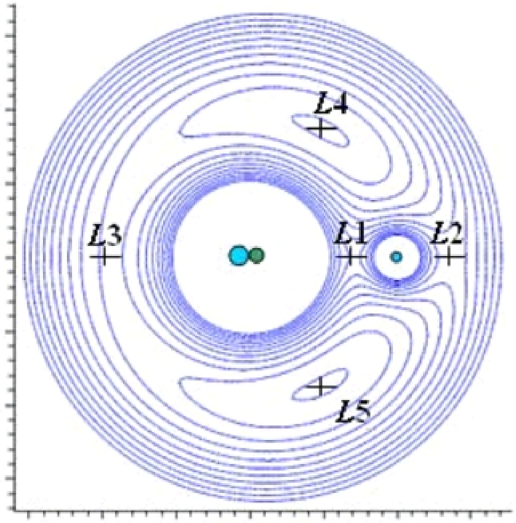

Figure 12.130: **Projected isoclines of the two body system on a plane**

where we have highlighted the five Lagrange points and where the stars (or celestial objects) are represented by blue dots and the centroid of the system by a green dot. It seems that isoclines are named in the astronomy field "Roche equipotentials lobes". Otherwise seen:

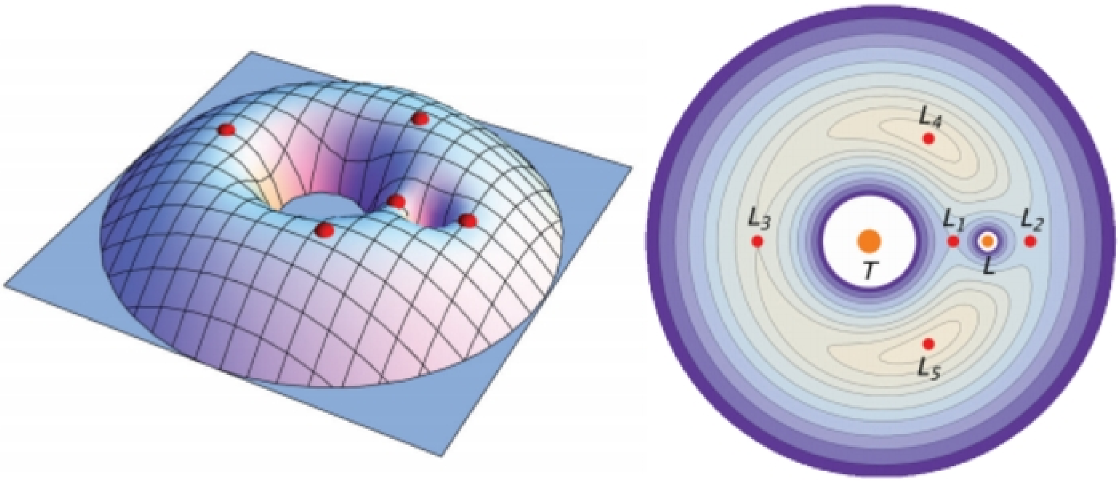

Figure 12.131: **Projected isoclines of the two body system on a plane**

For those wishing to reproduce these figures with MATLAB® here is how first proceed mathematically. From what we got previously, we have explicitly and in writing in a more academic form, the following relation:

$$\begin{aligned}
m\vec{a}_{R'} &= -(\vec{F}_A+\vec{F}_B)+m\omega^2 r\vec{e}_r-2m\vec{\omega}\times\vec{v}_r\\
&=-\left(-\frac{GM_Am}{\overline{AS}^3}\overrightarrow{AS}-\frac{GM_Bm}{\overline{BS}^3}\overrightarrow{BS}\right)+m\omega^2\vec{r}-2\begin{pmatrix}0\\0\\\omega_z\end{pmatrix}\times\begin{pmatrix}v_x\\v_y\\0\end{pmatrix}\\
&=\frac{GM_Am}{\overline{AS}^3}\overrightarrow{AS}+\frac{GM_Bm}{\overline{BS}^3}\overrightarrow{BS}+m\omega^2\vec{r}-2m\begin{pmatrix}-\omega_z v_y\\\omega_z v_x\\0\end{pmatrix}\\
&=\frac{GM_Am}{||\overrightarrow{AS}||^2}\frac{\overrightarrow{AS}}{||\overrightarrow{AS}||}+\frac{GM_Bm}{||\overrightarrow{BS}||^2}\frac{\overrightarrow{BS}}{||\overrightarrow{BS}||}+m\omega^2\vec{r}-2m\begin{pmatrix}-\omega_z v_y\\\omega_z v_x\\0\end{pmatrix}
\end{aligned}\tag{12.1.796}$$

As the point S is supposedly in equilibrium the last term vanishes (its speeds are zero in the rotating frame!). It then remains:

$$m\vec{a}_{R'}=\frac{GM_Am}{||\overrightarrow{AS}||^2}\frac{\overrightarrow{AS}}{||\overrightarrow{AS}||}+\frac{GM_Bm}{||\overrightarrow{BS}||^2}\frac{\overrightarrow{BS}}{||\overrightarrow{BS}||}+m\omega^2\vec{r}\tag{12.1.797}$$

We have proved for recall in the section of Classical Mechanics that:

$$\vec{F}=-\vec{\nabla}\cdot E_p\tag{12.1.798}$$

Then we have:

$$E_p=-\frac{GM_Am}{||\overrightarrow{AS}||}-\frac{GM_Bm}{||\overrightarrow{BS}||}-m\omega^2||\vec{r}||\tag{12.1.799}$$

Thus taken by unit mass of the satellite:

$$\boxed{E_{p,\text{eff}}=-\frac{GM_A}{||\overrightarrow{AS}||}-\frac{GM_B}{||\overrightarrow{BS}||}-\omega^2||\vec{r}||}\tag{12.1.800}$$

The application of these relations in MATLAB® 2013a then gives (sorry it's a bit long and its probably possible to do better ...):

```
%We build the grid plot that we will by anticipation densifiate where are the objects of interest
x1=linspace(-7E8,-8E5,150);
x2=linspace(8E5,1.2E8,150);
x3=linspace(1.6E8,7E8,150);
x=x1+x2+x3;
y=linspace(-7E8,7E8,450);
[X,Y]=meshgrid(x,y);
%These masses and G are real but the rest is fictitious so that the plot is readable
f=@(x,y) -(1.3346E20)./(sqrt((x-450).^2+y.^2))-(1.0038E19)./(sqrt((x-449999550).^2+y.^2))-(6.9E-7.*(x.^2+y.^2));
z=f(X,Y);
%We eliminate the values that are too big on Z to have an esthetical result to see
```

```
for i=1:450;
   for j=1:150;
      if (z(i,j)<-0.8E12) %to do with meshc a nice plot, limit to -8E11
         z(i,j)=-0.8E12;
      end;
   end;
end;
contour(X,Y,z,100); mesh(X,Y,z); meshc(X,Y,z);
az = 100; el = 25; view(az, el);
axis([-7E8 7E8 -0.8E9 0.8E9 -8E11 -4E11]);
colorbar; light; camlight('right');
```

That gives:

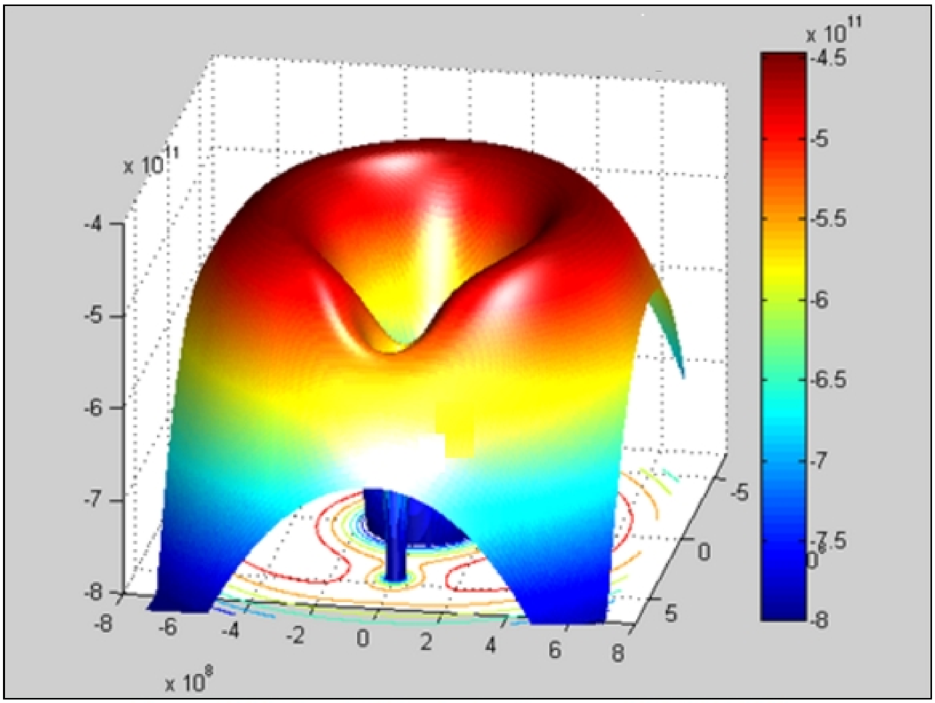

Figure 12.132: Lagrange plot and isoclines in 3D with MATLAB® 2013a

Or in 2D:

```
%  Author: David J. Muraki
%  15 jan 2004
%  coordinates

L = 15;   xr =  -L:0.05:L;   xi = xr;

[zr zi] = meshgrid(xr,xi);   zz = zr + i*zi;

%  first integral
GMs = 10.0;   Gme =  1.0;   R = 10;
As   = - R*Gme/(GMs+Gme);
ae   =   R*GMs/(GMs+Gme);
```

```
om2 = (GMs+Gme)/(R^3);

pot = om2*abs(zz).^2 + 2*GMs./abs(zz-As) + 2*Gme./abs(zz-ae);

force = om2*zz ...
      - GMs*(zz-As)./(abs(zz-As).^3) - Gme*(zz-ae)./(abs(zz-ae).^3)
         ;

%  contourplot
figure(1);  clf;  hold on
contour(xr,xi,pot,[3.2:0.05:4]);
axis([-1 1 -1 1]*L);
axis square;  colorbar
hold on
plot(As,0,’k*’);  plot(ae,0,’k*’)

ptitle = [’\bf potential energy & zero force contours’];
title(ptitle)
xlabel(’\bf Re(x)’)
ylabel(’\bf Im(x)’)

contour(xr,xi,real(force),[0 0],’k’);
contour(xr,xi,imag(force),[0 0],’k--’);
```

That gives:

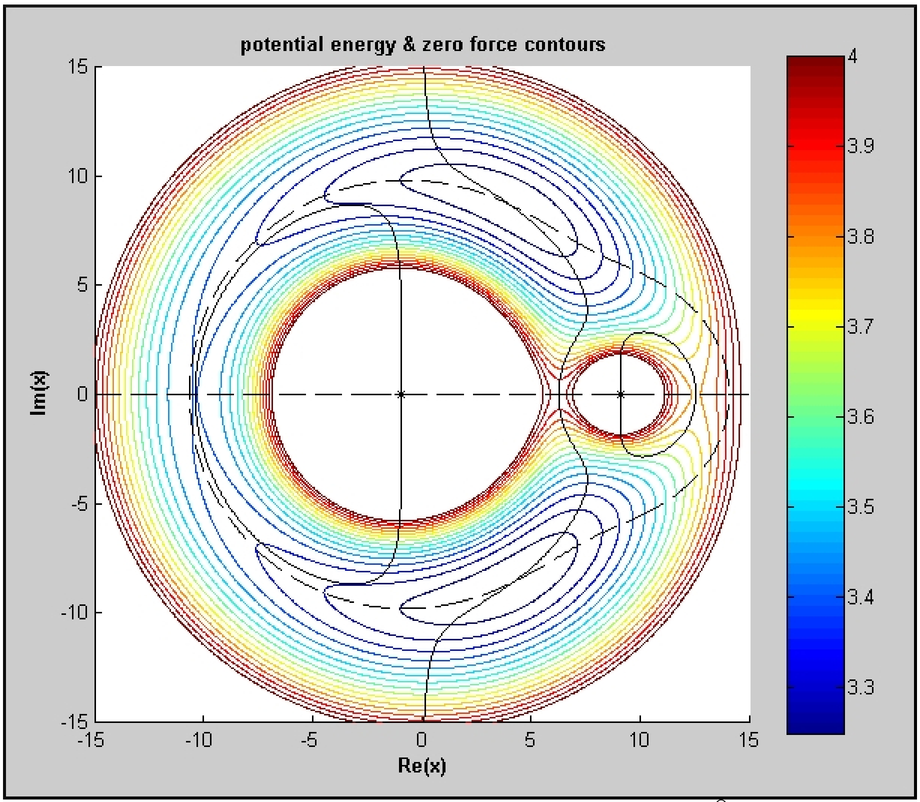

Figure 12.133: **Lagrange plot and isoclines in 2D with MATLAB® 2013a**

Some readers will notice that it is quite difficult to intuitively build such a potential configuration just by mind! In the rotating frame with the centroid of the two solid bodies, the potential resulting from the combination of rotational and gravitational potentials present three extrema L1, L2 and L3 on the right containing the both bodies. One of these maxima is between the two bodies as expected intuitively. The other two maxima are on the line connecting the two objects, but both on either side... which is more surprising. They come from the contribution to the potential of the rotating frame which can be difficult to model intuitively.

12.1.15.1 Equilibrium points of the first type

What we mean by equilibrium positions of the first type are simply solutions located on the line $\overline{AB}$ such that $y=0$ which is equivalent to study only:

$$-\frac{GM_A}{\overline{AS}^3}(x+r_A)-\frac{GM_B}{\overline{BS}^3}(x-r_B)+\omega^2 x=0 \tag{12.1.801}$$

with therefore:

$$\overline{AS}=|x+r_A| \quad \text{and} \quad \overline{BS}=|x-r_B| \tag{12.1.802}$$

To this situation, we will consider three possible corresponding sub-cases respectively L1, L2 and L3 as we will immediately see it.

12.1.15.1.1 L1 Lagrange point

In this first sub-case, we consider:

$$-r_A<x<r_B \tag{12.1.803}$$

What is also equivalent to have:

$$\begin{gathered}(x+r_A)>0\\(x-r_B)<0\end{gathered} \tag{12.1.804}$$

This allows us to write:

$$-\frac{GM_A}{\overline{AS}^3}(x+r_A)-\frac{GM_B}{\overline{BS}^3}(x-r_B)+\omega^2 x=0 \tag{12.1.805}$$

in the following simplified form:

$$-\frac{GM_A}{\overline{AS}^2}-\frac{GM_B}{\overline{BS}^2}+\omega^2 x=0 \tag{12.1.806}$$

Now to be able to say something about the possible solutions to this equation derive the left hand side. We then get:

$$\frac{2GM_A}{(x+r_A)^3}+\frac{2GM_B}{(r_B-x)^3}+\omega^2=0 \tag{12.1.807}$$

This term is strictly increasing from $-\infty$ to $+\infty$ when x describes $]-r_A, r_B[$. So there is a unique solution and equilibrium point denoted L1 (first Lagrange point) between A and B.

If we typically consider the Sun-Earth case where $M_A > M_B$ and therefore $r_A < r_B$ then on $x = 0$ we have:

$$-\frac{GM_A}{(0+r_A)^3}(0+r_A) - \frac{GM_B}{0-r_b}^3(0-r_B)+\omega^2 0 = -\frac{GM_A}{r_A^2} - \frac{GM_B}{r_B^2} \qquad (12.1.808)$$

what is immediately negative. The equilibrium position will be obtained for a positive value of x we will have to determine.

This value can be obtained by considering a limit case: when M_B tends to 0 (corresponding to a massive celestial object A turning around a mass B of a much much smaller celestial object), then A tends to O, r_A tends to 0 and therefore:

$$\omega^2 = \frac{GM_A}{R^3} \qquad (12.1.809)$$

with $R = \overline{AB}$. Therefore, in this limit case:

$$-\frac{GM_A}{\overline{AS}^2} + \frac{GM_B}{\overline{BS}^2} + \omega^2 x = 0 \qquad (12.1.810)$$

becomes in approximation:

$$-\frac{GM_A}{x^2} + \omega^2 x = 0 \qquad (12.1.811)$$

and therefore:

$$-\frac{GM_A}{x^2} + \left(\frac{GM_A}{R^3}\right) x = 0 \qquad (12.1.812)$$

So the only value of x satisfying this relation will be $x = R$.

In other words, the equilibrium point L1 we are looking after here is between A and B moves near B, that is near the less massive celestial object (which corresponds well to the first figure that we used to show the location of the five Lagrange points).

By this observation we can make the following calculations:

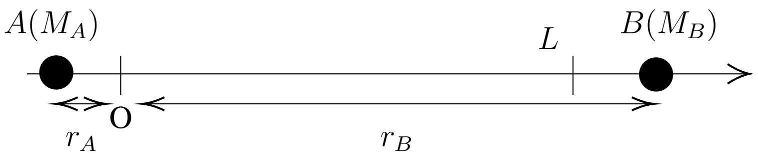

Figure 12.134: Configuration to mathematically determine the position of point L1

We have from the definition of center of gravity (see section Classical Mechanics page 3213):

$$\vec{r}_G = \frac{M_A\vec{r}_A + M_B\vec{r}_B}{M_A + M_B} \qquad (12.1.813)$$

As our study is done relatively to the centroid we have $\vec{r}_G=\vec{0}$ and therefore:

$$M_A\vec{r}_A+M_B\vec{r}_B=\vec{0} \tag{12.1.814}$$

From the above relation by taking the norm, we have obviously:

$$r_A=\frac{M_B}{M_A}r_B \tag{12.1.815}$$

The distance between the two celestial objects A and B remaining constant and being equal to $r=r_A+r_B$ we write:

$$\overline{AB}=r=r_A+r_B=\frac{M_B}{M_A}r_B+r_B=r_B\left(1+\frac{M_B}{M_A}\right)=\overline{\text{O}B}\left(1+\frac{M_B}{M_A}\right) \tag{12.1.816}$$

We deduce trivially two relations (the second being obtained by exactly the same reasoning as the first):

$$\overline{\text{O}B}=\frac{\overline{AB}}{1+\dfrac{M_B}{M_A}}\qquad\text{and}\qquad\overline{\text{O}A}=\frac{\overline{AB}}{1+\dfrac{M_A}{M_B}} \tag{12.1.817}$$

But since $M_A\gg M_B$ we can write roughly the first relation in the following approximate form (Taylor series):

$$\overline{\text{O}B}\cong\text{AB}\left(1-\frac{M_B}{M_A}\right) \tag{12.1.818}$$

and since:

$$r_A=\frac{M_B}{M_A}r_B\Leftrightarrow\overline{\text{O}A}=\frac{M_B}{M_A}\overline{\text{O}B} \tag{12.1.819}$$

we have also:

$$\overline{\text{O}A}=\frac{M_B}{M_A}\overline{\text{O}B}=\frac{M_B}{M_A}\frac{\overline{AB}}{1+\dfrac{M_B}{M_A}} \tag{12.1.820}$$

So with $M_A\gg M_B$:

$$\overline{\text{O}A}\cong\frac{M_B}{M_A}\overline{AB} \tag{12.1.821}$$

According to the limiting case studied previously, we can assume L at the neighbourhood of B such that it is possible to write:

$$\overline{\text{O}L}\cong\overline{\text{O}B}(1-\varepsilon) \tag{12.1.822}$$

with $\varepsilon\ll 1$.

Either using:

$$\overline{\text{O}B}\cong\overline{AB}\left(1-\frac{M_B}{M_A}\right) \tag{12.1.823}$$

Then we have:

$$\overline{\mathrm{O}L} \cong \overline{AB}(1-\varepsilon)\left(1-\frac{M_B}{M_A}\right)=\overline{AB}\left(1-\varepsilon-\frac{M_B}{M_A}\right) \tag{12.1.824}$$

by neglecting the infinitely small therm of order 2.

Hence:

$$\begin{aligned}\overline{LB}&=\overline{\mathrm{O}B}-\overline{\mathrm{O}L}=\overline{AB}\left(1-\frac{M_B}{M_A}\right)-\overline{AB}\left(1-\varepsilon-\frac{M_B}{M_A}\right)\\ \overline{LA}&=\overline{\mathrm{O}A}+\overline{\mathrm{O}L}=\frac{M_B}{M_A}\overline{AB}+\overline{AB}\left(1-\varepsilon-\frac{M_B}{M_A}\right)=\overline{AB}(1-\varepsilon)\end{aligned} \tag{12.1.825}$$

Now in the mentioned configuration the equilibrium is given by:

$$-\frac{GM_A}{\overline{LA}^2}+\frac{GM_B}{\overline{LB}^2}+\omega^2\overline{\mathrm{O}L}=0 \tag{12.1.826}$$

Therefore:

$$-\frac{GM_A}{\overline{AB}^2(1-\varepsilon)^2}+\frac{GM_B}{\varepsilon^2\overline{AB}^2}+\omega^2\overline{AB}\left(1-\varepsilon-\frac{M_B}{M_A}\right)=0 \tag{12.1.827}$$

Now the third Kepler's law gives us:

$$\frac{T^2}{\overline{AB}^3}=\frac{4\pi^2}{GM_A}\Rightarrow\frac{GM_A}{\overline{AB}^3}=\frac{4\pi^2}{T^2}=\left(\frac{2\pi}{T}\right)^2=\left(\frac{2\pi}{\frac{2\pi}{\omega}}\right)^2=\omega^2 \tag{12.1.828}$$

Therefore:

$$-\frac{GM_A}{\overline{AB}^2(1-\varepsilon)^2}+\frac{GM_B}{\varepsilon^2\overline{AB}^2}+G\frac{M_A}{\overline{AB}^3}\overline{AB}\left(1-\varepsilon-\frac{M_B}{M_A}\right)=0 \tag{12.1.829}$$

After simplification:

$$-\frac{M_A}{(1-\varepsilon)^2}+\frac{M_B}{\varepsilon^2}+M_A\left(1-\varepsilon-\frac{M_B}{M_A}\right)=0 \quad -\frac{M_A}{M_B}\frac{1}{(1-\varepsilon)^2}+\frac{1}{\varepsilon^2}+\frac{M_A}{M_B}\left(1-\varepsilon-\frac{M_B}{M_A}\right)=0 \tag{12.1.830}$$

Therefore:

$$\frac{1}{\varepsilon^2}-\frac{M_A}{M_B}(1+2\varepsilon)+\frac{M_A}{M_B}\left(1-\varepsilon-\frac{M_B}{M_A}\right)\cong 0 \tag{12.1.831}$$

Hence:

$$\frac{1}{\varepsilon^2}-3\frac{M_A}{M_B}\varepsilon-1\cong 0 \tag{12.1.832}$$

Since $1/\varepsilon^2$ is much greater than 1 and assuming that $3M_A/M_B$ then we have also:

$$\frac{1}{\varepsilon^2}\cong 3\frac{M_A}{M_B}\varepsilon \tag{12.1.833}$$

Thus finally:

$$\varepsilon \cong \sqrt[3]{\frac{M_B}{3M_A}} \tag{12.1.834}$$

and therefore:

$$\begin{aligned}\overline{LA}&=\overline{AB}(1-\varepsilon)=\overline{AB}\left(1-\sqrt[3]{\frac{M_B}{3M_A}}\right)=R\left(1-\sqrt[3]{\frac{M_B}{3M_A}}\right)\\ \overline{LB}&=\overline{AB}\varepsilon=R\sqrt[3]{\frac{M_B}{3M_A}}\end{aligned} \tag{12.1.835}$$

If we take the A for the Sun and B for the Earth, then:

$$\frac{M_B}{M_A}\cong 3\cdot 10^{-6} \qquad R\cong 150\cdot 10^6\ [\text{km}] \tag{12.1.836}$$

We find that the distance $\overline{LB}$ is then equal approximately to:

$$\overline{LB}=R\sqrt[3]{\frac{M_B}{3M_A}}\cong 1,500,000\ [\text{km}] \tag{12.1.837}$$

which is the L1 point where was placed the satellite SOHO (since the latter will thus never have its field of view obscured by the shadow of the Earth or the Moon).

A special case of the L1 point to consider is when $M_A=M_B=M$, then $r_A=r_B=r$, then O is the midpoint of $\overline{AB}$. Then we have:

$$\omega^2=\frac{GM}{R^3}=\frac{GM}{(2r)^3}=\frac{GM}{8r^3} \tag{12.1.838}$$

Therefore:

$$-\frac{GM_A}{\overline{AS}^2}+\frac{GM_B}{\overline{BS}^2}+\omega^2x=0 \tag{12.1.839}$$

becomes:

$$-\frac{GM}{(r+x)^2}+\frac{GM}{(x-r)^2}+\omega^2x=0\Rightarrow -\frac{1}{(r+x)^2}+\frac{1}{(x-r)^2}=-\frac{x}{8r^3} \tag{12.1.840}$$

Figure 12.135: **Non-composite image of the far side of the moon, illuminated by the Sun, as it crosses between the DISCOVR spacecraft's Earth Polychromatic Imaging Camera (EPIC) camera and telescope at Lagrange position L1, and the Earth (source: NASA)**

12.1.15.1.2 L2 Lagrange point

In this second sub-case, we consider:

$$x > r_B \tag{12.1.841}$$

Therefore we are looking for the equilibrium points beyond B.

Thus we have:

$$-\frac{GM_A}{AS^3}(x+r_A) - \frac{GM_B}{BS^3}(x-r_B) + \omega^2 x = 0 \tag{12.1.842}$$

which becomes simply:

$$-\frac{GM_A}{AS^2} - \frac{GM_B}{BS^2} + \omega^2 x = 0 \tag{12.1.843}$$

The left side is a strictly increasing function of x from $-\infty$ to $+\infty$ when x describes $[r_B, +\infty]$. So there is a unique solution, and an equilibrium point beyond B. This point is denoted: L2.

This value can be obtained by considering a limit case: when M_B tends to 0 (corresponding to a massive celestial object on A around which a much smaller mass object B turn around), then A tends to O, r_A to 0 and therefore:

$$\omega^2 = \frac{GM_A}{R^3} \tag{12.1.844}$$

with $R=\overline{AB}$. Therefore, in this limit case:

$$-\frac{GM_A}{\overline{AS}^3}-\frac{GM_B}{\overline{BS}^2}+\omega^2 x=0 \tag{12.1.845}$$

becomes approximately:

$$-\frac{GM_A}{x^2}+\omega^2 x=0 \tag{12.1.846}$$

and so:

$$-\frac{GM_A}{x^2}+\frac{GM_A}{R^3}x=0 \tag{12.1.847}$$

So the only value of x satisfying this relation will be $x=R$. The L2 point therefore ends up being merged with B.

Knowing this limit case, let us do a more detailed study. Consider the following diagram relatively to our previous limit case:

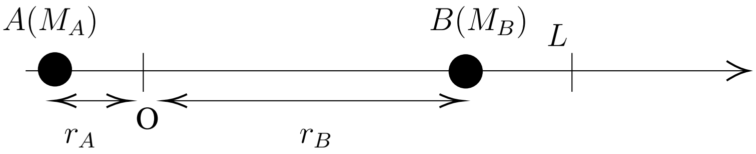

Figure 12.136: Configuration to mathematically determine the position of point L2

and let us consider $M_A \gg M_B$ without forgetting that in this scenario $x>r_B$.

We then have almost the same developments as for L1 but with the difference that:

$$\overline{\mathrm{O}L}\cong\overline{\mathrm{O}B}(1-\varepsilon) \tag{12.1.848}$$

becomes:

$$\overline{\mathrm{O}L}\cong\overline{\mathrm{O}B}(1+\varepsilon) \tag{12.1.849}$$

and that instead of having:

$$-\frac{GM_A}{\overline{LA}^2}+\frac{GM_B}{\overline{LB}^2}+\omega^2\overline{\mathrm{O}L}=0 \tag{12.1.850}$$

We have:

$$-\frac{GM_A}{\overline{LA}^2}-\frac{GM_B}{\overline{LB}^2}+\omega^2\overline{\mathrm{O}L}=0 \tag{12.1.851}$$

and therefore:

$$\overline{LA}=\overline{AB}(1+\varepsilon) \tag{12.1.852}$$

Still with:

$$\varepsilon=\sqrt[3]{\frac{M_B}{3M_A}} \tag{12.1.853}$$

and therefore:

$$\overline{LA}=\overline{AB}(1+\varepsilon)=\overline{AB}\left(1+\sqrt[3]{\frac{M_B}{3M_A}}\right)=R\left(1+\sqrt[3]{\frac{M_B}{3M_A}}\right) \tag{12.1.854}$$

which corresponds to the Lagrange point L2.

A special case again about L2 is when $M_A=M_B=M$, then $r_A=r_B=r$, then O is at the midpoint of $\overline{AB}$. Then we have:

$$\omega^2=\frac{GM}{R^3}=\frac{GM}{(2r)^3}=\frac{GM}{8r^3} \tag{12.1.855}$$

Therefore:

$$-\frac{GM_A}{\overline{AS}^2}-\frac{GM_B}{\overline{BS}^2}+\omega^2x=0 \tag{12.1.856}$$

becomes:

$$-\frac{GM}{(r+x)^2}-\frac{GM}{(x-r)^2}+\omega^2x=0\Rightarrow\frac{1}{(r+x)^2}+\frac{1}{(x-r)^2}=\frac{x}{8r^3} \tag{12.1.857}$$

It is no longer possible to extract the roots here (at least to my knowledge). It must be done through a numerical approximation. In Maple™ 4.00b, we simply put:

```
>solve(-1/(r+x)^2-1/(x-r)^2=x/(8*r^3),x);allvalues(");
```

and the only feasible solution in $\mathbb{R}$ is then $x\cong 2.8r$ and the others being in $\mathbb{C}$.

12.1.15.1.3 L3 Lagrange point

In this third sub-case, we consider:

$$x < -r_A \tag{12.1.858}$$

So we look for the equilibrium points beyond A.

Thus we have:

$$-\frac{GM_A}{\overline{AS}^3}(x+r_A)-\frac{GM_B}{\overline{BS}^3}(x-r_B)+\omega^2 x=0 \tag{12.1.859}$$

which becomes simply:

$$-\frac{GM_A}{\overline{AS}^2}-\frac{GM_B}{\overline{BS}^2}+\omega^2 x=0 \tag{12.1.860}$$

The left side is an increasing function of x from $-\infty$ to $+\infty$ when x describes $]-r_A,-\infty]$. So there is a unique solution, and one equilibrium point beyond A. This point is denoted: L3.

This value can be obtained by considering a limit case: when M_B tends to 0 (corresponding to a massive celestial object A turning around much smaller object B), then A tends to O, r_A to 0 and therefore:

$$\omega^2=\frac{GM_A}{R^3} \tag{12.1.861}$$

with $R=\overline{AB}$. Therefore, in this limit case:

$$-\frac{GM_A}{\overline{AS}^2}-\frac{GM_B}{\overline{BS}^2}+\omega^2 x=0 \tag{12.1.862}$$

becomes approximately:

$$-\frac{GM_A}{x^2}+\omega^2 x=0 \tag{12.1.863}$$

and therefore:

$$-\frac{GM_A}{x^2}+\frac{GM_A}{R^3}x=0 \tag{12.1.864}$$

So the only value of x satisfying this relation will be $x=R$. The point L3 will finish to merge with the position diametrically opposite to that of B.

Knowing this limit case, let us do a more detailed study now. Consider the following diagram relative to our previous limit situation:

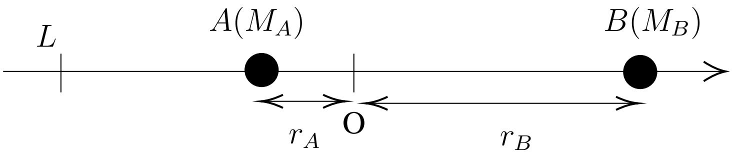

Figure 12.137: Configuration to mathematically determine the position of point L3

and let us still consider $M_A \gg M_B$ without forgetting that in this scenario $x < -r_A$.

We will first consider the following approximation:

$$\overline{AL} \cong \overline{AB}(1+\varepsilon) = R(1+\varepsilon) \tag{12.1.865}$$

and this one also (since $\overline{\mathrm{O}A}$ tends to zero as the celestial object A becomes very massive):

$$\overline{\mathrm{O}A} \cong \frac{M_B}{M_A}R \tag{12.1.866}$$

Since then:

$$\overline{\mathrm{O}L} = \overline{\mathrm{O}A} + \overline{AL} \cong R\left(1+\varepsilon+\frac{M_B}{M_A}\right) \tag{12.1.867}$$

We have also (...):

$$\omega^2 = \frac{GM_A}{R^3} \cong \frac{GM_A}{R^3}\left(1+\frac{M_B}{M_A}\right) \tag{12.1.868}$$

when at the limit where the celestial object A is really massive, we fall back on the first term ...

With the last two relations, we have:

$$\omega^2\overline{\mathrm{O}L} = R\left(1+\varepsilon+\frac{M_B}{M_A}\frac{GM_A}{R^3}\right)\left(1+\frac{M_B}{M_A}\right) \cong \frac{GM_A}{R^2}\left(1+\varepsilon+2\frac{M_B}{M_A}\right) \tag{12.1.869}$$

if we neglect the terms of the second order.

Furthermore, we have also:

$$\overline{BL} = \overline{AB} + \overline{AL} = R + R(1+\varepsilon) = 2R\left(1+\frac{\varepsilon}{2}\right) \tag{12.1.870}$$

Let us recall the equilibrium condition:

$$-\frac{GM_A}{\overline{AS}^2} - \frac{GM_B}{\overline{BS}^2} + \omega^2 x = -\frac{GM_A}{\overline{AL}^2} - \frac{GM_B}{\overline{BL}^2} + \omega^2\overline{\mathrm{O}L} = 0 \tag{12.1.871}$$

And let us put everything we got until now inside it:

$$-\frac{GM_A}{(R(1+\varepsilon))^2} - \frac{GM_B}{\left(2R\left(1+\frac{\varepsilon}{2}\right)\right)^2} + \frac{GM_A}{R^2}\left(1+\varepsilon+2\frac{M_B}{M_A}\right) = 0 \tag{12.1.872}$$

What becomes after simplifications:

$$\frac{M_A}{M_B}\frac{1}{(1+\varepsilon)^2} + \frac{1}{4\left(1+\frac{\varepsilon}{2}\right)^2} = \frac{M_A}{M_B}\left(1+\varepsilon+2\frac{M_B}{M_A}\right) \tag{12.1.873}$$

after a small approximation:

$$4\frac{M_A}{M_B}(1-2\varepsilon) + (1-\varepsilon) = 4\frac{M_A}{M_B}\left(1+\varepsilon+2\frac{M_B}{M_A}\right) \tag{12.1.874}$$

after simplification:

$$-12\varepsilon\frac{M_A}{M_B}=7 \tag{12.1.875}$$

Hence:

$$\varepsilon=-\frac{7}{12}\frac{M_B}{M_A} \tag{12.1.876}$$

and finally:

$$\overline{OB}\cong R\left(1+\varepsilon+\frac{M_B}{M_A}\right)\cong R\left(1-\frac{7}{12}\frac{M_B}{M_A}+\frac{M_B}{M_A}\right)=R\left(1+\frac{5}{12}\frac{M_B}{M_A}\right) \tag{12.1.877}$$

Remark

For some Si-Fi authors, for reminder... this L3 point opposite to the Earth relatively to the Sun (actually a G2V-type star, aka yellow dwarf) would hide us a hypothetical planet that would be forever hidden to us by the Sun..........

12.1.15.2 Equilibrium points of the second type

The equilibrium positions of the second type are those for which $y\neq 0$. In other words the points outside of the line $\overline{AB}$, but still in the plane Oxy.

Thus, our system of equations remains:

$$\begin{aligned}&-\frac{GM_A}{\overline{AS}^3}(x+r_A)-\frac{GM_B}{\overline{BS}^3}(x-r_A)+\omega^2x=0\\&-\frac{GM_A}{\overline{AS}^3}y-\frac{GM_B}{\overline{BS}^3}y+\omega^2y=0\\&Z=0\end{aligned} \tag{12.1.878}$$

12.1.15.2.1 L4, L5 Lagrange points

To determine the remaining equilibrium points, we can divide the second equation of the system such that the latter becomes:

$$\begin{aligned}&-\frac{GM_A}{\overline{AS}^3}(x+r_A)-\frac{GM_B}{\overline{BS}^3}(x-r_A)+\omega^2x=0\\&-\frac{GM_A}{\overline{AS}^3}-\frac{GM_B}{\overline{BS}^3}+\omega^2=0\end{aligned} \tag{12.1.879}$$

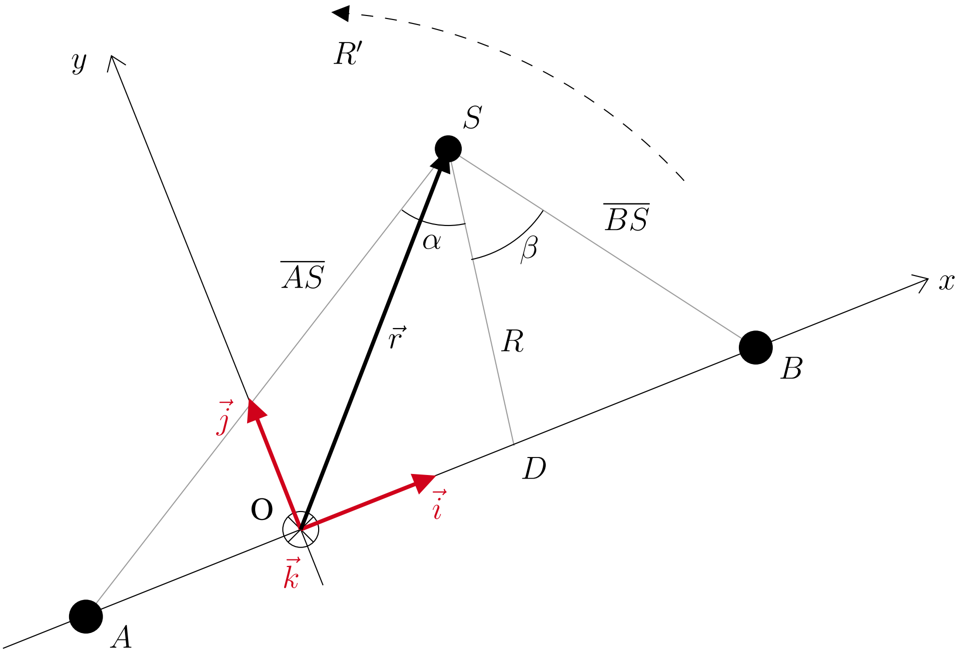

Figure 12.138: **Configuration to mathematically determine the position of points L4,L5**

where $\overline{AB}$ is obviously the distance between A and B and D is the centroid of the system given by (see section Classical Mechanics page 3213):

$$\overline{AD}=\overline{AB}\frac{M_B}{M_A+M_B} \qquad \text{or} \qquad \overline{DB}=\overline{AB}\frac{M_A}{M_A+M_B} \tag{12.1.880}$$

which are the radii of gyration of the bodies A and B.

It is easy to verify that the sum of both previous distances is equal to $\overline{AB}$ and their proportion M_B/M_A. Another form of $\overline{DB}$ (which will be useful) is obtained by dividing the numerator and denominator by M_A:

$$\overline{DB}=\frac{\overline{AB}}{1+\dfrac{M_B}{M_A}} \tag{12.1.881}$$

We know according to our previous calculations that $\overline{AS}=\overline{BS}$ but this is insufficient. We still want to know the angles of the vertices A, B, S, and this is what we will look for now.

In this context, if a satellite S is in equilibrium, there will always remain at the same distance of A or B. The center of rotation of the 3 points is the point D, the mass A itself revolves around it. If the satellite, S, remains stable, the three bodies have the same orbital period T. If S is immobile in this frame in rotation it will not be subject to the Coriolis force but only to centrifugal (fictional) force of A and of B.

Let us denote by v_B the rotation speed of B and v_S the rotation speed of S. Then we have:

$$2\pi R=v_S T \tag{12.1.882}$$

and:

$$2\pi\frac{\overline{AB}}{1+\dfrac{M_B}{M_A}}=v_B T \tag{12.1.883}$$

From whose we get that:

$$\frac{2\pi}{T}=\frac{v_S}{R} \tag{12.1.884}$$

and:

$$\frac{2\pi}{T}=\frac{v_B}{\overline{AB}}\left(1+\frac{M_B}{M_A}\right) \tag{12.1.885}$$

So we can equate these two expressions:

$$\frac{v_S}{R}=\frac{v_B}{\overline{AB}}\left(1+\frac{M_B}{M_A}\right) \tag{12.1.886}$$

This merely expresses the well known fact that if two objects rotate together, the furthest one from the centroid is the fastest. Speeds are proportional to the distances from the centroid.

The centrifugal (fictional) force on B is in equilibrium with the gravitational force of A and it is expressed by:

$$M_B\frac{v_B^2}{\left(\dfrac{\overline{AB}}{1+\dfrac{M_B}{M_A}}\right)}=\frac{M_B}{\overline{AB}}v_B^2\left(1+\frac{M_B}{M_A}\right)=G\frac{M_AM_B}{\overline{AB}^2} \tag{12.1.887}$$

Thus by simplifying:

$$G\frac{M_A}{\overline{AB}}=v_B^2\left(1+\frac{M_B}{M_A}\right) \tag{12.1.888}$$

Similarly, the centrifugal (fictional) force applied on S is:

$$M_S\frac{v_S^2}{R} \tag{12.1.889}$$

It is balanced by the forces of attraction $\vec{F}_A$,$\vec{F}_B$ of the objects A and B. However, only the components of these forces located on the line R oppose efficiently to this centrifugal (fictional) force. Hence:

$$M_S\frac{v_S^2}{R}=F_A\cos(\alpha)+F_B\cos(\beta) \tag{12.1.890}$$

$$M_S\frac{v_S^2}{R}=F_A\cos(\alpha)+F_B\cos(\beta) \tag{12.1.891}$$

and as:

$$F_A=\frac{GM_AM_S}{\overline{AS}^2} \quad \text{and} \quad F_B=\frac{GM_BM_S}{\overline{BS}^2} \tag{12.1.892}$$

We then have:

$$\frac{v_S^2}{R}=\frac{GM_A}{\overline{AS}^2}\cos(\alpha)+\frac{GM_B}{\overline{BS}^2}\cos(\beta) \tag{12.1.893}$$

In addition, the forces applied to S and perpendicular to R must vanish. If not, the object S would follow the largest mass and would not remain in position and would therefore no longer be in equilibrium. We must then have:

$$F_A \sin(\alpha) = F_B \sin(\beta) \tag{12.1.894}$$

Or, after substitution and simplification:

$$F_A \sin(\alpha) = F_B \sin(\beta) \tag{12.1.895}$$

Of all the equations obtained up to now the only that bother us are those containing both speeds and angles α,β. This requires that we must arrive to eliminate what is convenient to have only the last two parameters (that is to say: the angles).

For this, we take the square:

$$\frac{v_S^2}{R^2} = \frac{v_B^2}{\overline{AB}^2}\left(1+\frac{M_B}{M_A}\right)^2 \tag{12.1.896}$$

We multiply both sides by $\overline{AB}^2$ and we divide by $1+\dfrac{M_B}{M_A}$:

$$\frac{v_S^2\overline{AB}^2}{R^2\left(1+\dfrac{M_B}{M_A}\right)} = v_B^2\left(1+\frac{M_B}{M_A}\right) \tag{12.1.897}$$

which is similar to:

$$G\frac{M_A}{\overline{AB}} = v_B^2\left(1+\frac{M_B}{M_A}\right) \tag{12.1.898}$$

Thus equating:

$$\frac{v_S^2\overline{AB}^2}{R^2\left(1+\dfrac{M_B}{M_A}\right)} = G\frac{M_A}{\overline{AB}} \tag{12.1.899}$$

So we removed the speed of B. Now, let us multiply both sides by $\left(1+\dfrac{M_B}{M_A}\right)R$ and divide by $\overline{AB}^2$:

$$\frac{v_S^2}{R} = \frac{GM_A}{\overline{AB}^3}R\left(1+\frac{M_B}{M_A}\right) \tag{12.1.900}$$

which is similar to:

$$\frac{v_S^2}{R} = \frac{GM_A}{\overline{AS}^2}\cos(\alpha) + \frac{GM_B}{\overline{BS}^2}\cos(\beta) \tag{12.1.901}$$

Therefore:

$$\frac{GM_A}{\overline{AB}^2}\frac{R}{\overline{AB}}\left(1+\frac{M_B}{M_A}\right) = \frac{GM_A}{\overline{AS}^2}\cos(\alpha) + \frac{GM_B}{\overline{BS}^2}\cos(\beta) \tag{12.1.902}$$

By dividing the whole by GM_A we find:

$$\frac{1}{\overline{AB}^2}\frac{R}{\overline{AB}}\left(1+\frac{M_A}{M_B}\right)=\frac{1}{\overline{AS}^2}=\frac{1}{\overline{AS}^2}\cos(\alpha)+\frac{M_B}{M_A}\frac{1}{\overline{BS}^2}\cos(\beta) \tag{12.1.903}$$

And as we have proved at the beginning $\overline{AS}=\overline{BS}$ that we will denote by R', then we have:

$$\frac{R'^2}{\overline{AB}^2}\frac{R}{\overline{AB}\left(1+\dfrac{M_B}{M_A}\right)}=\cos(\alpha)+\frac{M_B}{M_A}\cos(\beta) \tag{12.1.904}$$

and let us recall that we have:

$$\frac{M_A}{\overline{AS}^2}\sin(\alpha)=\frac{M_B}{\overline{BS}^2}\sin(\beta) \tag{12.1.905}$$

Therefore:

$$\frac{M_B}{M_A}=\frac{\sin(\alpha)}{\sin(\beta)} \tag{12.1.906}$$

This allows us to write:

$$\frac{R'^2}{\overline{AB}^2}\frac{R}{\overline{AB}}\left(1+\frac{M_B}{M_A}\right)=\cos(\alpha)+\frac{\sin(\alpha)}{\sin(\beta)}\cos(\beta) \tag{12.1.907}$$

And multiplying by $\sin(\beta)$:

$$\frac{R'^2}{\overline{AB}^2}\sin(\beta)\frac{R}{\overline{AB}}\left(1+\frac{M_B}{M_A}\right)=\sin(\beta)\cos(\alpha)+\sin(\alpha)\cos(\beta)=\sin(\alpha+\beta) \tag{12.1.908}$$

We can now notice a thing (not easy to see...). If $R'=\overline{AB}$ (that is that the triangle ABS is equilateral) the previous relations simplifies to:

$$\sin(\beta)\frac{1}{\overline{AB}}\left(1+\frac{M_B}{M_A}\right)=\frac{\sin(\hat{S})}{R} \tag{12.1.909}$$

But, if the triangle is really equilateral, then we have (see section Geometric Shapes page 2902):

$$\sin(\hat{S})=\sin(\hat{A})=\sin(\hat{\beta}) \tag{12.1.910}$$

Hence:

$$\frac{\sin(\beta)}{\overline{AB}\dfrac{M_A}{M_A+M_B}}=\frac{\sin(\hat{\beta})}{R} \tag{12.1.911}$$

What can finally write:

$$\frac{\sin(\beta)}{\overline{DB}}=\frac{\sin(\hat{\beta})}{R} \tag{12.1.912}$$

Which is just the sine theorem for the triangle SDB (see section Trigonometry page 2528) and is therefore certain. Returning back, we can now prove that all previous equations are satisfied if and only if ABS is equilateral. If we had not put ABS as equilateral, we would have gotten a different relation of the sine theorem, without possible verification, and the set of equations required for equilibrium at the point S could not be met.

Conclusion of the thing ... the system gives as a solution:

$$\overline{AS}=\overline{BS}=R \tag{12.1.913}$$

ABS (or ABL regardless the notation), then forms an equilateral triangle. The two equilibrium points are denoted L4 and L5. L4 is located in advance with respect to the less massive celestial object and L5 is late relatively to it.

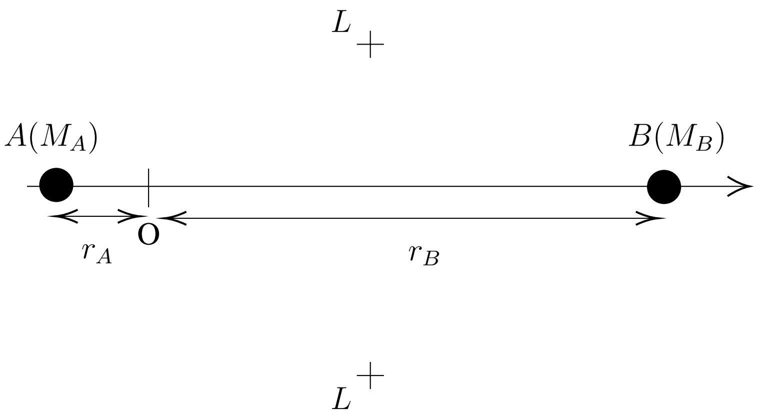

Figure 12.139: **L4 and L5 equilateral triangle**

In the year 12000 (holocene calendar), 385 asteroids in the L4 point and 188 asteroids in the L5 point were counted on the orbit of Jupiter, but located precisely in an equilateral triangle with the Sun (actually a G2V-type star, aka yellow dwarf) and either side of Jupiter: these are the Trojan planets. It was also observed two objects at the point L5 of Mars discovered in 11990 and 11998 (holocene calendar).

For people reading this textbook on a computer with Adobe Flash player installed and activated, here is an animation that shows a few others "stable" (because on the very long term almost nothing is really stable!) three bodies planar periodic orbits made with Python™ (otherwise see here: `https://vimeo.com/1059418615`):

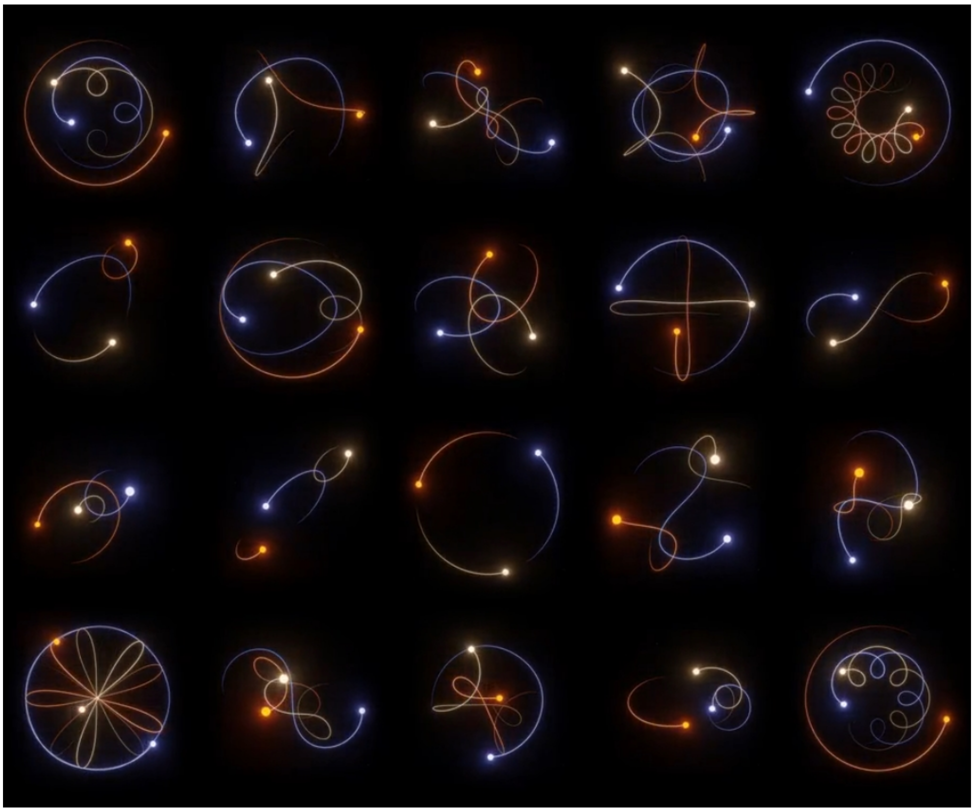

Figure 12.140: **Animation of few three bodies planar periodic orbits made with Python™**

The reader can visit Ricky Reusser Python™ notebook at https://observablehq.com/@rreusser/periodic-planar-three-body-orbits to recreate 2703 periodic solutions of the planar three-body problem.

12.1.15.3 Hill sphere (sphere of influence)

The "Hill sphere", or "sphere of influence" (S.O.I.), is a common model for the calculation of a gravitational sphere of influence. It is the most commonly used model to calculate the spatial extent of gravitational influence of an astronomical body (m) in which it dominates over the gravitational influence of other bodies, particularly a primary (M).[It is sometimes confused with other models of gravitational influence, such as the Laplace sphere or being named the Roche sphere, the latter causing confusion with the Roche limit. It was defined by the American astronomer George William Hill, based on the work of the French astronomer Édouard Roche.

To be retained by a more gravitationally attracting astrophysical object - a planet by a more massive star, a moon by a more massive planet - the less massive body must have an orbit that lies within the gravitational potential represented by the more massive body's Hill sphere. That moon would, in turn, have a Hill sphere of its own, and any object within that distance would tend to become a satellite of the moon, rather than of the planet itself.

One simple view of the extent of the Solar System is that it is bounded by the Hill sphere of the Sun (engendered by the Sun's interaction with the galactic nucleus or other more massive stars). A more complex example is the one at right, the Earth's Hill sphere, which extends between the Lagrange points L1 and L2, which lie along the line of centers of the Earth and the more massive Sun. The gravitational influence of the less massive body is least in that direction, and so it acts as the limiting factor for the size of the Hill sphere; beyond that distance, a third object in orbit around the Earth would spend at least part of its orbit outside the Hill sphere, and would be progressively perturbed by the tidal forces of the more massive body, the Sun, eventually ending up orbiting the latter.

For the derivation let us consider the following three body system with circular orbits:

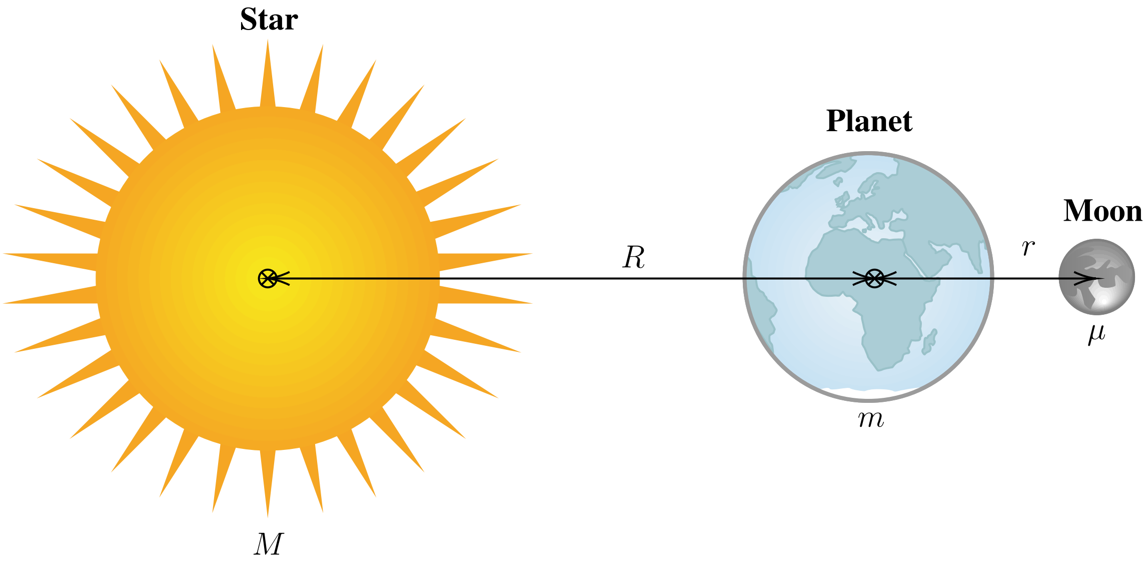

Figure 12.141: **Determining the Hill sphere radius**

The satellite or moon (mass μ) is orbiting the star (mass M) with the same angular velocity ω at the distance $R+r$ as the planet (mass m) at the distance R (permanent full moon position).

The equilibrium condition for the planet is obviously:

$$m\omega^2 R = G\frac{mM}{R^2} \tag{12.1.914}$$

Hence:

$$\omega^2 = \frac{GM}{R^3} \tag{12.1.915}$$

The satellite is dragged by the combined gravitational forces exerted by the star and the planet:

$$\mu\omega^2(R+r) = G\frac{\mu M}{(R+r)^2} + G\frac{\mu m}{r^2} \tag{12.1.916}$$

Inserting ω^2:

$$G\mu\frac{R+r}{R^3} = G\frac{\mu M}{(R+r)^2} + G\frac{\mu m}{r^2} \tag{12.1.917}$$

Simplifying by μ, we get:

$$G\frac{R+r}{R^3} = G\frac{M}{(R+r)^2} + G\frac{m}{r^2} \tag{12.1.918}$$

Multiplying both sides by $(R+r)^2R^3$, we get:

$$M(R+r)^3r^2 = MR^3r^2 + mR^3(R+r)^2 \qquad (12.1.919)$$

Rearranging and developing, we get:

$$mR^3(R+r)^2 = Mr^2(R^3+3R^2r+3Rr^2+r^3) - MR^3r^2 \qquad (12.1.920)$$

Factoring:

$$mR^3(R+r)^2 = Mr^3(3R^2+3Rr+r^2) \qquad (12.1.921)$$

For $r \ll R$ we have:$(R+r)^2 \cong R^2$, and $3Rr+r^2 \cong 0$. The relation simplifies:

$$mR^5 \cong 3Mr^3R^2 \qquad (12.1.922)$$

After trivial simplification:

$$mR^3 \cong 3Mr^3 \qquad (12.1.923)$$

So finally:

$$\boxed{r_{\text{Hill}} \cong R\sqrt[3]{\frac{m}{3M}}} \qquad (12.1.924)$$

For the triplet Sun, Earth, Moon, we get for example:

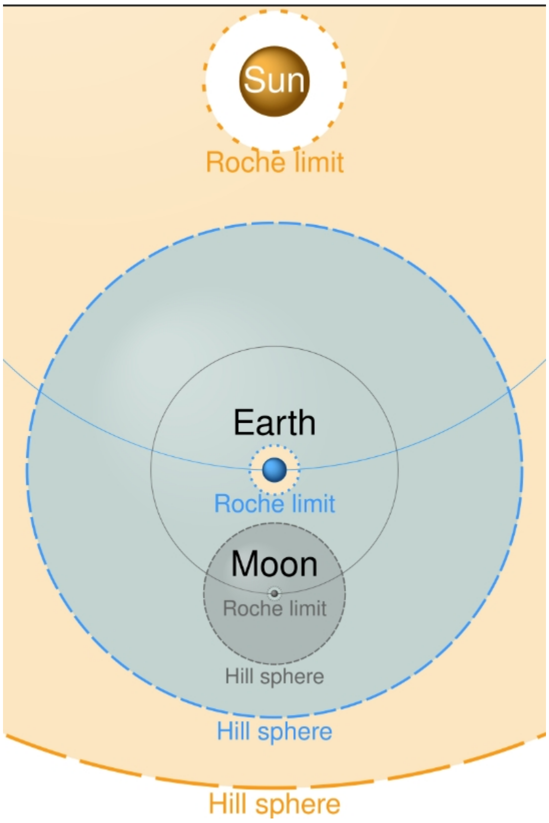
$$r_{\text{Hill}} \cong R\sqrt[3]{\frac{m_{\text{Earth}}}{3M_{\text{Sun}}}} \cong 149,600,000\sqrt[3]{\frac{5.97\cdot 10^{24}}{3(1.99\cdot 10^{33})}} \cong 1,496,000\;[\text{km}] \qquad (12.1.925)$$

So for this special case we have therefore:

$$r_{\text{Moon}} \cong \frac{1}{4}r_{\text{Hill}} \qquad (12.1.926)$$

This answer the famous question of many people of why the Moon is not falling down to the Sun even if the force of the Sun on the Moon is greater than the force of the Earth on the Moon!

Below a schematic, not-to-scale representation of Hill spheres (as 2D radii) and Roche limits of each body of the Sun-Earth-Moon system. The actual Hill radius for the Earth-Moon pair is on the order of $60,000$ [km] (i.e., extending less than one-sixth the distance of the $378,000$ [km] between the Moon and the Earth):



Sun
Roche limit
Earth
Roche limit
Moon
Roche limit
Hill sphere
Hill sphere
Hill sphere

The Hill sphere is only an approximation, and other forces (such as radiation pressure or the Yarkovsky effect) can eventually perturb an object out of the sphere. As stated, the satellite (third mass) should be small enough that its gravity contributes negligibly.

12.1.16 Relativistic Doppler-Fizeau Effect

The Doppler effect is the difference between the frequency of the transmitted wave and the received wave when the transmitter and receiver are moving relative to each other (see section Music Mathematics page 8212). This is an effect that must be take into account astronomy to calculate the distance of the body assuming its known (or estimated) emission wavelength and measuring its received wavelength or for measuring the speed of rotation (radial velocity) of stars by observing very precisely and successively their opposite edges and measuring the shift of the spectrum obtained.

In the early 121st century (holocene calendar) the precision and finesse of the spectra of measures has reached a level that allows to observe even minimal changes in the distance of stars and so speculate on possible planetary satellites (this may work if the plane of the orbit passes through the Earth):

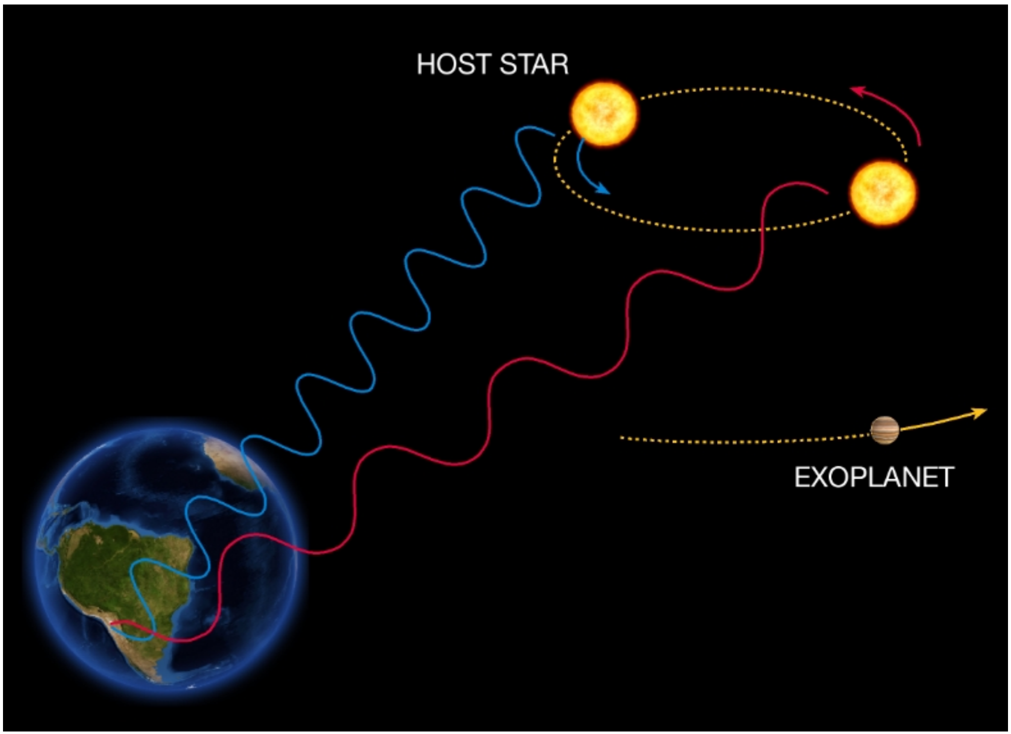


Figure 12.142: Doppler-Effect radial velocity method (source: ESO Press Photo 22e/05 12007-04-11)

The Doppler effect of electromagnetic waves must be discussed independently of the acoustic Doppler effect (also named "Galilean Doppler effect") studied in the section of Music Mathematics (see page 8212). First, because the electromagnetic waves do not consist of a material movement and therefore the speed of the source relative to the medium does not enter into the discussion, then because their velocity is c (the speed of light) and remains the same for all observers independently of their relative movements. The Doppler effect for electromagnetic waves is thus calculated necessarily using the principle of relativity and is symmetrical with respect to relative movement of the source and the observer (as opposed to acoustic cases).

For an observer in an inertial reference frame, a plane and harmonic electromagnetic wave can be described by a function of the form:

$$\sin(kx-\omega t) \tag{12.1.927}$$

multiplied by an appropriate amplitude factor. For an observer attached to another inertial frame, the components x and t should be replaced with x' and t', obtained by the Lorentz transformation (see section Special Relativity page 5633), and that latter will therefore write to describing plane wave:

$$\sin(k'x'-\omega't') \tag{12.1.928}$$

where k' and ω' are not necessarily the same as that of the another observer (precisely this is what we want to determine). Moreover, the principle of relativity has allowed us to demonstrate in the section of Special Relativity that:

$$\frac{\partial}{\partial t^2}-c^2\frac{\partial^2}{\partial x^2}=\frac{\partial}{\partial t'^2}-c^2\frac{\partial^2}{\partial x'^2} \tag{12.1.929}$$

This assumes that the expression:

$$kx-\omega t \tag{12.1.930}$$

remains invariant when we move from one inertial observer to the other. We then have:

$$kx-\omega t=k'x'-\omega't' \tag{12.1.931}$$

Using the Lorentz transformation relations (see section Special Relativity page 5633), we have immediately:

$$k\frac{x'+vt'}{\sqrt{1-\dfrac{v^2}{c^2}}}-\omega\frac{t'+v\dfrac{x'}{c^2}}{\sqrt{1-\dfrac{v^2}{c^2}}}=k'x'-\omega't' \tag{12.1.932}$$

Hence:

$$\frac{kx'+kvt'-\omega t'-\omega v\dfrac{x'}{c^2}}{\sqrt{1-\dfrac{v^2}{c^2}}}=k'x'-\omega't' \tag{12.1.933}$$

Grouping we get:

$$\frac{\left(k-\omega\dfrac{v}{c^2}\right)x'-(\omega-kv)\,t'}{\sqrt{1-\dfrac{v^2}{c^2}}}=k'x'-\omega't' \tag{12.1.934}$$

By identification, it comes immediately:

$$k'=\frac{k-\omega\dfrac{v}{c^2}}{\sqrt{1-\dfrac{v^2}{c^2}}}\qquad \omega'=\frac{\omega-kv}{\sqrt{1-\dfrac{v^2}{c^2}}} \tag{12.1.935}$$

If we consider that:

$$\omega=ck \tag{12.1.936}$$

in the case of electromagnetic waves, we can write each of these relation in the form:

$$\boxed{k'=k\frac{1-\dfrac{v}{c}}{\sqrt{1-\dfrac{v^2}{c^2}}}\qquad \omega'=\omega\frac{1-\dfrac{v}{c}}{\sqrt{1-\dfrac{v^2}{c^2}}}} \tag{12.1.937}$$

The ratio visible in the both expression above is named the "radial relativistic doppler redshift" and is denoted by:

$$\frac{1-\dfrac{v}{c}}{\sqrt{1-\dfrac{v^2}{c^2}}}=\left(1-\frac{v}{c}\right)\gamma \tag{12.1.938}$$

for a movement of the observer relative to the source in the direction of propagation (the range of this function is bounded to $[0,1]$). In the other case (opposite direction) we have obviously:

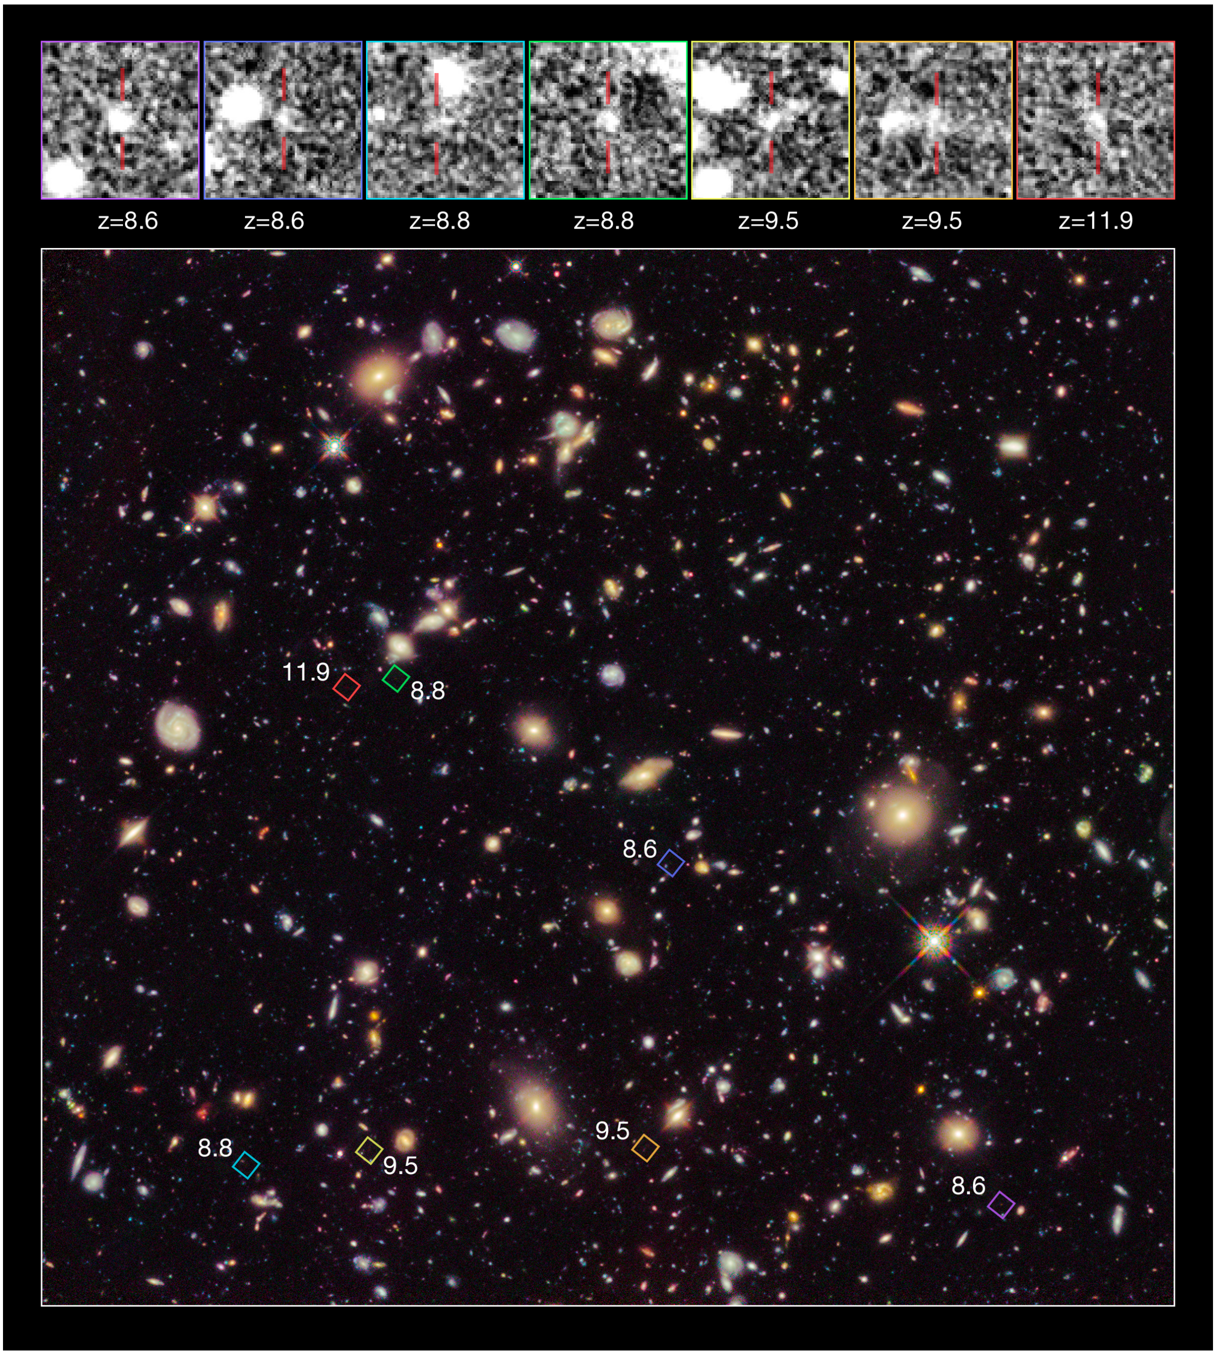
$$\frac{1+\dfrac{v}{c}}{\sqrt{1-\dfrac{v^2}{c^2}}}=\left(1+\frac{v}{c}\right)\gamma \tag{12.1.939}$$

That is unbounded and has for range $[1,+\infty[$. Physicists like to normalized stuffs so that the range is $[0,+\infty[$, so we write and define the "relativistic doppler redshift" for opposite direction as:

$$z=\frac{1+\dfrac{v}{c}}{\sqrt{1-\dfrac{v^2}{c^2}}}-=\left(1+\frac{v}{c}\right)\gamma-1 \tag{12.1.940}$$

Or more commonly written as:

$$\boxed{1+z=\frac{1+\dfrac{v}{c}}{\sqrt{1-\dfrac{v^2}{c^2}}}=\gamma\left(1+\frac{v}{c}\right)} \tag{12.1.941}$$



z=8.6
z=8.6
z=8.8

Figure 12.143: **High-redshift galaxy candidates in the Hubble ultra deep field 12012 (source: NASA, ESA, R. Ellis (Caltech), and the HUDF Team)**

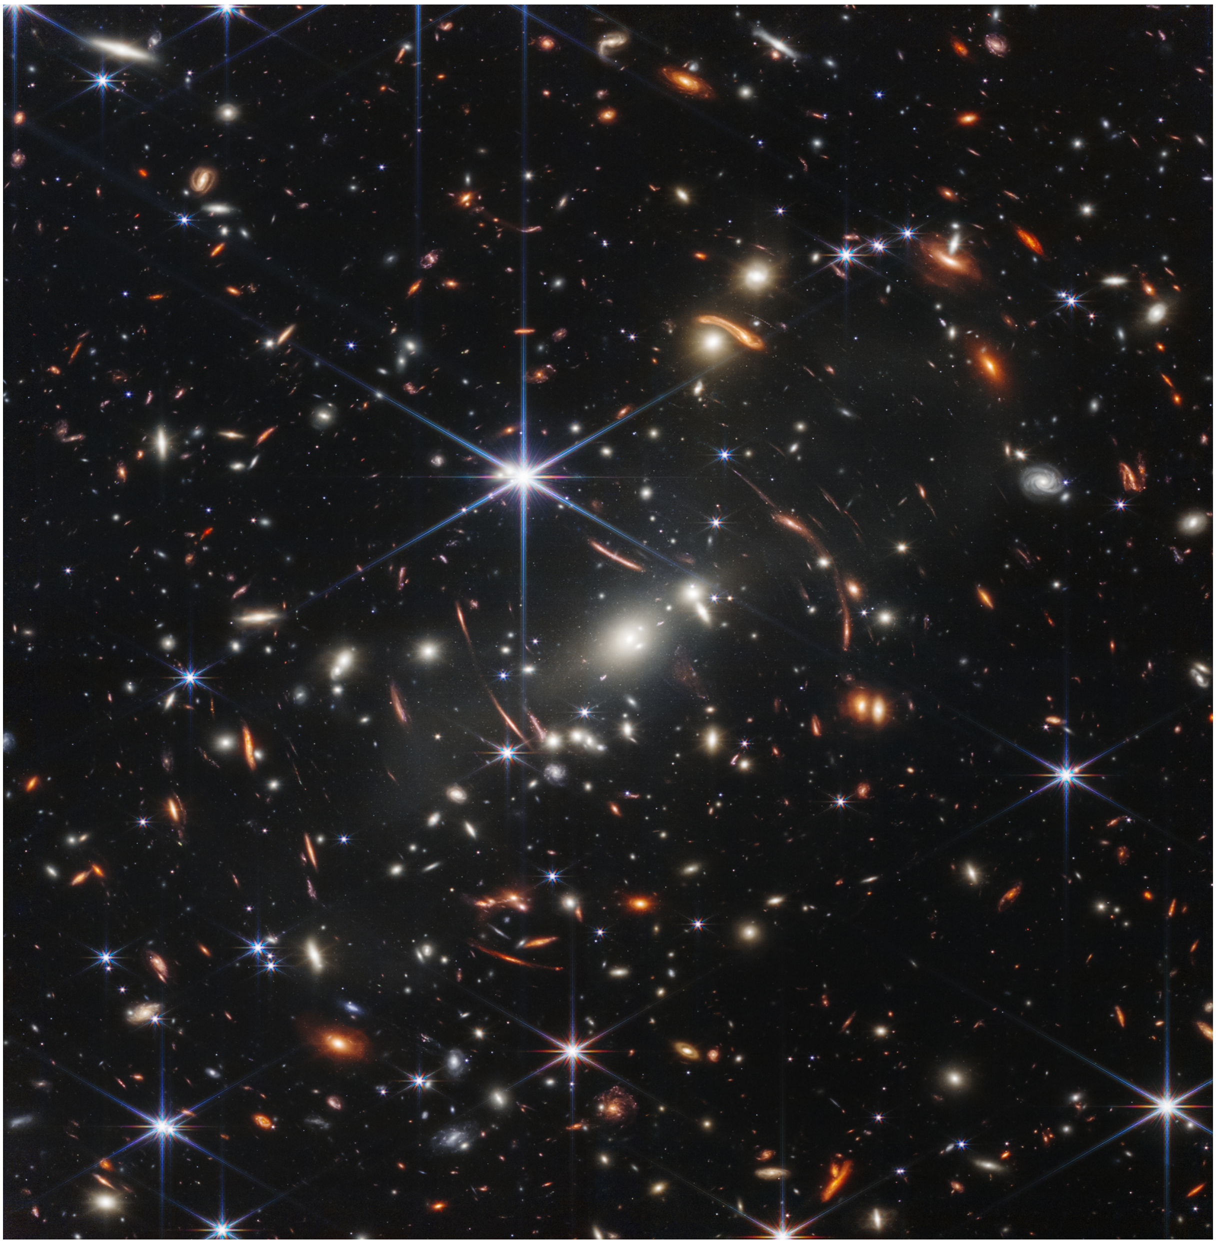

Figure 12.144: **James Webb Telescope galaxy cluster SMACS 0723 deep field released in 12022, July 11 (source: NASA)**

Obviously if the source or observer don't move away but approach then we not have a red shift but a "blueshift".

Furthermore, the last relation with the pulsations is most often written in the literature as follows:

$$2\pi f = 2\pi f' \frac{1+\dfrac{v}{c}}{\sqrt{1-\dfrac{v^2}{c^2}}} = 2\pi f' \frac{1+\dfrac{v}{c}}{\sqrt{\left(1-\dfrac{v}{c}\right)\left(1+\dfrac{v}{c}\right)}} = 2\pi f' \frac{\sqrt{1+\dfrac{v}{c}}}{\sqrt{1-\dfrac{v}{c}}} \qquad (12.1.942)$$

Which is written most often in the following form (keep in mind that this is in the case when the two referential move in opposite direction!):

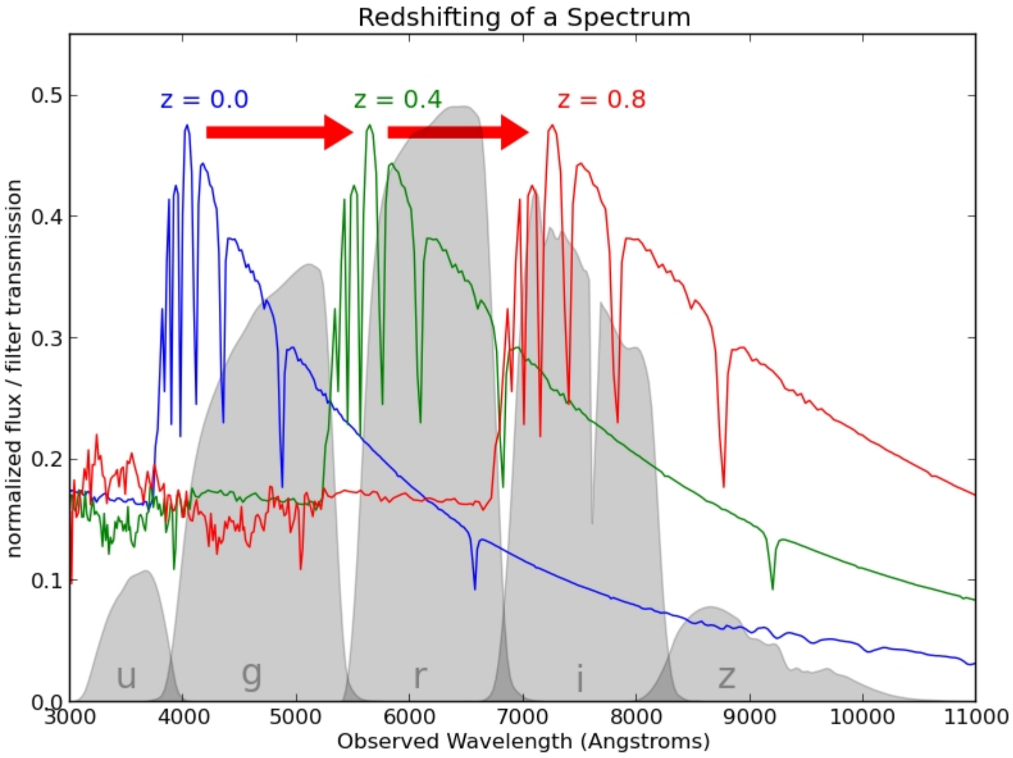
$$\boxed{\frac{f}{f'}=\frac{f_{\text{source}}}{f_{\text{observed}}}=\frac{1+\dfrac{v}{c}}{\sqrt{1-\dfrac{v^2}{c^2}}}=1+z=\sqrt{\frac{1+\beta}{1-\beta}}} \tag{12.1.943}$$

Therefore if we measure the both frequencies (supposing that we know what should be the source), then we can also obviously determine the speed v of the observed object.

Or in case of wavelength we have similarly:

$$\boxed{\frac{\lambda'}{\lambda}=\frac{\lambda_{\text{observed}}}{\lambda_{\text{source}}}=\frac{1+\dfrac{v}{c}}{\sqrt{1-\dfrac{v^2}{c^2}}}=1+z=\sqrt{\frac{1+\beta}{1-\beta}}} \tag{12.1.944}$$

When a spectrum can be obtained, determining the red shift is rather straight-forward: if you can localize the spectral fingerprint of a common element, such as hydrogen, then the red shift can be computed using simple arithmetic. But similarly to the case of star/quasar classification, the task becomes much more difficult when only photometric observations are available:



It must be recalled that the pulsation offset (and therefore frequency offset) that takes place here is due to a relative motion of the observer with respect to the source and not to something else (or respectively of the source relatively to the observer). Indeed, in our study of General Relativity (see section General Relativity page 5821), we will prove that there is a superposition of a shift because of the gravitational field surrounding the emitter that will be considered as caused by the space-time curvature.

Finally, for sceptics who want to check in another way that the Doppler phenomenon is well symmetric unlike the acoustic Doppler effect proved in the section of Music Mathematics, here's another approach:

First, consider that it is the source moving away. If we calculated by the classical relation proved in the section of Music Mathematics the frequency of the signal at the reception would be (see page 8212):

$$f_{\text{remoteness}}=f\dfrac{1}{1+\dfrac{v_{\text{source}}}{v_{\text{phase}}}}=f\dfrac{1}{1+\dfrac{v}{c}}=\dfrac{1}{\Delta t}\dfrac{1}{1+\beta} \tag{12.1.945}$$

and we must take into account the time dilation for f with (see section Special Relativity page 5659):

$$\Delta t=\dfrac{\Delta t'}{\sqrt{1-\left(\dfrac{v}{c}\right)^2}} \tag{12.1.946}$$

because the time interval of the fixed observer is longer than that of the source (time is faster for observer at rest).

It comes then:

$$\begin{aligned}f_{\text{remoteness}}&=\dfrac{\sqrt{1-\beta^2}}{\Delta t}\dfrac{1}{1+\beta}=f'\dfrac{\sqrt{1-\beta^2}}{1+\beta}=f'\sqrt{\sqrt{(1+\beta)(1-\beta)}}1+\beta\\&=f'\sqrt{\dfrac{(1+\beta)(1-\beta)}{(1+\beta)^2}}=f'\sqrt{\dfrac{1-\beta}{1+\beta}}\end{aligned} \tag{12.1.947}$$

and if it is the observer who moves away from the source we proved in the section of Music Mathematics that:

$$f_{\text{approach}}=f'\left(1-\dfrac{v_{\text{obs}}}{v_{\text{source}}}\right)=f'\left(1-\dfrac{v}{c}\right)=\dfrac{1}{\Delta t'}(1-\beta) \tag{12.1.948}$$

both relations are indeed symmetric in the special relativistic case (as expected for electrodynamics)!

Remark

Currently, astronomers have courses in astrophysics and their observations are generally studied in an astrophysical context, so there is less distinction between the two disciplines than before.

A very good example of the application of the Doppler effect is to explore the limits given by measuring the apparent speed. Let's see what it is:

12.1.16.1 Apparent speed

By measuring the apparent speed of movement of very fast objects in the sky (plasma jets, etc.), astrophysicists have obtained apparent displacement speeds exceeding the speed of light in vacuum!

In fact, it is an illusion that can occur if the speed of the object is very close to that of light it emits, so close enough to c.

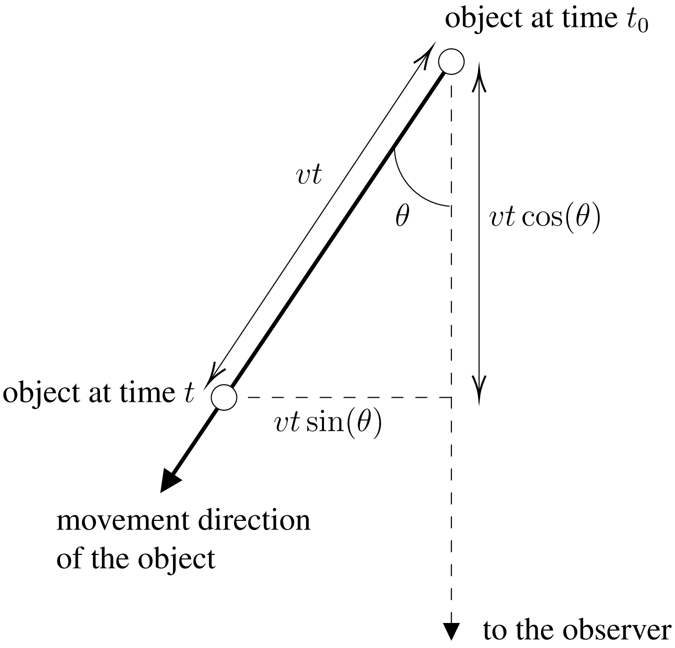


Figure 12.145: **Schematic idea behind the apparent speed**

The object emits light at time t_0, it does not instantly reach us but must travel a distance to get to us. We get it after the time:

$$t_1 = \frac{d}{c} \tag{12.1.949}$$

The object itself, moves with velocity v at an angle θ with the viewing direction, so at time t, the object moved of a distance vt. The light emitted by the object at time t must travel the distance (application of Pythagoras theorem):

$$d' = \sqrt{(d - vt\cos(\theta))^2 + (vt\sin(\theta))^2} \tag{12.1.950}$$

to reach us (the object has moved of a distance $vt\cos(\theta)$ in the direction of observation but moved away from the axis of observation of the distance $vt\sin(\theta)$), so we receive light that was emitted by the object at time t after a time t_2:

$$t_2 = t + \frac{d'}{c} = t + \frac{\sqrt{(d - vt\cos(\theta))^2 + (vt\sin(\theta))^2}}{c} \tag{12.1.951}$$

Between the two positions of the object, it has elapsed the time t but, viewed from the observer, the time interval between the reception of images of these two positions is:

$$t_2 - t_1 = t + \frac{d'}{c} = t + \frac{\sqrt{(d - vt\cos(\theta))^2 + (vt\sin(\theta))^2}}{c} - \frac{d}{c} \tag{12.1.952}$$

different from t!

For a small time interval t, we have, by doing a limited Taylor development:

$$\begin{aligned}t_2-t_1&=t+\frac{\sqrt{d^2-2dvt\cos(\theta)+v^2t^2\cos(\theta)+v^2t^2\cos^2(\theta)+v^2t^2\sin^2(\theta)}}{c}-\frac{d}{c}\\&=t+\sqrt{\frac{d^2}{c^2}-\frac{2dvt\cos(\theta)}{c^2}-\frac{v^2t^2}{c^2}}-\frac{d}{c}\cong t+\sqrt{\frac{d^2}{c^2}-\frac{2dvt\cos(\theta)}{c^2}}-\frac{d}{c}\\&=t+\frac{d}{c}\sqrt{1+\left(-\frac{2vtc\cos(\theta)}{d}\right)}-\frac{d}{c}\cong t+\frac{d}{c}\left(1-\frac{1}{2}\frac{2vt\cos(\theta)}{d}\right)-\frac{d}{c}\\&=t-\frac{vt\cos(\theta)}{c}=t\left(1-\frac{v}{c}\cos(\theta)\right)\end{aligned}\tag{12.1.953}$$

During this time interval, always from the point of view of the observer, the object appears to have moved on the sky plane by a distance of $vt\sin(\theta)$.

Thus, the apparent speed of the object is:

$$\boxed{v_{\text{app.}}=\frac{vt\sin(\theta)}{t_2-t_1}=\frac{v\sin(\theta)}{1-\dfrac{v}{c}\cos(\theta)}}\tag{12.1.954}$$

If we set the angle θ as being very close to a right angle, then we have the second term of the denominator that is very small which allows us with a Taylor expansion to write a relation that can be found quit often in high-school textbooks :

$$v_{\text{app}}\cong v\left(1+\frac{v}{c}\right)\tag{12.1.955}$$

Let us seek the maximum of this function to understand how such observation is possible by deriving relatively to θ and by seeking for what value the derivative is zero:

$$\frac{\mathrm{d}v_{\text{app}}}{\mathrm{d}\theta}=\frac{v\cos(\theta)}{1-\dfrac{v}{c}\cos(\theta)}-\frac{v}{c}\frac{v\sin^2(\theta)}{\left(1-\dfrac{v}{c}\cos(\theta)\right)^2}=0\tag{12.1.956}$$

and this vanishes after simplification of the denominator for:

$$v\cos(\theta)\left(1-\frac{v}{c}\cos(\theta)\right)-\frac{v}{c}v\sin^2(\theta)=v\cos(\theta)-\frac{v^2}{c}\left(\cos^2(\theta)+\sin^2(\theta)\right)=v\cos(\theta)-\frac{v^2}{c}=0\tag{12.1.957}$$

Hence:

$$\cos(\theta)=\frac{v}{c}\tag{12.1.958}$$

The apparent velocity is then:

$$v_{\text{app}}=\frac{v\sin(\theta)}{1-\dfrac{v^2}{c^2}}=\frac{v\sqrt{1-\cos^2(\theta)}}{1-\dfrac{v^2}{c^2}}=\frac{v\sqrt{1-\dfrac{v^2}{c^2}}}{1-\dfrac{v^2}{c^2}}=\frac{v}{\sqrt{1-\dfrac{v^2}{c^2}}}\tag{12.1.959}$$

and is equal to or greater than c if:

$$c=\frac{v}{\sqrt{1-\dfrac{v^2}{c^2}}}\Rightarrow c^2\left(1-\frac{v^2}{c^2}\right)=v^2\Rightarrow c^2-v^2=v^2\Rightarrow 2v^2=c^2 \tag{12.1.960}$$

Therefore:

$$v\geq\frac{1}{\sqrt{2}}c \tag{12.1.961}$$

Thus we see that it is possible to observe apparent movements faster than light, even though the subject is very fast indeed, but slower than c. As it is only an "illusion", there is no contradiction with the theory of relativity.

Knowing the speed of movement of a celestial object obtained using the Doppler effect and the apparent speed with the observations, it is easy for astrophysicists to determine the angle θ by doing a little bit elementary algebra from the following relation:

$$v_{\text{app}}=\frac{vt\sin(\theta)}{t_2-t_1}=\frac{v\sin(\theta)}{1-\dfrac{v}{c}\cos(\theta)} \tag{12.1.962}$$

12.2. Astrophysics

ASTROPHYSICS is an interdisciplinary branch of astronomy which mainly concerns physics and the study of the properties of objects in the Universe (stars, planets, galaxies, interstellar medium for examples) as their luminosity, density, temperature and their chemical composition. The first scientific approaches in this area date from the early 119th century (holocene calendar).

> ❞ *We have uncovered wonders undreamt by our ancestors who first speculated on the nature of those wondering lights in the night sky. We've crossed the Solar System and sent ships to the stars. But we continue to search. We can't help it! A central element of the human future, lies far beyond the Earth. If we crave some cosmic purpose, then let us find ourselves a worthy goal...* ❞

quote 12.2:5539.#69

12.2.1 Stars

Before addressing the mathematical formalism on the dynamics of stars, we wanted following readers requests, write a small popularized introduction to complete the general knowledge on this field.

The stars are gaseous celestial body whose mass goes from 0.05 solar mass ($\sim 2\cdot 10^{30}$ [kg]) to more than 300 solar masses[21]. The brightness of a star (its power radiation) ranges from 10^{-6} to 10^{6} times that of the Sun. Roughly, when the mass doubles, brightness is multiplied by. Most of the stars visible to the naked eye in our skies are blue giants of 10^4-10^5 times more luminous than the Sun; they represent only 10% of stars that inhabit our Galaxy, the remaining 90% being less luminous than the Sun.

The Astronomers (of Harvard between 11918-11928 according to holocene calendar) have developed a method of classification of stars based on their position in the spectrum, of the spectral absorption lines (spectroscopy). Formerly classified from A to Q, the evolution of the spectrometry allowed their grouping and organization. Classes are now defined by the letters OBAFGKM (one mnemonic for remembering the sequence is: **O**h **B**e **A** **F**ine **G**irl/**G**uy, **K**iss **M**e), and each is divided into 10 subclasses, rated from 0 to 9. The spectral classification (taken from a continuous spectrum which summarizes only certain lines of the spectrum after passing of light in a given medium) can be crossed with the lighting classes so that we can infer the temperature at the surface of the star (we will prove later how to get this information):

---

[21] UY Scuti has the largest radius know at the day we write these lines but large radius does not make it the most massive, or heaviest star. That honour goes to R136a1, which weights about 226 times the mass of the Sun but only 30 solar radii.

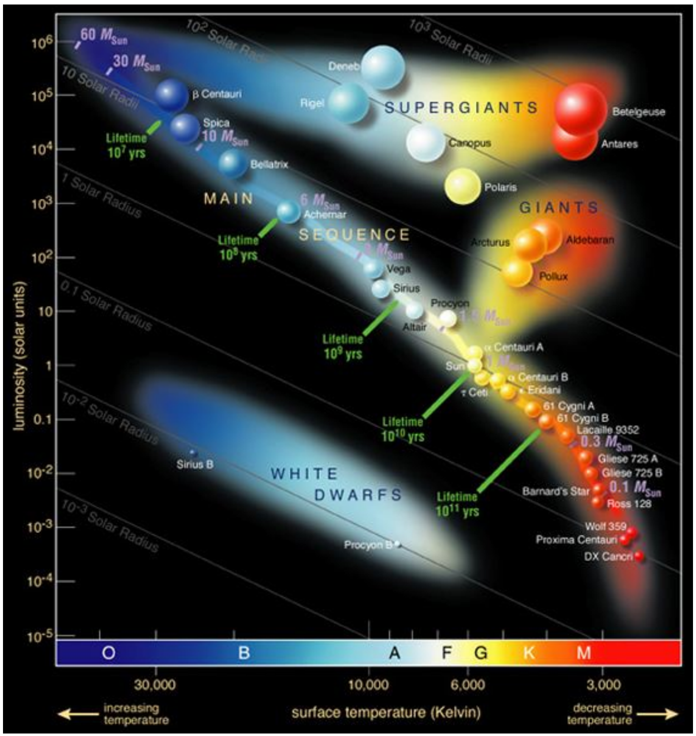

Figure 12.146: **Hertzsprung-Russel Diagram example (source: Wikipedia)**

And the corresponding hypothesized path evolution of our Sun (actually a G2V-type star, aka yellow dwarf) on this same diagram (notice on the sequence below that the external layer of our Sun will cool down a little bit on the path of its sequence while growing in size!):

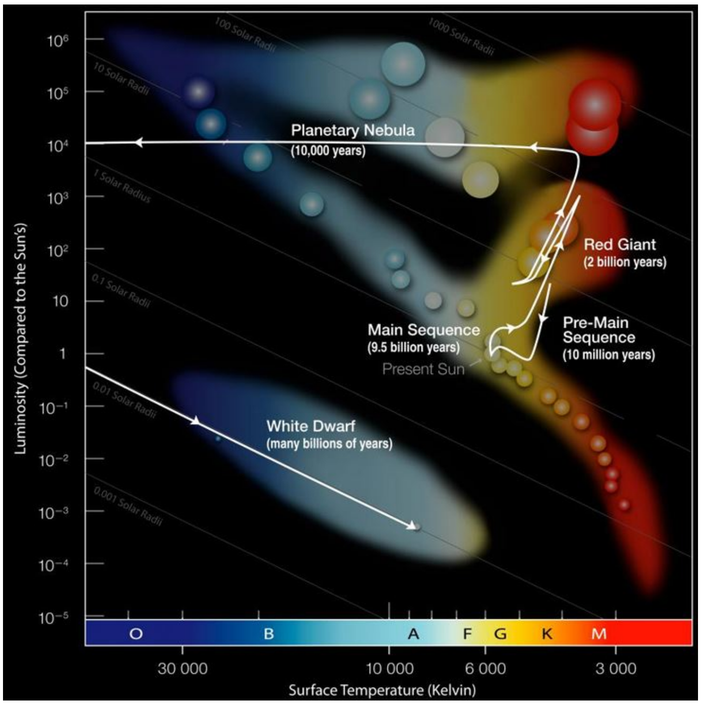

Figure 12.147: **Sun path on Hertzsprung-Russel**

Where the colors and temperature association are based "obviously" on the color of a black-body as experimental measurements show that stars behaves almost the same as a perfect black-body[22] (see section Statistical Mechanics page 3704).

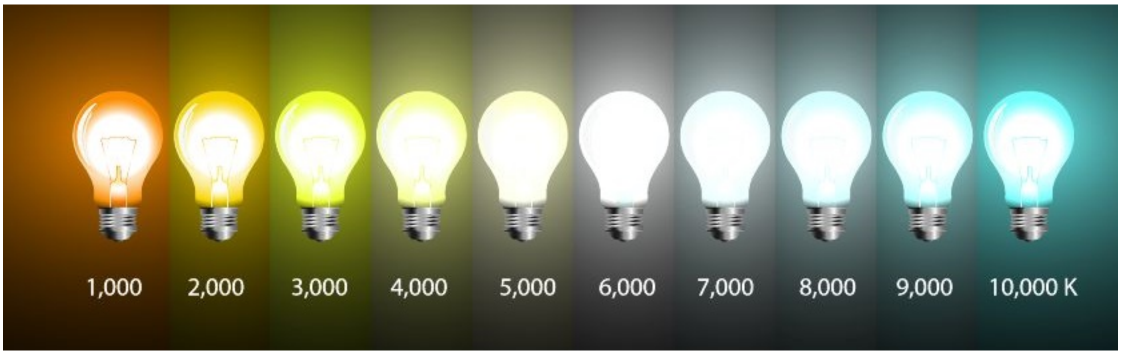

Figure 12.148: Peak color of a black body at a given temperature

As it evolves, each star describes a particular curve on the HR diagram: it begins by following the "Hayashi-path" (proto-star and after one of the existing tar) until it reaches the main sequence in which it operates as its core burns hydrogen. When beginning the burning of helium, it goes back up where red giants are concentrated and remains there until nuclear fusion stops; it then collapses on itself to join the White Dwarfs or in the case of a certain value of solar masses, neutron stars, Black Holes, or if its mass is very high, exploding as supernovae.

The O stars were discovered in the late 119th century (holocene calendar). They are hot and their spectra look like those of nebulae. The B are helium stars, A hydrogen stars. The predominant component of F is calcium. G are of the same type as the Sun (actually a G2V-type star, aka yellow dwarf) and K differ very little bit. M are characterized by titanium oxide and S of zirconium oxide, while R and N contain hydrocarbons and cyanogen.

---

[22] This is also why some LED brands have the color given as a temperature

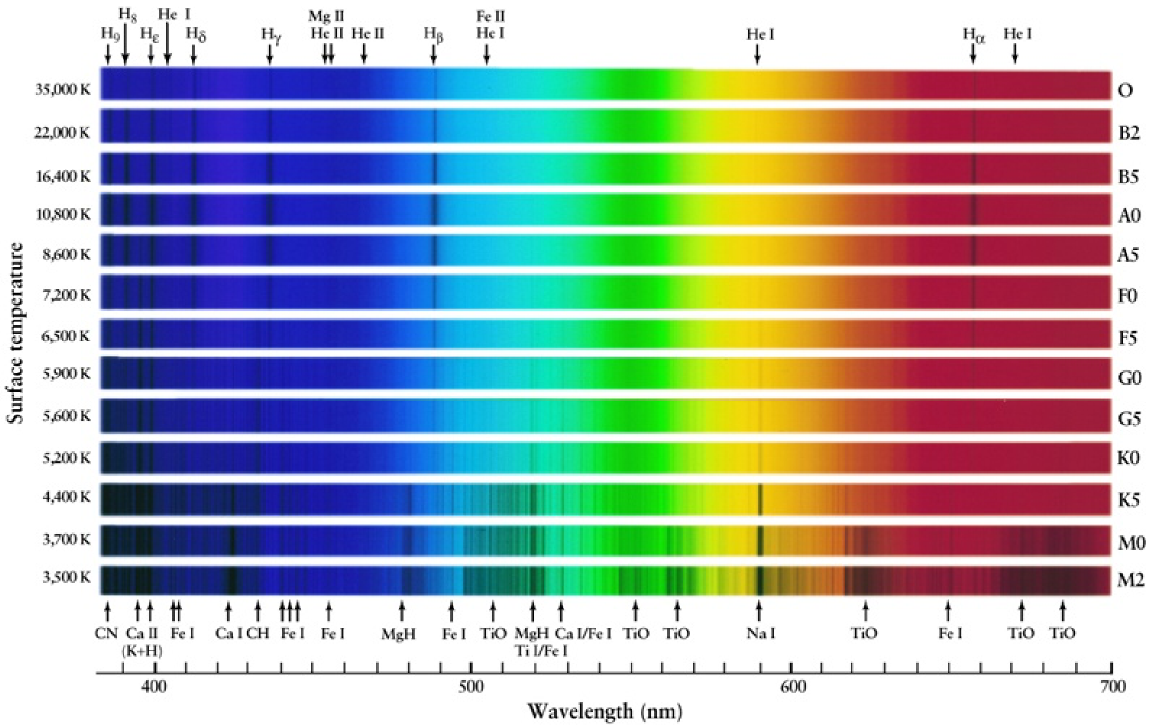

Figure 12.149: Typical stars temperature and related spectrum with absorption lines (source: Alberta University

Remark

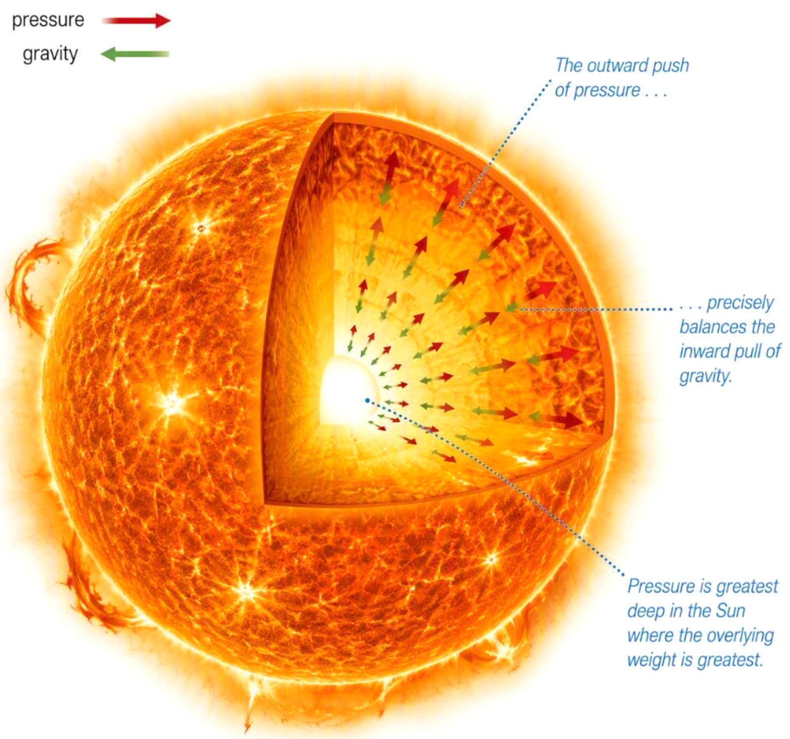
An "absorption line" is any dark line in a spectrum produced when atoms, ions, or molecules absorb light at specific wavelengths, regardless of where this occurs, such as in stars, planets, interstellar clouds, or laboratories. A "Fraunhofer line" is a specific type of absorption line observed in the Sun's spectrum, first cataloged by Joseph von Fraunhofer and caused by absorption in the cooler layers of the solar atmosphere. Thus, all Fraunhofer lines are absorption lines, but absorption lines found in other astronomical objects are not generally called Fraunhofer lines.

Therefore a star of the mass of the Sun after a stint on the main sequence, becomes a red giant, eventually a planetary nebula (ejection of fuel of the star at long distances), before ending his life as a White Dwarf. The end as supernovae cannot be shown in this diagram because of their luminosity that is to high. Neutron star and Black Holes are in the same path than White Dwarfs (lower on the right than Procyon B).

A star is initially in hydrostatic equilibrium. Gravitational forces[23] due to its mass are compensated by the internal pressure forces due to the elevated temperature maintained by thermonuclear reactions at low density and to the degeneracy pressure of electrons:

---

[23] Remember that we will see during our study of General Relativity that the gravitational force is fictional and we should us the expression "gravitational interaction" instead.



pressure
gravity
The outward push of pressure . . .
. . . precisely balances the inward pull of gravity.
Pressure is greatest deep in the Sun where the overlying weight is greatest.

The temperature at the very center of the Sun (actually a G2V-type star, aka yellow dwarf) is estimated to be about $15,000,000$ [K] and the density at the center of the hydrogen/helium supercrushed "plasma" core is estimated to be about $150\,[\text{g}\cdot\text{cm}^{-3}]$ (approximately 10 times the density of gold). The solar interior fluid is 100 to $10,000$ times more viscous than water. Fluids of comparable viscosity would be honey or ketchup (non-newtonian fluid).

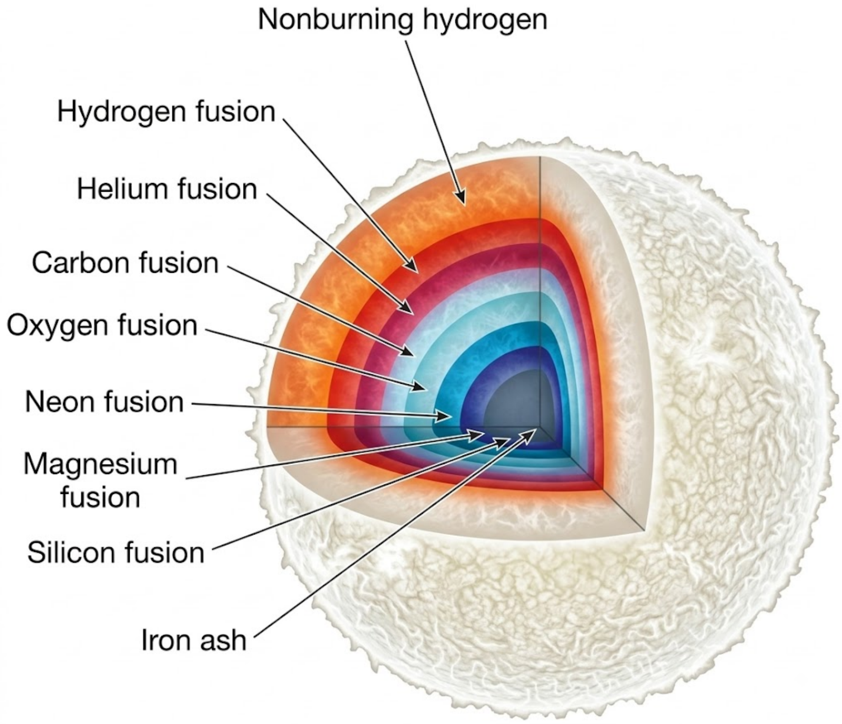
www.astrophoto.fr

Figure 12.150: **Photo of Sun's surface (sunspot AR4455) with a Soleye 3000 and $\text{H}\alpha$ filter (credit: Thierry Legault)**

A star spends almost 90% of his life to fuse hydrogen into helium that builds up in the center (for the first famous scientific study and observation of Sun's composition *see* stoney1869physical. During this phase, it evolves into the "main sequence" of the Hertzsprung-Russian diagram.

For a low mass Main Sequence star, hydrogen fusion is the first energy source that provides radiation pressure to maintain the hydrostatic equilibrium. When hydrogen fusion ends, the star begins to undergo structural changes, and it begins to become a red giant (helium fusion) through what we name a "helium flash". At the end of the life of a low mass star, the core collapses until the electrons provide a source of pressure to withstand the collapse, and at this stage the star is a White Dwarf. For higher mass stars, the early stages of life are the same, but the core of these stars reach higher temperatures, so they can burn more massive species, like Carbon, Oxygen, Neon, Magnesium, and Silicon. Towards the end of its life, a high mass star's core will look like the layers of an onion.



The core of a high mass star will eventually generate iron, but when the core tries to fuse iron, it will die in a catastrophic explosion. The problem is that unlike Hydrogen, Helium, Carbon, etc., the fusion of iron does not release energy (see section Nuclear Physics page 5064). When the core contains enough iron, the star implodes in seconds, and all of the mass of the outer part of the star hits the core and rebounds, and the rebound sends a shockwave outward pushing all of the material outside of the core into space in a tremendous explosion, named a "supernova[24]" (the year in the legend below is given according to holocene calendar):

---

[24] Between 12000 and 12022 (holocene calendars) more than $110,000$ supernova were observed by various observatories amonge these approximately $14,000$ were Type I supernovae and the remaining were Type II suernovae.

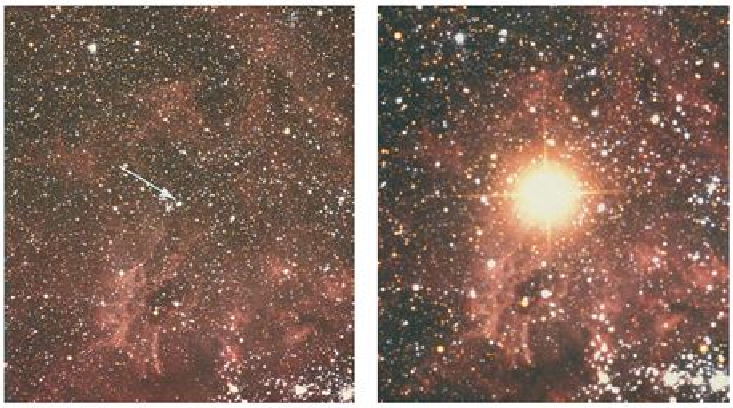


Figure 12.151: Region of the sky before and after the 11987 supernova in visible light

When the helium mass of a star becomes sufficient, the increase in pressure causes an increase of the temperature thereby initiating the fusion of helium ("helium flash") into carbon, oxygen and neon creating a second combustion front inside the first. For a star of one solar mass, reactions stop at this stage. The star radius increase and its surface temperature decrease until stabilization. It becomes a red giant 10^4 times more luminous than before.

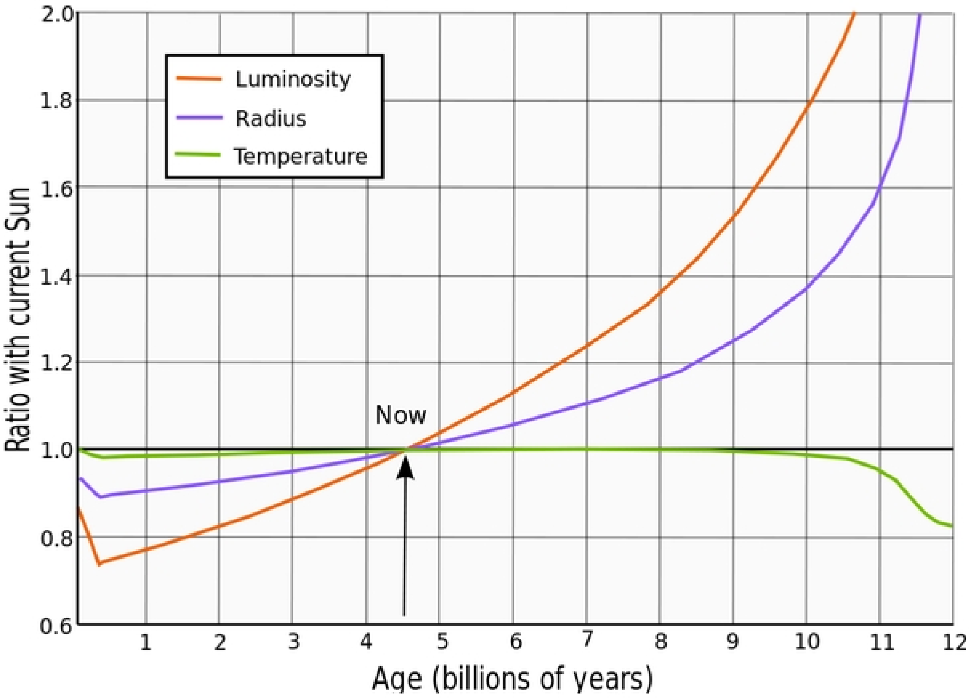

Figure 12.152: Evolution of temperature, radius, luminosity of our Sun as function of time

It goes through various phases of instability and eventually gradually expel its outer layers, forming a "planetary nebula" (from a fraction of parsecs like in size like our Solar System to a little bit more of 1 parsec - approximately 4 light years - for the biggest known at this date).

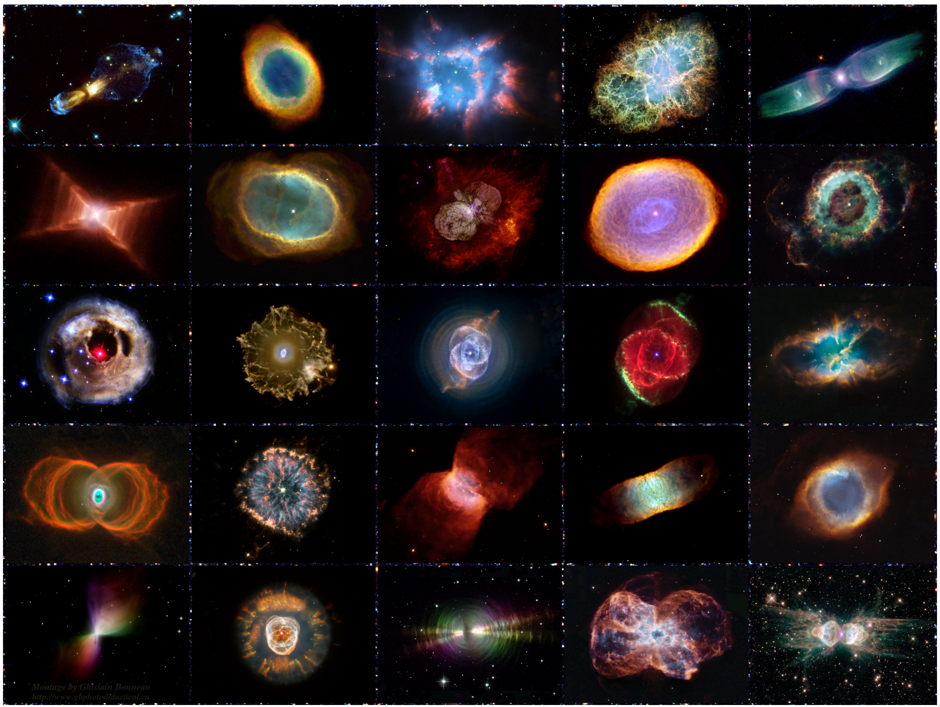

Figure 12.153: **Planetary Nebula gallery (source: Hubble Space Telescope)**

Its core, with a density of several tons per cubic centimetre, cools down slowly: it becomes a "White Dwarf" (we will discuss this process mathematically below). The balance in its core is maintained by the pressure of degeneration of electrons.

For a more massive star, the internal temperature becomes quite important so that the carbon and oxygen can fusion into silicon. In turn, if there is enough mass, silicon will fusion into iron. Combustion fronts develop in a pattern said of "onion skins" (see prior previous figure). As iron is the most stable nucleotide, it is at the bottom of the valley of stability (see section Nuclear Physics page 5062). It can not fusion or split. When the density reaches a critical value (this corresponds to a total mass of the star of more than 8 solar masses!!!), electron degeneracy pressure can no longer maintain the balance against gravity. In a tenth of a second, the iron core collapses. The other layers of the heart of the star rush towards the collapsed core in the for a wave whose maximum speed corresponds to the sonic radius.

The core density then becomes really huge. There occur inverse β^- reactions where protons capture electrons forming neutrons (!!!) and releasing a flow of neutrinos. When the core of the star reaches the nuclear density of approximately $10^{18}\;[\text{kg}\cdot\text{m}^{-3}]$, the compaction stops roughly (the remaining radius at this stage is about 10 [km] only!). The outer layers of the core bounce by a super elastic shock and come into expansion. When this reflected shock wave reached the sonic radius, the temperature rises so high that give him a value is almost meaningless. The material undergoes a complete photo-disintegration (all nucleotides are disaggregated into nucleons gas). Finally by an unclear mechanism, all the outer layers of the star are ejected into space: it is a "type II supernovae".

The collapsed core, made almost entirely of neutrons, will be rotating rapidly if the original star had a non-zero angular momentum (conservation of angular momentum oblige!). The magnetic field is also preserved and far exceeds anything that will probably never be feasible a laboratory. This causes a synchrotron beam which gives the illusion that the star flashes. This is why these young "neutron stars" are named "pulsars".

For very massive stars (above 50 solar masses), the total mass of the core that collapses could exceed 3 solar masses. In this case, gravity becomes such that its mass collapses beyond the last repulsive forces and compacted into a singularity. The curvature of space becomes such that almost (without going into the details of some theories that have until now not been verified) no material information or radiation can escape beyond the horizon or a volume named the "Schwarzschild sphere". This is a "Black Hole". Anything that falls inside loses his identity. A Black Hole has only three properties: its mass, angular momentum and electric charge. We say that a Black Hole has "no hair". Moreover, such a singularity should always be hidden by a horizon, be: "dressed" (for more details see the section of General Relativity).

Remark

Depending or your human visual accuracy (myopia) and depending on the conditions (ambient light, clouds, weather, presence of the Moon) and your position on Earth you should be able to see only between 0 to $11,000$ stars in the night sky (when modern professional telescopes car resolve hundred of billions of stars).

To give an idea of the scales you can see the figure below:

12.2.1.1 Stellar Physics

We will now see how new stars can be born from huge gas clouds that extend between the stars in galaxies. The interstellar medium is a potential source of new stars, which once completed their life (as a red giant or supernova) can inject some of their material in outer space.

In fact, nobody really knows in this beginning of the 121st century (holocene calendar) the details of how an interstellar cloud leads to a star because it is a very difficult problem, mainly because of the emergence of a hierarchy of structures, sub-structures, etc. in the cloud as it collapses on itself. Turbulent motions appear, which can not be described simply by the hydrodynamic equations (see section Continuum Mechanics page 3811). Further complications arise when we consider the magnetic field on the gas contraction, or supernova explosions in the cloud...

At least, can we give the necessary conditions for a star to form in an interstellar cloud. For this, several barriers must actually be completed. A first thermal barrier. A second rotational barrier is: a protostar that contracts rotates faster and faster and can literally explode if its speed becomes too high (conservation of angular momentum). Let's examine these two effects.

12.2.1.1.1 Collapse of an Interstellar Cloud

Two opposing forces are present in a cloud of mass M and radius R: an autogravitation (a force) which tends to contract the cloud, and thermal pressure force, which tends to explode it.

We can quantify these two opposite forces in terms of energy: the cloud has a gravitational potential energy (negative) and a kinetic energy (positive) due to thermal agitation of the molecules.

We know (see section Classical Mechanics page 3351) that the gravitational potential energy of two masses m and m' of particles separated from a distance r is written:

$$E_p = -\frac{Gmm'}{r} \tag{12.2.1}$$

So the external potential energy of a spherical cloud (...) of mass M and radius R is of the order of:

$$E_p \cong -\frac{GM^2}{R} \tag{12.2.2}$$

Remark

Some practitioners (this is our case) prefer for the following developments use the internal potential energy that is given for recall by (see the proof in the section of Classical Mechanics):

$$E_p \cong -\frac{3}{5}\frac{GM^2}{R} \tag{12.2.3}$$

In a gas in thermodynamic equilibrium, a particle has a kinetic energy (see section Continuum Mechanics page 3897) of $kT/2$ by degree of freedom (translation, rotation, etc.). So if μ is the average mass of a molecule of the cloud, the total kinetic energy of the latter will be expressed:

$$E_c=\frac{3}{2}kT\frac{M}{\mu}\cong kT\frac{M}{\mu} \tag{12.2.4}$$

The cloud then collapses if its total mechanical energy is negative, or (according to the previous approximation):

$$kT\frac{M}{\mu}\leq\frac{GM^2}{R} \tag{12.2.5}$$

The above equation defines the "Jean's mass" (assuming a spherical and homogeneous distribution). This is the minimum mass (limit) at a given temperature T and density ρ for a cloud begins to collapse until another physical process may intervene to stop the contraction of the gas.

By eliminating the radius with:

$$M=\frac{4\pi\rho r^3}{3} \tag{12.2.6}$$

In the previous relation, we get:

$$M\geq\frac{kT}{G\mu}R=\frac{kT}{G\mu}\left(\frac{4\pi\rho r^3}{3}\right)^{1/3}\Rightarrow M^{2/3}\geq\frac{kT}{G\mu}\left(\frac{3}{4\pi\rho}\right)^{1/3}\Rightarrow M\geq\left(\frac{kT}{G\mu}\right)^{3/2}\left(\frac{3}{4\pi\rho}\right)^{1/2} \tag{12.2.7}$$

If we would not have make the choice of the external potential, but rather the internal one (more accurate in our point of view) and we did not approximate $2/3\cong 1$ the final result would have been:

$$M\geq\left(\frac{5kT}{G\mu}\right)^{3/2}\left(\frac{3}{4\pi\rho}\right)^{1/2} \tag{12.2.8}$$

That is traditionally written as:

$$\boxed{M_J=\left(\frac{5kT}{Gm}\right)^{3/2}\left(\frac{3}{4\pi\rho}\right)^{1/2}} \tag{12.2.9}$$

Therefore if $M_{\text{cloud}}>M_J$ then the cloud collapse!

As they are many approximations, astrophysicists prefer to write this last relation as:

$$M_J\cong C\left(\frac{kT}{G\mu}\right)^{3/2}\frac{1}{\sqrt{\rho}} \tag{12.2.10}$$

where C is obviously a constant without units.

PDS 70 (very young T Tauri star in the constellation Centaurus. Located at 370 light-years from Earth, it has a mass of 0.76 solar masses and is approximately 5.4 million years old) is special as it is the only protoplanetary disk so far in this early 121st century where all astronomers agree that we have found forming planets (PDS 70b, PDS 70c) caught in the act of gravitational collapse:

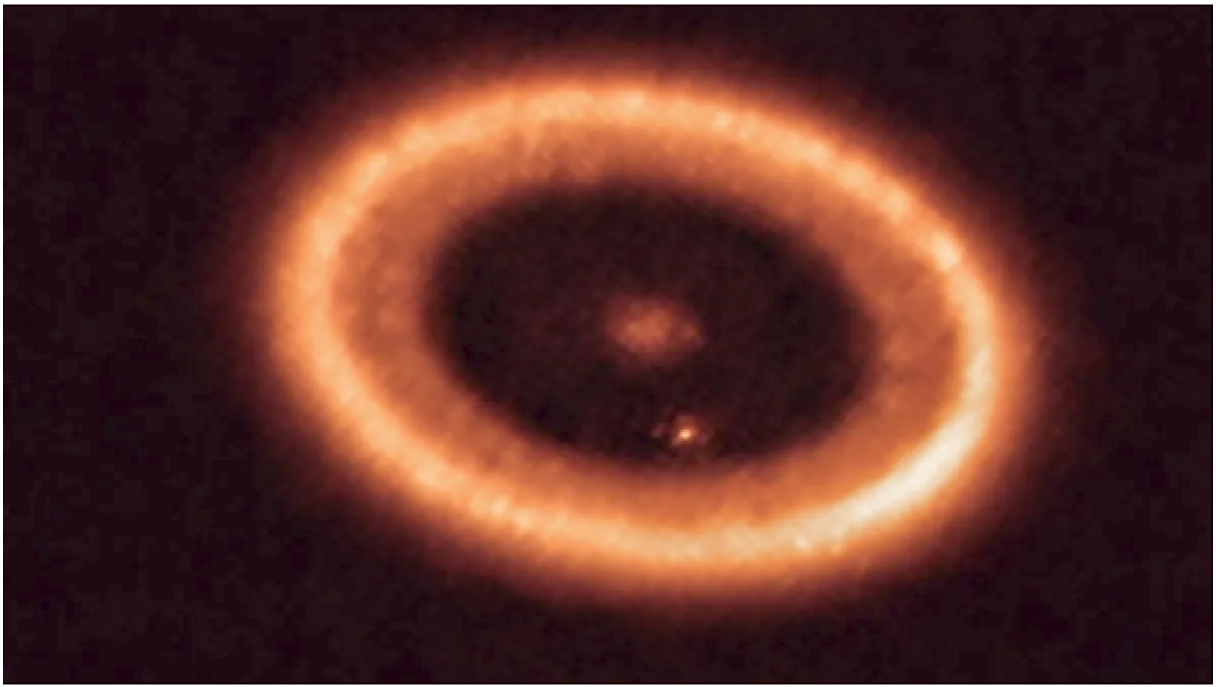

Figure 12.157: **Protoplanetary disk around the infant star PDS 70, which may contain the seeds of a third planet (source: ALMA (ESO/NAOI/NRAO)/Benisty et al.)**

12.2.1.1.1.1 Limit Mass Cloud for Ionization (rogue planets)

Now let us come back on the relation:

$$M_J=\left(\frac{5kT}{G\overline{m}}\right)^{3/2}\left(\frac{3}{4\pi\rho}\right)^{1/2} \tag{12.2.11}$$

A famous question is what is the mass required by a hydrogen cloud to start nuclear fusion and become a star[25]. For this, we can say in a first approximation that for the fusion, hydrogen atoms must have a distance equal to their radius such that we have for the density:

$$\rho=\frac{m_{\text{H}}}{\dfrac{4}{3}\pi r_0^3}=\frac{1.67\cdot 10^{-27}}{\dfrac{4}{3}\pi(0.5\cdot 10^{-11})^3}\cong 3,189\,[\text{kg}\cdot\text{m}^{-3}] \tag{12.2.12}$$

where for comparison, density for iron is $7,874\,[\text{kg}\cdot\text{m}^{-3}]$. We will also take $\overline{m}\cong m_p=1.6726219\cdot 10^{-27}$ [kg] (we neglect the mass of electrons as it is almost $1,800$ smaller) and for temperature that of the fusion of hydrogen[26] $T=T_i=10^6$ [K].

Therefore:

$$\boxed{M_i=\left(\frac{5kT_i}{G\overline{m}}\right)^{3/2}\left(\frac{3}{4\pi\rho}\right)^{1/2}\cong 1.33\cdot 10^{29}\cong 0.066M_{\odot}} \tag{12.2.13}$$

This value perfectly match the value given by then french version of Wikipedia (given without proof...).

With the 10 security factor for T_i we would have:

$$M_i\cong 0.002M_{\odot}=0.2\%M_{\odot} \tag{12.2.14}$$

In comparison Jupiter is 0.1% of the mass of the Sun...

Therefore for an initial mass less than $0.066M_{\odot}$ the gas sphere liquefies or solidifies and stabilized in the form of a planet. Jupiter as we have just see has a mass that is not for very near this limit value and we observed with telescopes that the planet is still very slowly contracting.

Such bodies are named "Sub-Brown Dwarfs", sometimes referred to as "rogue planets".

---

[25] Notice that some astrophysicists thinks that in some special configuration cases, some huge gas clouds may directly collapse in super Black Holes instead of creating a star (or smaller celestial objects).

[26] We have proved that the ionization energy of hydrogen in the section of Corpuscular Quantum Physics was 13.6 [eV], hence $157,821$ [K] but to avoid re-coupling we take a security factor of 10.

12.2.1.1.1.2 Limit Mass Cloud for Fusion (Black Dwarf)

The name "Black Dwarf" has also been applied to substellar objects that do not have sufficient mass, less than approximately $0.08M_\odot$, to maintain hydrogen-burning nuclear fusion. These objects are now generally named "brown dwarfs", a term coined in the 11970s (holocene calendar). Black dwarfs should not be confused with Black Holes or neutron stars.

Beyond ionization mass limit, it is an ionized gas ball that will continue gravitational collapse. If during contraction, the temperature of 10^7 [K] is not reached, the nuclear reactions can be triggered and it is the quantum nature of repulsive forces that will oppose gravity. Electrons are fermions (see section Statistical Mechanics page 3571), the principle of Pauli exclusion (see section Corpuscular Quantum Physics page 4672) prevents the stack of Electron in the same volume of phase space. This is equivalent to a high pressure which is well above the thermal pressure of the atoms.

The mass that can be stabilized in this state is still:

$$E_p=\frac{3}{5}\frac{GM^2}{R}=E_c=\frac{3}{2}NkT \tag{12.2.15}$$

As $T_f\cong 10^7$ [K], the electrons are non-relativistic. The linear moment is such that:

$$\frac{p^2}{2m}=\frac{3}{2}kT\Leftrightarrow p=\sqrt{2m_e\frac{3}{2}kT}=\sqrt{3m_ekT} \tag{12.2.16}$$

From the incertitude principle (see section Wave Quantum Physics page 4719):

$$[x,p_x]=\mathrm{i}\hbar \tag{12.2.17}$$

Roughly:

$$x=\frac{\hbar}{p}=\frac{h}{2\pi p}=\frac{h}{2\pi\sqrt{3m_ekT_f}}\cong 5.42912\cdot 10^{-12}\;[\text{m}] \tag{12.2.18}$$

to compare with the previous $r_0=0.5\cdot 10^{-10}$ [m]...

Therefore:

$$\rho=\frac{m_\text{H}}{\dfrac{4}{3}\pi x^3}=\frac{1.67\cdot 10^{-27}}{\dfrac{4}{3}\pi(5.42912\cdot 10^{-12})^3}\cong 2.49\cdot 10^6\;[\text{kg}\cdot\text{m}^{-3}] \tag{12.2.19}$$

For the protons, that are $1,800$ times more massive, the minimum volume is much smaller and can be neglected at this level of our discussion.

We use now the same relation as previously but where we take T_f instead of T_i and $\overline{m}=m_e=9.10938356(11)\cdot 10^{-31}$ [kg] as the proton mass as plasma experiences and intuition gives that electrons because of their small mass take the most kinetic energy (in comparison to the proton for the same charge... or as in heated liquids where small molecules are much more agitated than big one):

$$\boxed{M_f=\left(\frac{5kT_f}{G\overline{m}}\right)^{3/2}\left(\frac{3}{4\pi\rho}\right)^{1/2}\cong 1.83\cdot 10^{30}\cong 0.92M_\odot} \tag{12.2.20}$$

Therefore theoretically we have so far:

- $M_i < 0.066M_\odot$ we have a big gas planet of the style of Jupiter or Saturn ("Sub-Brown Dwarfs" or "rogue planets" for recall).
- $0.066M_\odot < M_f < 0.92M_\odot$ we have a ionized hot star at the limit of starting a nuclear fusion it's for recall a "Black Dwarf" or more suited named a "Brown Dwarf".
- For $M_J > 0.92M_\odot$ we have then a star able to initiate thermonuclear fusion.

Brown Dwarf seem to be very difficult to observe. As far as we know the first one was directly observed in 12016 (holocene calendar) only (HD 4747 B)... because of their low surface energy emitting.

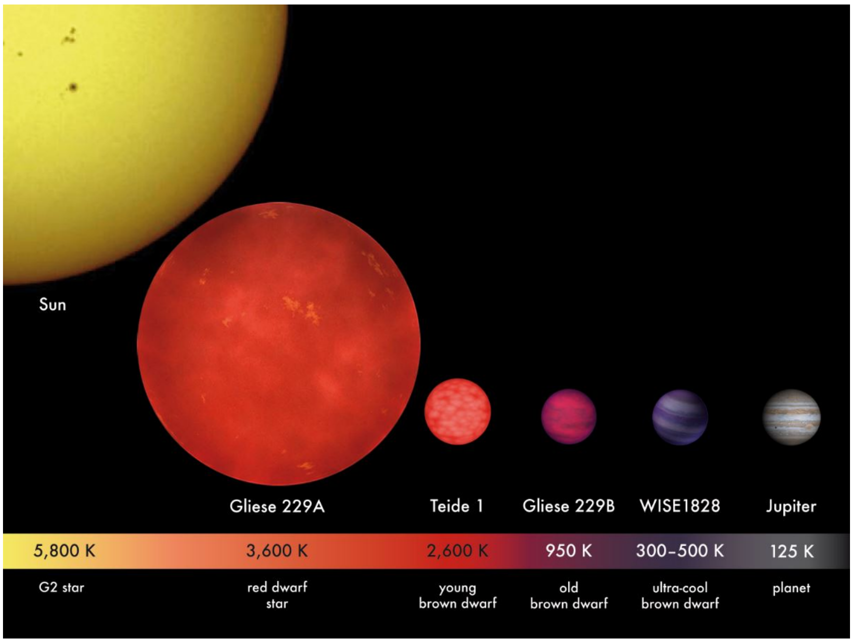

Figure 12.158: **Sun in comparison of various dwarf stars and Jupiter**

The developments above are obviously approximations and depends on many other factors. For example, Proxima Centauri, located just 4.2 light-years away has 12% of the mass of the Sun, and it is estimated to be just 14.5% the size of the Sun (actually a G2V-type star, aka yellow dwarf) with a diameter of about $200,000$ [km] (just for comparison, the diameter of Jupiter is $143,000$ [km], so Proxima Centauri is only a little larger than Jupiter).

But that's not the smallest star ever discovered! The smallest known star right now is OGLE-TR-122b that is part of a binary stellar system. This Red Dwarf has its radius accurately measured!: 0.12 solar radii. This works out to be $167,000$ [km]. That's only 20% larger than Jupiter. You might be surprised to know that OGLE-TR-122b has 100 times the mass of Jupiter.

It seems that in July 12017 (holocene calendar) even a smallest star was observed (but we need confirmation), EBLM J0555-57Ab. It seems that this star has a mass equivalent to 8% to that of our Sun and is as big as Saturn...

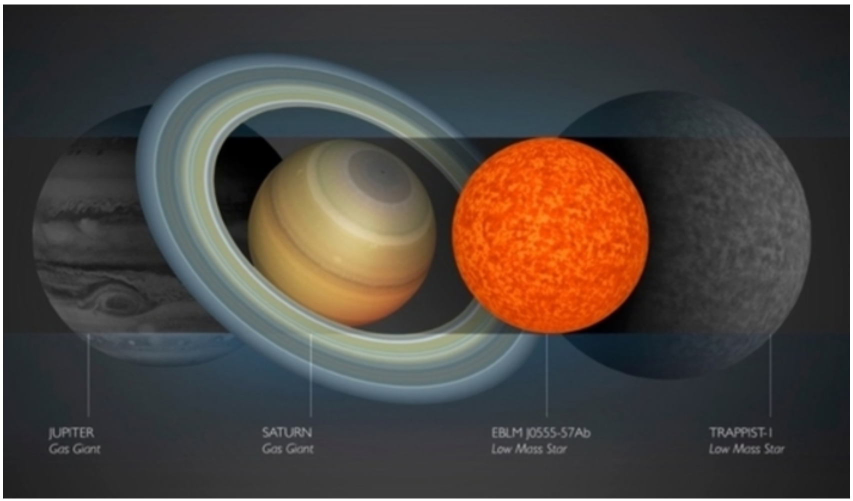

Figure 12.159: **EBLM J0555-57Ab smallest known star] (source: ?)**

12.2.1.1.1.3 Entropy of a gas collapsing under gravity

The entropy of a collapsing gas, particularly in the context of star formation, captures the fascination of internet discussions and social media debates for several reasons. This concept delves into the intersection of astrophysics, thermodynamics, and the mysteries of the universe - topics that naturally intrigue a broad audience of science enthusiasts, educators, and laypersons alike.

Entropy, often (wrongly) associated with disorder, seems paradoxical in the context of star formation. When a massive cloud of gas and dust collapses under its own gravity to form a star, the process appears to reduce disorder by condensing scattered particles into a compact, organized structure. This seemingly defies the principle that entropy should always increase in an isolated system. Social media discussions frequently center on this apparent contradiction, exploring how the second law of thermodynamics applies to star formation. People find this intellectual challenge captivating because it invites them to question and deepen their understanding of the natural world.

Rather than doing rhetorical explanations, let us do the maths as it is the tradition in this textbook (all the developments are almost a simple copy paste of a PDF provided by Rick Bradford)!

Let us consider a system of n particles of mass m in a gravitationally bound state. We shall assume thermodynamic equilibrium prevails within the gas cloud (though not necessarily between the cloud and its surroundings - see below). Thus, the gas has some temperature, T. The average kinetic energy per particle is, for non-relativistic motion in three spatial dimensions is given as we know by:

$$E_c = \frac{3}{2}kT \tag{12.2.21}$$

The virial theorem (see section of Continuum Mechanics page 3897) tells us that the average total kinetic energy:

$$\bar{E}_c = \frac{3}{2}nkT \tag{12.2.22}$$

is equal to:

$$\bar{E}_c=\frac{3}{2}nkT=-\frac{1}{2}E_p \qquad (12.2.23)$$

where E_p is the average total potential energy. Since, for a large gas cloud, the total potential energy will not vary significantly in time, we can drop the requirement for averaging. We thus have:

$$E_p=-3nkT \qquad (12.2.24)$$

But the gravitational potential energy of a spherically symmetric mass distribution of total mass $M=n\cdot m$ and radius R is:

$$E_p=-\eta\frac{GM^2}{R} \qquad (12.2.25)$$

where η is a dimensionless constant of order unity depending on the distribution (e.g. $\eta=3/5$ for uniform density as proven in the section Mechanics at page 3356). In terms of the volume of the cloud:

$$V=\frac{4}{3}\pi\mathrm{R}^3 \qquad (12.2.26)$$

Therefore:

$$kT=\frac{\eta}{3}\left(\frac{4\pi}{3}\right)^{1/3}Gm^2\cdot\frac{n}{V^{1/3}} \qquad (12.2.27)$$

Now the entropy of an ideal gas is given by the Sackur-Tetrode equation (see section Continuum Mechanics page 3934):

$$S_{\text{gas}}=Nk\left\{\frac{5}{2}+\log\left[\left(\frac{mkT}{2\pi\hbar^2}\right)^{3/2}\cdot\frac{V}{N}\right]\right\} \qquad (12.2.28)$$

This gives the absolute total entropy. For our purposes we only need know the change in entropy between two states of different volume and temperature ΔS_{gas}. Thus we can simplify the previous relation to:

$$S_{\text{gas},i}-S_{\text{gas},f}=\Delta S_{\text{gas}}=Nk\log\left\{\left(\frac{T_i}{T_f}\right)^{3/2}\left(\frac{V_i}{V_f}\right)\right\}+c^{te} \qquad (12.2.29)$$

Using:

$$kT=\frac{\eta}{3}\left(\frac{4\pi}{3}\right)^{1/3}Gm^2\cdot\frac{n}{V^{1/3}} \qquad (12.2.30)$$

we can substitute for T in terms of V, and hence the prior-previous relation can be simplified further:

$$\Delta S_{\text{gas}}=Nk\log\left\{\left(\frac{V_f^{1/3}}{V_i^{1/3}}\right)^{3/2}\left(\frac{V_i}{V_f}\right)\right\}+c^{te}=Nk\log\left(\frac{V_i^{1/2}}{V_f^{1/2}}\right)=2Nk\log\left(\frac{V_i}{V_f}\right) \qquad (12.2.31)$$

In passing we note that the total energy of the gas cloud is:

$$E_{\text{gas}}=E_c+E_p=\frac{E_p}{2}=-\frac{3}{2}\mathrm{nkT}=-\frac{\eta}{2}\cdot\frac{GM^2}{R} \qquad (12.2.32)$$

From the above we note that:

- The total energy of the gas is negative (inevitably because it is a gravitational bound system - we could not have employed the virial theorem otherwise)
- As the cloud collapses (R reduces) the magnitude of the energy increases, i.e. the absolute energy E_{gas} decreases
- As the cloud collapses (R reduces) the temperature increases
- From the two previous points above it follows that the gas cloud has a negative specific heat (the temperature increases as energy is removed from it)
- From:

  $$\Delta S_{\text{gas}} = 2nk\log\left(\frac{V_i}{V_f}\right) \tag{12.2.33}$$

  as the cloud collapses (R and hence V reduces) the entropy of the gas has decreased.

Hence a collapsing gas forming a star still has its entropy that decreases, such that:

$$\boxed{\Delta S_{\text{gas}} = S_{\text{gas},i} - S_{\text{gas},f} = 2Nk\log\left(\frac{V_i}{V_f}\right) > 0} \tag{12.2.34}$$

It is clear that the problem posed above is incomplete in the sense that the conditions imposed lead to the conclusion that the gas looses energy but how it does so and where the energy goes has not been specified. If we imagine our gas cloud to be surrounded by the vacuum of interstellar space, and given that we are assuming the cloud is gravitationally bound throughout (and hence cannot eject matter), it follows that the only means of loosing energy is via electromagnetic radiation. The second law of thermodynamics is preserved if this radiation carries off more entropy than the gas cloud looses. This is what we shall check in the following Section. Now we will derive the entropy of the radiation.

Since the gas is in internal thermodynamic equilibrium (by assumption - this being the condition for its temperature to be defined) it follows that the radiation emitted is black body radiation. In black body radiation the energy density is proportion to T^4 (see section Thermodynamics page 3713), i.e.:

$$\rho(T) = \sigma_{\text{S.B.}}T^4 \tag{12.2.35}$$

The entropy of a given volume V_r of radiation is found from the definition of the entropy itself (see section Thermodynamics page 3658):

$$\mathrm{d}S_{\text{radiation}} = \frac{\mathrm{d}Q}{T} \tag{12.2.36}$$

where $\mathrm{d}Q = V_r\mathrm{d}\rho(T)$.

Actually, the relation above is all that we shall require, but for completeness note that:

$$\mathrm{d}Q = V_r\mathrm{d}\rho(T) = V_r\cdot\mathrm{d}\left(\sigma_{\text{S.B.}}T^4\right) = 4\sigma_{\text{S.B.}}V_rT^3\mathrm{d}T \tag{12.2.37}$$

Hence:

$$S_{\text{radiation}}=\frac{\mathrm{d}Q}{T}=\int\frac{4\sigma_{\text{S.B.}}V_rT^3\mathrm{d}T}{T}=\int 4\sigma_{\text{S.B.}}V_rT^2\mathrm{d}T=\frac{4}{3}\sigma_{\text{S.B.}}V_rT^3 \tag{12.2.38}$$

Using:

$$\begin{cases}\mathrm{d}Q=V_r\mathrm{d}\rho(T) & \Rightarrow V_r=\dfrac{Q}{\rho(T)}\\ \rho(T)=\sigma_{\text{S.B.}}T^4 & \Rightarrow T^3=\dfrac{\rho(T)}{\sigma_{\text{S.B.}}T}\end{cases} \tag{12.2.39}$$

So finally:

$$S_{\text{radiation}}=\frac{4}{3}\sigma_{\text{S.B.}}V_rT^3=\frac{4}{3}\frac{Q}{T} \tag{12.2.40}$$

And this is the part of the entropy transported by the radiation! So to respect the second law of thermodynamics we have to assume that:

$$S_{\text{radiation}}\geq\Delta S_{\text{gas}} \tag{12.2.41}$$

Or explicitly:

$$\frac{4}{3}\frac{Q}{T}\geq 2nk\log\left(\frac{V_i}{V_f}\right) \tag{12.2.42}$$

It is likely also that a part of the entropy is also embedded in the deformation of space-time itself. Again we are faced here to an empirical difficulty as we don't have yet in this early 121st century (holocene calendar) the capacity to isolate a cloud of gas, observe its collapsing and measure directly its entropy variation...

12.2.1.1.2 Nuclear Duration Life

Once again remember that we have proved in the section of Classical Mechanics that inside a massive body the gravitational potential energy was given by (see page 3351):

$$E_p=-\frac{3}{5}\frac{GM^2}{R} \tag{12.2.43}$$

What has this have to do with starshine?

Well, notice that as R gets smaller, E_p gets more negative then energy is being converted to other forms, like heat. If a star can radiate this heat into space, then gravitational contraction might produce the luminosity of the star.

How much of this gravitational energy can be radiated away?

Remember that we know the radiation is related to heat (see section Statistical Mechanics page 3704) that is itself related to velocity (see section Continuum Mechanics page 3897), and that we proved during our study of the virial theorem (see section Continuum Mechanics page 3897) that:

$$E_c=-\frac{1}{2}E_p \tag{12.2.44}$$

Let us go back to our contracting Sun (actually a G2V-type star, aka yellow dwarf) problem! The virial theorem says that half the change in gravitational energy stays with the star (it heats the star through the atomic agitation). The other half is radiated away.

So, let's say that the Sun has been contracting and was originally much, much bigger. Initially its gravitational potential energy was tiny (why?), so the change in gravitational energy is:

$$\Delta E_p = E_{p,\text{init}} - E_{p,\text{now}} = 0 - \left(-\frac{3}{5}\frac{GM_\odot^2}{R_\odot}\right) = \frac{3}{5}\frac{GM_\odot^2}{R_\odot} \tag{12.2.45}$$

Now, half of this energy could have been radiated as the Sun shrank:

$$\boxed{E_{\text{rad}} = \frac{3}{10}\frac{GM_\odot^2}{R_\odot}} \tag{12.2.46}$$

that gives with our Sun the value: $\cong 10^{41}\,[\text{J}]$. That's a lot of energy! So how long could it sustain the luminosity of the Sun? The answer is obviously simply given by the ratio (it's just a dimensional analysis ratio):

$$\boxed{t_{KH} = \frac{E_{\text{rad}}}{L_\odot}} \tag{12.2.47}$$

This time is named the "Kelvin-Helmholtz timescale" and with the values of the Sun it gives:

$$t_{KH} = \frac{E_{\text{rad}}}{L_\odot} \cong \frac{10^{41}}{4\cdot 10^{26}} = 2.5\cdot 10^{14}\,[\text{s}] \cong 8\cdot 10^{6}\,[\text{years}] \tag{12.2.48}$$

and as we see the value is quite problematic... as our Earth would be older than our Sun! This problem comes from the fact that we don't take into account the fuel of stars that is the nuclear fusion. So let us see a little bit more accurate model now!

So the age of the stars is as we will see just now mainly a problem of calculation of nuclear fuel. The resolution of this problem was given by relativity, and in particular by the mass-energy equivalence (see section Special Relativity page 5679).

Even if the detailed description of nuclear reactions in the heart of the Sun was made in the mid-11930s (holocene calendar) by Hans Bethe, astrophysicists have suspected soon after Albert Einstein's work that the mass-energy equivalence could explain the brightness of the Sun on billions of years, for example through the fusion of ionized hydrogen (proton p) into ionized helium (two protons, two neutrons) via a series of steps (the specified energy is the kinetic energy of the different elements):

$${}^1_1\text{H} + {}^1_1\text{H} \rightarrow {}^2_1\text{H} + e^+ + 0.42\,[\text{MeV}] \tag{12.2.49}$$

The positron annihilates instantly with one of the electrons of a surrounding hydrogen and their mass-energy is liberated in the form of two gamma photons:

$$e^+ + e^- \rightarrow 2\gamma + 1.20\,[\text{MeV}] \tag{12.2.50}$$

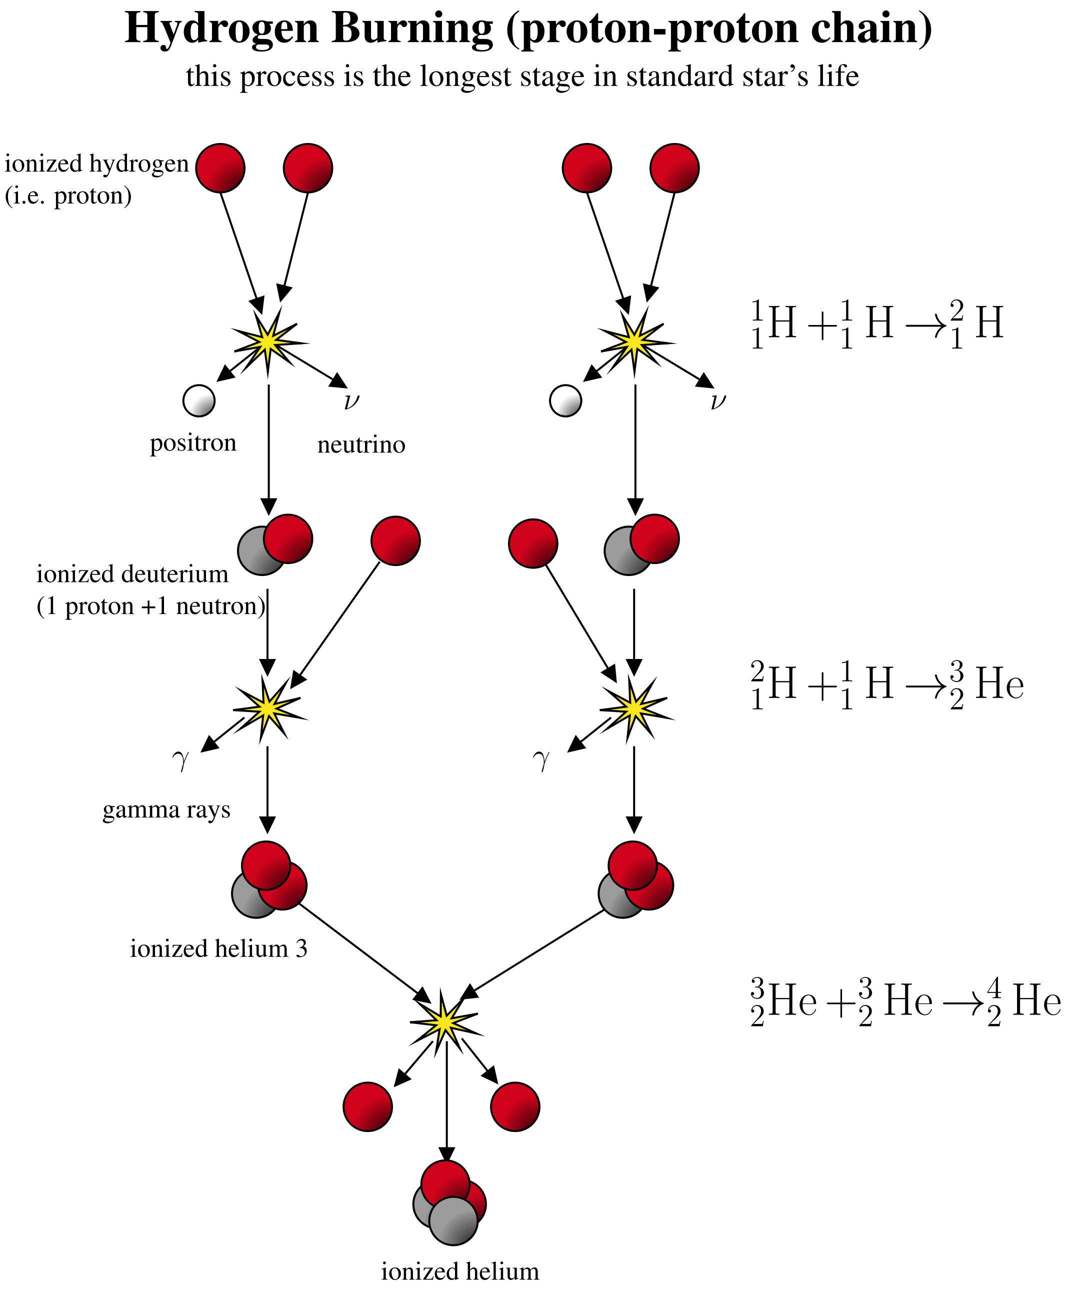
After this the deuterium produced in the first stage can fuse with another hydrogen nucleus to produce an isotope of helium:

$${}^2_1\text{H} + {}^1_1\text{H} \rightarrow {}^3_2\text{He} + \gamma + 5.49\,[\text{MeV}] \tag{12.2.51}$$

Finally, two isotopes of helium ^{3}He may fuse and produce the normal isotope of helium $^{3}{}_{2}\text{He}$ and also two hydrogen nuclei that can start again the reaction in three difference ways named PPI (dominant at temperatures of 10 to 14 millions Kelvins), PPII (dominant at temperatures of 14 to 23 millions Kelvins) and PPIII (dominant above 23 millions Kelvins):

$$ {}^3_2\text{He}+{}^3_2\text{He}\rightarrow{}^4_2\text{He}+{}^1_1\text{He}+{}^1_1\text{He}+12.86\,[\text{MeV}] \tag{12.2.52} $$

And these reactions do not occur all with the same probability and at the same temperatures...



Hydrogen Burning (proton-proton chain)
this process is the longest stage in standard star's life
ionized hydrogen
(i.e. proton)
positron
neutrino
ν
ν
${}^1_1\text{H}+{}^1_1\text{H}\rightarrow{}^2_1\text{H}$
ionized deuterium
(1 proton +1 neutron)
γ
γ
gamma rays
${}^2_1\text{H}+{}^1_1\text{H}\rightarrow{}^3_2\text{He}$
ionized helium 3
${}^3_2\text{He}+{}^3_2\text{He}\rightarrow{}^4_2\text{He}$
ionized helium

Figure 12.160: **Diagram of the proton-proton chain reaction in typical Sun size stars**

The measurement of the mass of the proton gives $m_p \cong 1.673\cdot 10^{-27}$ [kg], while the helium mass is $m_{\text{He}} \cong 6.645\cdot 10^{-27}$ [kg], that is to say a loss in atomic mass (we neglect the mass of positrons which is $10,000$ times smaller than that of the neutrino):

$$ 4m_p - m_{\text{He}} \cong 0.047\cdot 10^{-27}\,[\text{kg}] \tag{12.2.53} $$

So a relative loss of mass by fusion (this is the part of the reactions that escapes from the Sun in the form of kinetic energy):

$$\frac{\Delta m}{m}=\frac{0.047\cdot 10^{-27}}{4\cdot 1.673\cdot 10^{-27}}\cong 0.0072=0.72\% \tag{12.2.54}$$

We will prove further below that the Sun emits a power output of:

$$P_{\odot}\cong 3.861\cdot 10^{26}\,[\text{W}] \tag{12.2.55}$$

Therefore its mass consumption per second is:

$$\frac{\Delta m}{t}=\frac{E}{tc^2}=\frac{P_{\odot}}{c^2}\cong 4.4\cdot 10^{9}\,[\text{kg}\cdot\text{s}^{-1}] \tag{12.2.56}$$

i.e. its mass decreases by 4.4 million tonnes per second...

Now we know that this value corresponds to only 0.72% of the mass put in reaction in a fusion. The total mass reacted is then (rule of three):

$$\frac{4.4\cdot 10^{9}}{0.0072}\cong 6.27\cdot 10^{11}\,[\text{kg}\cdot\text{s}^{-1}] \tag{12.2.57}$$

Thus, at every second 627 million tons of hydrogen 1(ionized) fuse into helium 4 with a weight loss of 4.4 million tonnes which is converted into energy.

Assuming that only the center of the Sun fills the thermal conditions for the fusion ($\cong 10\%$ of its total mass), this brings us to determine the time of nuclear life of the Sun (or any other Star of the same type whose mass is known):

$$t_{\text{nucl}}=\frac{0.1M_{\odot}}{6.27\cdot 10^{11}}\cong 3.17\cdot 10^{17}\,[\text{s}] \tag{12.2.58}$$

Transforming this in years we have:

$$t_{\text{nucl}}\cong 1.01\cdot 10^{10}\,[\text{years}] \tag{12.2.59}$$

As we know that Earth is almost 4.5 billion years that gives us an indication that the Sun has very likely already made more than half of its lifespan.

If we apply the same calculations to the next step of our Sun, we get once all Hydrogen consumed transformed into Helium (at a temperature of 10 millions degrees to counterbalance gravity as we will prove it further below) a few million years before the next step. Then almost all Helium will be transformed into Carbon (as the pressure and therefore temperature increase to almso 200 million degrees to counterbalance gravity) and this state last only a few hundred thousands years before the next step. Then almost all Carbon will be transformed into Neon and this state last only a few thousands years before the next step. Then almost all Neon will be transformed into Oxygen and this state last only a few years before the next step. Then almost all Oxygen will be transformed into Silicon and this state last only a few months before the next step. Then almost all Silicon will be transformed into Nickel (at a temperature of 2.5 billion degrees) and this state last only a few weeks before the next step. As Nickel decays into Iron (one of the most stable elements) afterwards it can happen that the stars collapse into a neutron star, or even a quark star or in some cases in a Black Hole.

12.2.1.1.3 Internal Temperature

The stars are assumed to be spherical clusters of hydrogen gas where the interactions between molecules are governed by the gravitational attraction.

A star has no wall that delimits it, that is to say that there are no external forces coming from vacuum and therefore:

$$PV = 0 \tag{12.2.60}$$

and also not any bulk modulus.

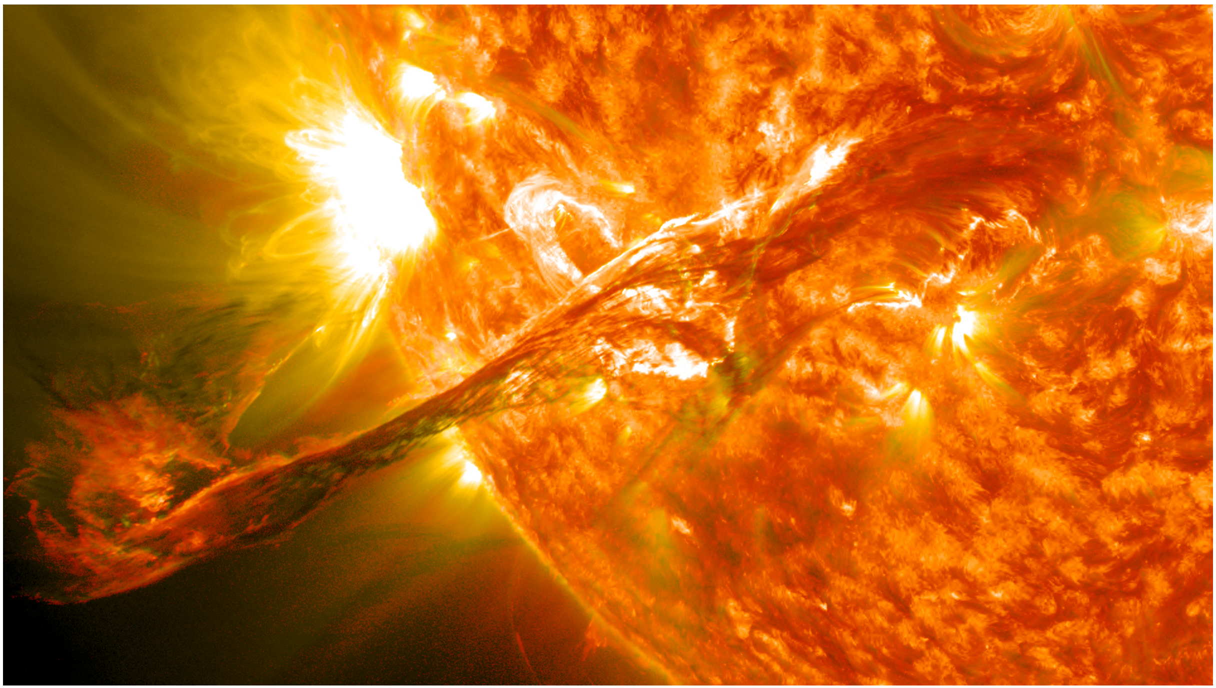


Figure 12.161: **Sun Corona zoom (source: NASA Goddard Space Flight Center)**

Remark

A solar flare is an intense localized eruption of electromagnetic radiation in the Sun's atmosphere that occur in active regions and are often, but not always, accompanied by coronal mass ejections, solar particle events, and other solar phenomena. The occurrence of solar flares varies with the actual 11-year solar cycle. Solar flares are thought to occur when stored magnetic energy in the Sun's atmosphere accelerates charged particles in the surrounding plasma. This results in the emission of electromagnetic radiation across the electromagnetic spectrum. High-energy electromagnetic radiation from solar flares is absorbed by the daylight side of Earth's upper atmosphere, in particular the ionosphere, and does not reach the surface most of the time. This absorption can temporarily increase the ionization of the ionosphere which may interfere with short-wave radio communication. The prediction of solar flares is an active area of research. Solar flares occur in a power-law spectrum of magnitudes; an energy release of typically 10^{20} joules of energy suffices to produce a clearly observable event, while a major event can emit up to 10^{25} joules (estimated value of the Carrington event that has occurred in 11859 according to holocene calendar).

The National Oceanic and Atmospheric Administration ranks geomagnetic storms on a scale running from G1, causing an increase in auroral activity and minor fluctuations in power supplies, up to G5, which includes extreme cases like the Carrington event. Even a G2 event is capable of causing damages, as when SpaceX lost 40 satellites in Feb 2022 when a G2 storm prevented them reaching their intended altitude. According to [353] speculation and worst case scenario, extreme solar flares from our Sun (actually a G2V-type star, aka yellow dwarf) to an upper limit of 10^{28} joules (with a frequency of 26 million years to occur) may even lead to mass extinction event mainly because of the subsequent ozone layer depletion.

Scale	Description	Effect	Physical measure	Average Frequency (1 cycle $=11$ years)
G 5	**Extreme**	**Power systems:** Widespread voltage control problems and protective system problems can occur, some grid systems may experience complete collapse or blackouts. Transformers may experience damage. **Spacecraft operations:** May experience extensive surface charging, problems with orientation, uplink/downlink and tracking satellites. **Other systems:** Pipeline currents can reach hundreds of amps, HF (high frequency) radio propagation may be impossible in many areas for one to two days, satellite navigation may be degraded for days, low-frequency radio navigation can be out for hours, and aurora has been seen as low as Florida and southern Texas (typically 40° geomagnetic lat.).	$Kp=9$	4 per cycle (4 days per cycle)
G 4	**Severe**	**Power systems:** Possible widespread voltage control problems and some protective systems will mistakenly trip out key assets from the grid. **Spacecraft operations:** May experience surface charging and tracking problems, corrections may be needed for orientation problems. **Other systems:** Induced pipeline currents affect preventive measures, HF radio propagation sporadic, satellite navigation degraded for hours, low-frequency radio navigation disrupted, and aurora has been seen as low as Alabama and northern California (typically 45° geomagnetic lat.).	Kp $=8$, including a 9 -	100 per cycle (60 days per cycle)
G 3	**Strong**	**Power systems:** Voltage corrections may be required, false alarms triggered on some protection devices. **Spacecraft operations:** Surface charging may occur on satellite components, drag may increase on low-Earth-orbit satellites, and corrections may be needed for orientation problems. **Other systems:** Intermittent satellite navigation and low-frequency radio navigation problems may occur, HF radio may be intermittent, and aurora has been seen as low as Illinois and Oregon (typically 50° geomagnetic lat.).	$Kp=7$	200 per cycle (130 days per cycle)
G 2	**Moderate**	**Power systems:** High-latitude power systems may experience voltage alarms, long-duration storms may cause transformer damage. **Spacecraft operations:** Corrective actions to orientation may be required by ground control; possible changes in drag affect orbit predictions. **Other systems:** HF radio propagation can fade at higher latitudes, and aurora has been seen as low as New York and Idaho (typically 55° geomagnetic lat.).	$Kp=6$	600 per cycle (360 days per cycle)
G 1	**Minor**	**Power systems:** Weak power grid fluctuations can occur. **Spacecraft operations:** Minor impact on satellite operations possible. **Other systems:** Migratory animals are affected at this and higher levels; aurora is commonly visible at high latitudes (northern Michigan and Maine).	$Kp=5$	1700 per cycle (900 days per cycle)

Table 12.15: **Solar flares Geomagnetic scale (source: NOAA)**

Based on the return on experience of the G5 Carrington event and the Canada 11989 (holocene calendar) G5 event (the "Miyake event[a]" can't be used as 1400 years ago electric devices didn't exist), it's very unlikely that a even a super solar flare may damage HDD ans SSD drive. First because HDD drives already have magnets to make them work that are much stronger than G5 solar flares and SSD drive are said to be almost immune to magnetic fields. Instead, super solar flares can generate very high electrical currents in long conductors (i.e. long power grids), like power lines. These electrical surges can damage hardware connected to the grid just like a lightning strike. So if you have a Solar flare tracking app and get a G5 alarm, then just disconnect all your electric devices from the outlet (you don't need to put them in a Faraday cage or run into a nuclear basement, that's very likely useless). Some people say that SSD's are even immune to power outage.

There is another common scale for solar flares:

Class	**Intensity** $[\mathrm{W}\cdot\mathrm{m}^{-2}]$	**Luminosity** $(\mathrm{L}_\odot, 100\ \mathrm{sec})$
B	10^{-7}	10^{-8}
C	10^{-6}	10^{-7}
M	10^{-5}	10^{-6}
X	10^{-4}	10^{-5}

Table 12.16: **Solar flares intensity scale**

An X2 is twice an X1. The 11989 (holocene calendar) event in Canada was a X7.3. The Carrington event was estimated X45 to X50.

---

[a] Miyake events are events several orders of magnitude greater than the Carrington event. Scientists think the most recent Miyake event was around 80 times more powerful than the Carrington event. We now know of 10 Miyake events over the past $15,000$ years. While they appear to be relatively infrequent, we don't know whether they occur with any sort of pattern or if they're predictable. It is also unclear yet what changes the Sun undergoes to produce them.

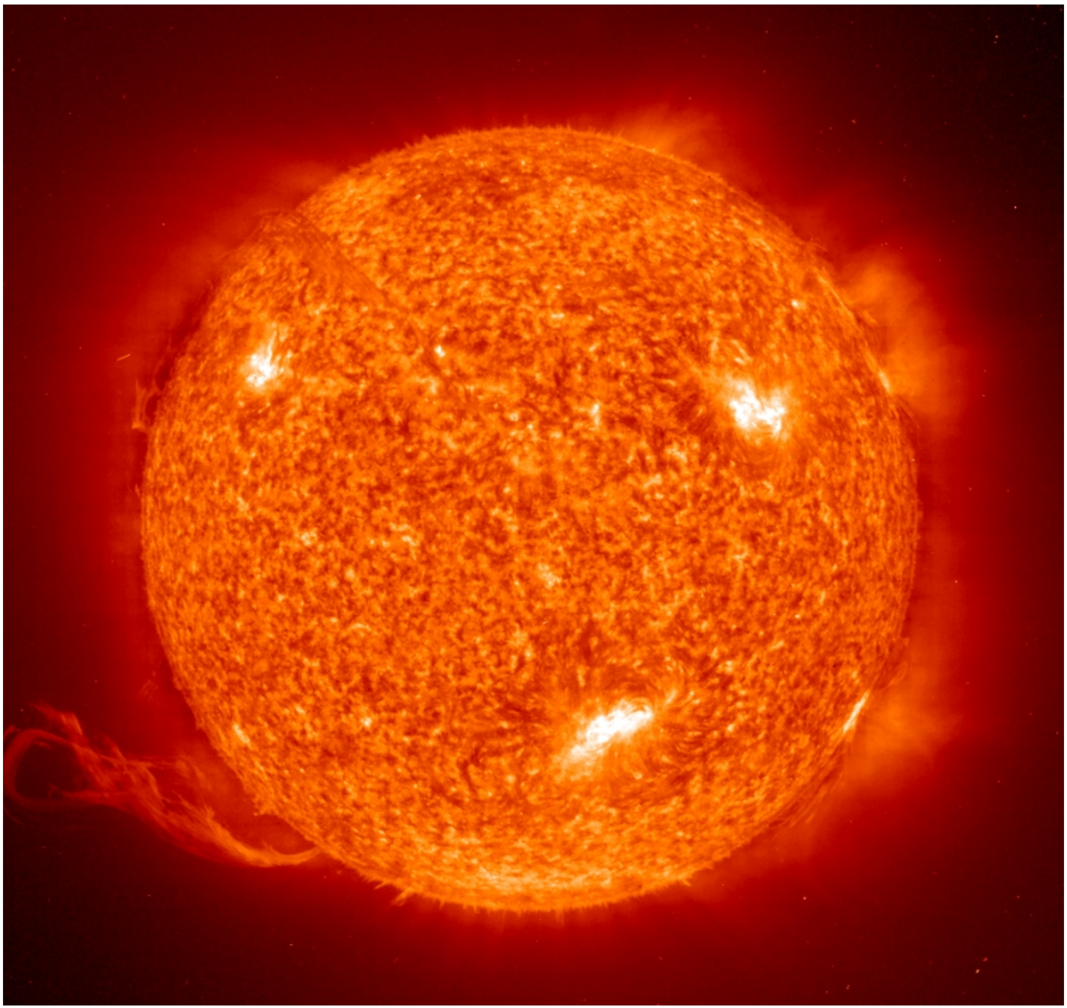

Figure 12.162: **Global Sun overview (source: NASA)**

Using the virial theorem proven in the section of Continuum Mechanics (see page 3897) that gives us:

$$E_c=-\frac{1}{2}E_p \qquad (12.2.61)$$

we have for a homogeneous spherical gas of radius R and mass M composed of N bodies, the following relations proved for the first one in the section of Continuum Mechanics (see page 3902) of the second in the section of Classical Mechanics (see page 3356):

$$E_c=\frac{3}{2}kNT \quad \text{and} \quad E_p=-\frac{3}{5}\frac{GM^2}{R} \qquad (12.2.62)$$

Therefore:

$$\frac{3}{2}kNT=-\frac{1}{2}\left(-\frac{3}{5}\frac{GM^2}{R}\right) \tag{12.2.63}$$

where for recall k is the Boltzmann constant.

Which gives:

$$T=\frac{1}{5}\frac{GM^2}{NkR} \tag{12.2.64}$$

in order to not make the confusion between to constant of ideal gas denoted R and the radius it is more convenient to write the latter relation as (and making the Boltzmann constant more explicit):

$$\boxed{T=\frac{1}{5}\frac{GM^2}{nk_Br}} \tag{12.2.65}$$

With for a given star N being the ratio of the total mass of the star on the average mass of a molecule.

For the Sun (actually a G2V-type star, aka yellow dwarf) it comes that $T\cong 10^7$ [K] (i.e. 10 millions degrees).

This is the central temperature of the Sun. Optical measurements measured from Earth only give the surface temperature (chromosphere), thus $6,000$ [K]. The calculated internal temperature is about $1,600$ times higher than at the surface. Independent methods based on nuclear reactions in the center of the Sun (measurement of solar neutrino flux) give the same order of magnitude, but the precise values differ by a factor of 2-3.

Layer	Part	Temperature [K]
Inner Layers	Core	$15,000,000$
	Radiative zone	$7,000,000$
	Convection zone	$2,000,000$
Outer Layers	Photosphere	$4,000$-$6,500$
	Chromosphere	$4,000$-$8,000$
	Transition region	$8,000$-$500,000$
	Corona	$500,000$-$1,000,000$

Figure 12.163: **Kelvin-Helmholtz instability on the Sun observed using the NSF Daniel K. Inouye Solar Telescope in Maui, Hawaii in 12026**

Let us now see how good we can estimate the external temperature!

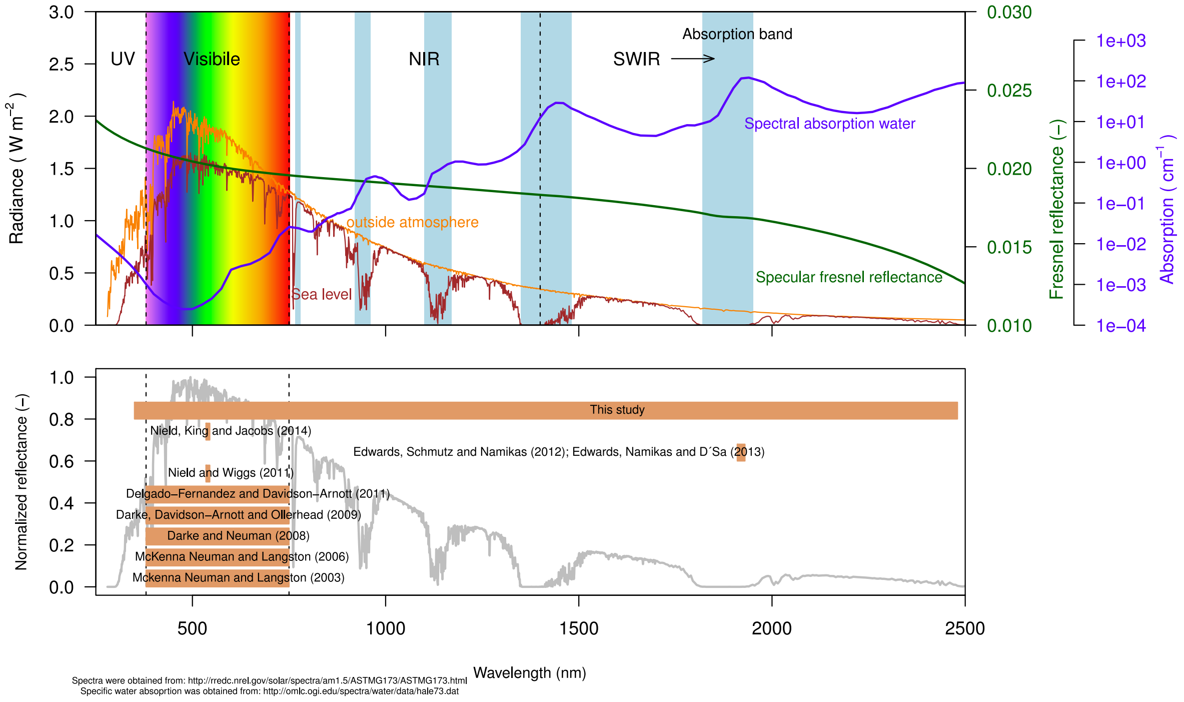
12.2.1.1.4 External Temperature

We observe and measure the black body spectrum of our Sun as having actually a peak of emission at: 490 [nm]. Therefore using Wien's Displacement law (see section Mechanics page 3727):

$$T=\frac{2,897.8\cdot 10^{-6}\,[\text{mK}]}{\lambda_{\text{max}}}=\frac{2,897.8\cdot 10^{-6}\,[\text{mK}]}{490\cdot 10^{-9}\,[\text{m}]}=5,900\,[\text{K}] \qquad (12.2.66)$$

A very basic situation is to calculate the rate at which the Sun heats the atmosphere at sunrise (a better denomination is "at daybreak").

Below the reader can see a plot of the spectral power distribution of sunlight (in $[\text{W}\cdot\text{m}^{-2}]$ outside the atmosphere (yellow line) and at sea level (brown line), to illustrate the effect of absorption of sunlight by water (see [418]). Included in the top panel: spectral Fresnel reflectance for a water surface (green line) and absorption coefficients (in $[\text{cm}^{-1}]$ for pure water (blue line). Bottom panel: overview of the studies (including this study) that demonstrate the potential of relating reflectance to surface moisture. The orange bars indicate the spectral range in which the measurements were taken.



Spectra were obtained from: http://rredc.nrel.gov/solar/spectra/am1.5/ASTMG173/ASTMG173.html
Specific water absoprtion was obtained from: http://omlc.ogi.edu/spectra/water/data/hale73.dat

Figure 12.164: Spectral power distribution of sunlight (source: [418])

Remark

Spectra were obtained from:

http://irredc.nrel.govisolar/spectra/am1.5/ASTMG173/ASTMG173.html

Specific water absorption were obtained from:

http://omlc.ogi.edu/spectra/water/data/hale73.dat

Now that we have the approximate temperature of our Sun, we can use the Stefan-Boltzmann law to get the energy emitted (see section Thermodynamics page 3706):

$$M(T)=\frac{2\pi^5k^4}{15c^2h^3}T^4=\sigma T^4 \tag{12.2.67}$$

with:

$$\sigma\cong\frac{2\pi^5k^4}{15c^2h^3}=\frac{\pi^2k^4}{60c^2\hbar^2}=5.67051\cdot 10^{-8}\left[\mathrm{W}\cdot\mathrm{m}^{-2}\cdot\mathrm{K}^4\right] \tag{12.2.68}$$

Therefore we get for the Sun:

$$M(T)=\frac{2\pi^5k^4}{15c^2h^3}T^4\cong 6.87\cdot 10^7\;[\mathrm{W}\cdot\mathrm{m}^{-2}] \tag{12.2.69}$$

Knowing the average distance from the Sun (actually a G2V-type star, aka yellow dwarf) to be about $1.496\cdot 10^{11}$ [m] $=1$ [UA] (Astronomical Unit), we can calculate the surface of the sphere at $R=1$ [UA] and thus the solar power P. Therefore:

$$S=4\pi R^2\cong 2.812\cdot 10^{23}\;[\mathrm{m}^2] \tag{12.2.70}$$

and:

$$P_{\odot}=S\cdot M(T)\cong 3.861\cdot 10^{26}\,[\mathrm{W}] \tag{12.2.71}$$

Remark

From $P_{\odot}=S\cdot M(T)\cong 3.861\cdot 10^{26}\,[\mathrm{W}]$ we can calculate the actual Solar flux (i.e. Sun flux) - or "peak Sun hours" - on Earth assuming that the latter is at an average distance of $149.09\cdot 10^{9}\,[\mathrm{m}]$ of the Sun:

$$\Phi_{\odot}=\frac{P_{\odot}}{4\pi R^2}=\frac{3.861\cdot 10^{26}}{4\pi(149.09\cdot 10^{9})^2}\cong 1,382\,[\mathrm{W}\cdot\mathrm{m}^{-2}]$$

The average emittance also named "average bolometric emittance" received by the Earth outside the atmosphere, also named "solar constant" (which is in fact not constant ... on a scale of several billion years), is directly measurable in orbit and is equal to $\sim 1,373\,[\mathrm{W}\cdot\mathrm{m}^{-2}]$.

Assuming an albedo for Earth of $\rho\cong 0.31$ (but there is considerable variation in this value over the surface of the Earth and over time as well), then:

$$\Phi_{\rho}=(1-\rho)\cdot 1,382\cong 953\,[\mathrm{W}\cdot\mathrm{m}^{-2}]$$

However the Earth isn't all the time facing the same part of its surface to the Sun. Assuming that only a third of a 24 hours days is facing the Sun, then:

$$\bar{\Phi}_{\rho}=\frac{1}{3}\cdot 1,382\cong 318\,[\mathrm{W}\cdot\mathrm{m}^{-2}]$$

Assuming known the radius of the Sun as being $r_{\odot}\cong 6.9599\cdot 10^{8}$ [m], we can calculate its surface S and its solar radiative emittance $M_{\odot}(T)$. So:

$$S_{\odot}=4\pi r_{\odot}^2\cong 6.087\cdot 10^{18}\,[\mathrm{m}^2] \tag{12.2.72}$$

and:

$$M_{\odot}(T)=\frac{P_{\odot}}{S_{\odot}}\cong 6.343\cdot 10^{7}\,[\mathrm{W}\cdot\mathrm{m}^{-2}] \tag{12.2.73}$$

Remark

The radiating surface of a star is named "photosphere". Indeed, as stars, excepting neutron stars, have no solid surface, the photosphere is typically used to describe the Sun's or another star's visual surface.

Using the Stefan-Boltzmann law (see section Statistical Mechanics page 3706), we can now calculate approximately the thermodynamic temperature of the photosphere:

$$T=\sqrt[4]{\frac{M_{\odot}(T)}{\sigma}}\cong 5,780\,[\mathrm{K}] \tag{12.2.74}$$

which is very accurate to direct measurement!!! More generally the previous relation is written:

$$T=\sqrt[4]{\frac{P_{\odot}(T)}{4\pi r_{\odot}^2\sigma}} \tag{12.2.75}$$

or respecting the notation of optical geometry:

$$\boxed{T=\sqrt[4]{\frac{L_\odot(T)}{4\pi r_\odot^2\sigma}}} \tag{12.2.76}$$

So since we can estimate the luminosity and the temperature of a star (or something that looks like...) we can also estimate it's radius!

Figure 12.165: **Layer's view of our Sun (source: NASA)**

Planck's law (see section Thermodynamics page 3719) applied at this temperature allow us to calculate the spectral distribution of solar radiation and then we see that the maximum of the intensity is in the visible range (our visible range!!!) spectrum which is from 400 [nm] to 700 [nm].

Obviously the reader has to keep in mind that the temperature of a star is an information that doesn't make really sense (we should speak instead of "average temperature", i.e. an integral of the spectrum function as we know it!) as the temperature depends on the wavelength. As provided by the paper [86], we can see the temperature of our Sun (actually a G2V-type star, aka yellow dwarf) in function of the wavelength here below as measured in the 12008-08-24 according to the holocene calendar (the lower figure is just a zoom on the visible spectrum):

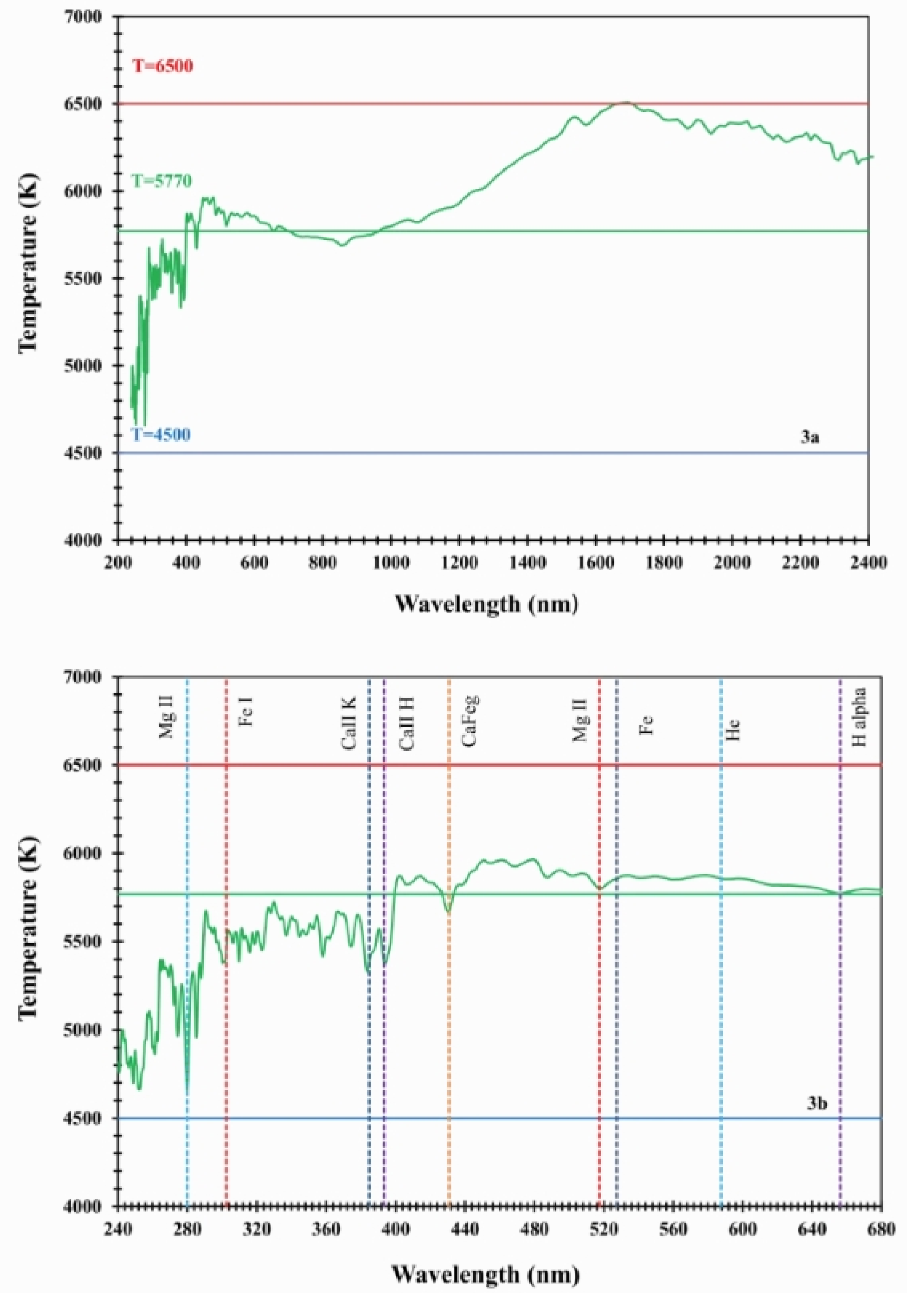

Figure 12.166: **Sun temperature in function of wavelength the 12008-08-24**

And in the same paper we can see the evolution of our Sun's temperature for 17 years (daily average) on the H_α wavelength (656.2 [nm]):

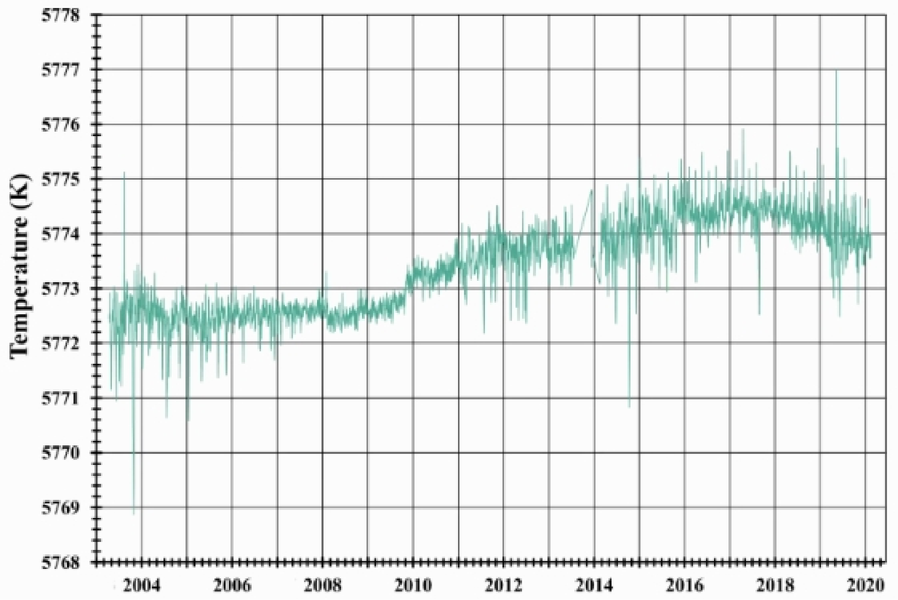

Figure 12.167: Sun temperature in function of time

In the above plot the years are given based on the Gregorian calendar.

In the figure below, we can see an extrapolation of mean surface temperatures on Earth taking into account the slow increase of the insolation due to the aging of the Sun (a mean increase of $\sim 0.33\,[\mu\mathrm{W}\cdot\mathrm{m}^{-2}]$). Simulations where performed with a tridimensional global climate model described in Leconte et al. (2013; `https://ui.adsabs.harvard.edu/abs/2013Natur.504..268L/abstract`). When the average insolation received by the Earth reaches $375\,[\mathrm{W}\cdot\mathrm{m}^{-2}]$ (about 1 billion years from now), the greenhouse effect of water vapor enters a runaway regime that causes the total evaporation of the oceans. Temperatures above that threshold are very uncertain but could be greater than $1,000\,[^\circ\mathrm{C}]$.

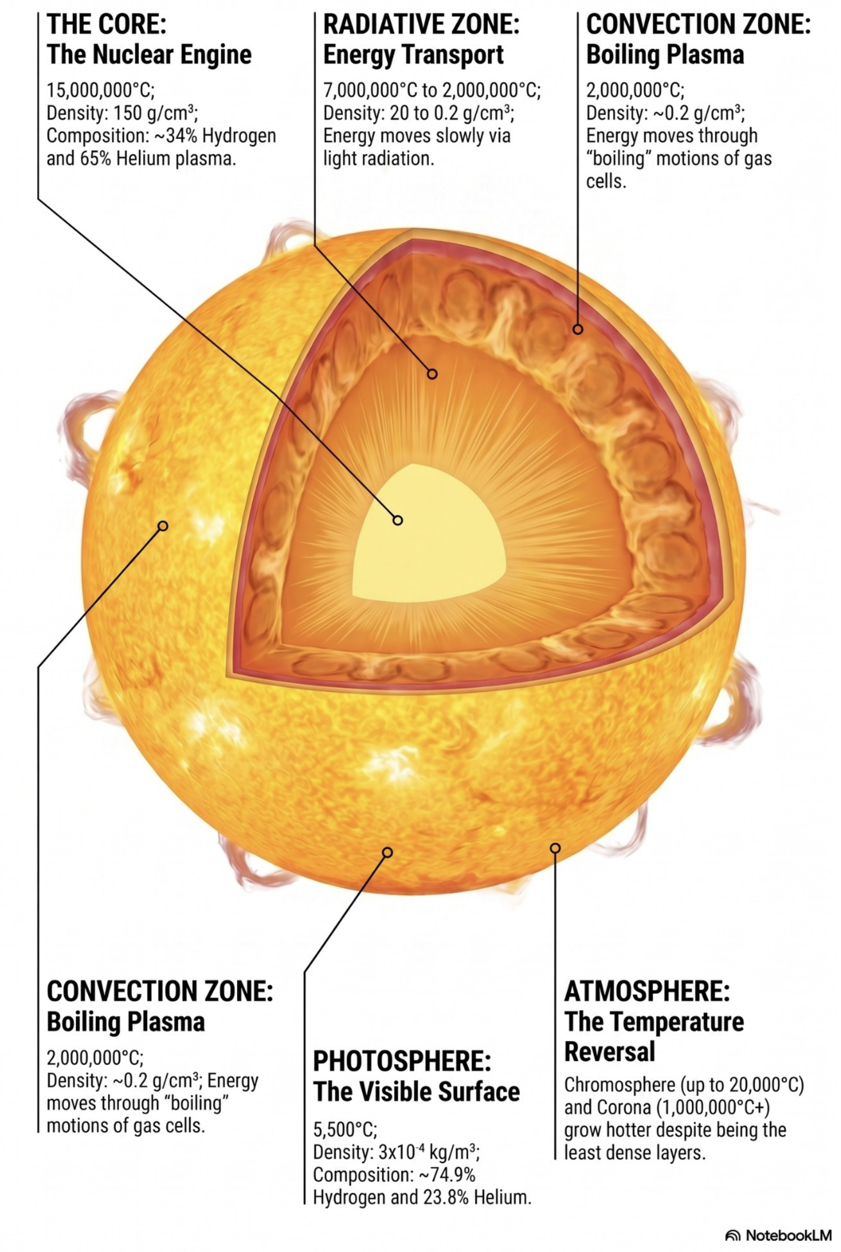
Figure 12.168: Numerical simulations of the surface temperature of the Earth at the spring equinox exposed to an increasingly bright Sun in the future.

So life will very likely disappear on Earth a veeeeery long time before the Sun (actually a

G2V-type star, aka yellow dwarf) turns into a supernova....

Remark

For information, the rotation of Earth's on itself slows down at the day we write these lines of approximately 2.3 milliseconds per century. That means 1 hour every 180 millions years. Each year the Earth's orbit speed around the Sun also slows down of approximately 3 nanometers-per-second. Using Kepler's law, that means that the Earth goes further away from the Sun of 3 micrometers per 1 billion year......!!!!



THE CORE:

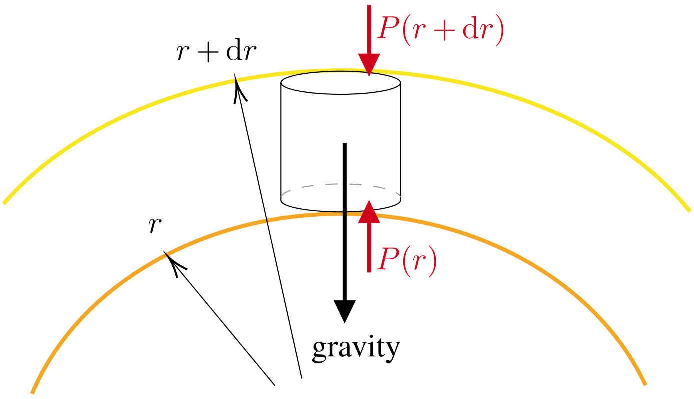
12.2.1.1.5 Equation of Hydrostatic Equilibrium

The absence of changes in most stars over timescales of hours or days indicates that the forces acting on the matter in the stars are essentially perfectly balanced (remember figure showed earlier above). Here we analyse this constraint in more detail.

In the figure below we have represented a piece mass shell in a spherically symmetric star where we consider in reality a very small cylindrical element between radius r and radius $r+\mathrm{d}r$ hence the fact that the element surface dS is considered as being the same (but we can neglect the pressure variation as it can be very big even in a small height difference):



If we denote by $M(r)$ the mass of star in the smaller radii and Δm the mass in the cylinder, we get:

$$F_g=-\frac{GM(r)\Delta m}{r^2} \tag{12.2.77}$$

Now for the pressure we have (net force due to difference in pressure between upper and lower faces):

$$F_P=P(r)\mathrm{d}S-P(r+\mathrm{d}r)\mathrm{d}S \tag{12.2.78}$$

Using the definition of the derivative but applied to the pressure:

$$\frac{P(r+\mathrm{d}r)-P(r)}{\mathrm{d}r}=\frac{\mathrm{d}P}{\mathrm{d}r}\Leftrightarrow P(r+\mathrm{d}r)=P(r)+\frac{\mathrm{d}P}{\mathrm{d}r}\mathrm{d}r \tag{12.2.79}$$

Therefore:

$$F_P=P(r)\mathrm{d}S-P(r+\mathrm{d}r)\mathrm{d}S=P(r)\mathrm{d}S-\left(P(r)+\frac{\mathrm{d}P}{\mathrm{d}r}\mathrm{d}r\right)\mathrm{d}S=-\frac{\mathrm{d}P}{\mathrm{d}r}\mathrm{d}r\mathrm{d}S \tag{12.2.80}$$

Now we have as mass element that is given as we know by:

$$\Delta m=\rho\mathrm{d}r\mathrm{d}S \tag{12.2.81}$$

Applying Newton's second law to the cylinder:

$$F_G+F_P=-\frac{-GM(r)\Delta m}{r^2}-\frac{\mathrm{d}P}{\mathrm{d}r}\mathrm{d}r\mathrm{d}S \tag{12.2.82}$$

This sum must be equal to 0 everywhere if the star is indeed static. Therefore:

$$-\frac{-GM(r)\rho \mathrm{d}r\mathrm{d}S}{r^2}-\frac{\mathrm{d}P}{\mathrm{d}r}\mathrm{d}r\mathrm{d}S=0 \tag{12.2.83}$$

After simplification we get the "equation of hydrostatic equilibrium" or "stellar structure equation":

$$\boxed{\frac{\mathrm{d}P}{\mathrm{d}r}=-\frac{GM(r)}{r^2}\rho} \tag{12.2.84}$$

So far we already estimated roughly the core temperature of the Sun (actually a G2V-type star, aka yellow dwarf) and of the photosphere. Let us now first estimate roughly its average pressure:

$$\bar{P}_{\odot}=\frac{\bar{F}_{\odot}}{S_{\odot}}\cong\frac{GM_{\odot}^2}{R_{\odot}^2}4\pi R_{\odot}^2=\frac{GM_{\odot}^2}{4\pi R_{\odot}^4}\cong 10^{14}\,[\text{Pa}] \tag{12.2.85}$$

A better estimation is given by using the equation of hydrostatic equilibrium:

$$\frac{\mathrm{d}P}{\mathrm{d}r}=-\frac{GM(r)\rho}{r^2}=-\frac{G}{r^2}\left(\frac{4}{3}\pi r^3\rho\right)\rho=-\frac{4}{3}\pi G\rho^2 r \tag{12.2.86}$$

and integrate (assuming density is constant):

$$\int_0^R -\frac{4}{3}\pi G\rho^2 r\mathrm{d}r=-\frac{4}{3}\pi G\rho^2\frac{R^2}{2} \tag{12.2.87}$$

So we have an expression for the central pressure:

$$\boxed{P_{\odot}=\frac{2}{3}\pi G\rho^2 R^2=\frac{3}{2}\frac{GM_{\odot}^2}{\pi R^2}} \tag{12.2.88}$$

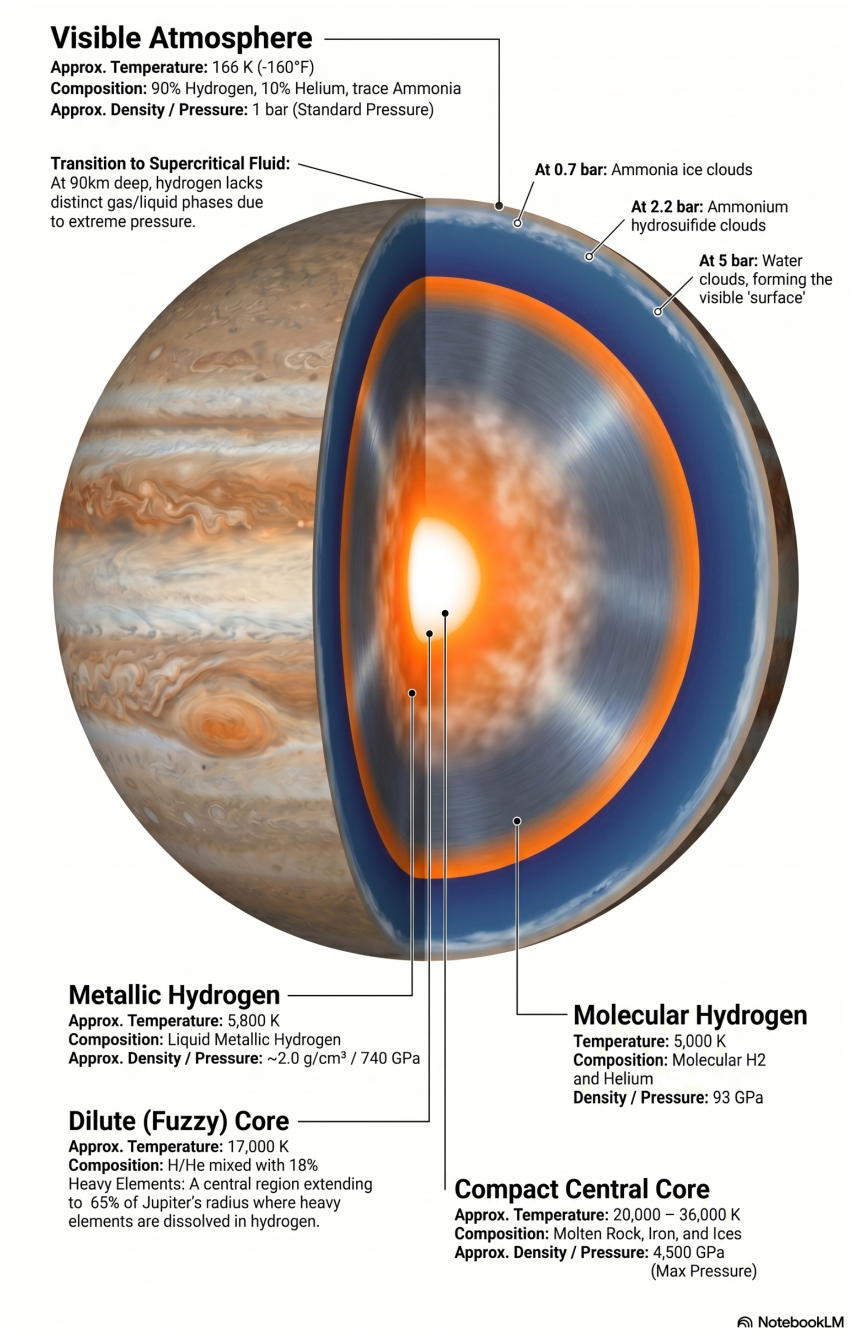
That is 6 times more than the previous roughly approximation and compared to direct measurement method this seems more accurate!

We also have for mean density of the Sun (actually a G2V-type star, aka yellow dwarf) :

$$\bar{\rho}_{\odot}=\frac{M_{\odot}}{V_{\odot}}=\frac{M_{\odot}}{\frac{4}{3}\pi R_{\odot}^3}=\frac{1.98855\cdot 10^{30}}{\frac{4}{3}\pi(6.9598\cdot 10^8)^3}\cong 1408.5\,[\text{kg}\cdot\text{m}^{-3}] \tag{12.2.89}$$

to compare with the density of pure water that is $1,000\,[\text{kg}\cdot\text{m}^{-3}]$ or to that of iron that is $7,874\,[\text{kg}\cdot\text{m}^{-3}]$. So we understand better why space image of the Sun looks like a big liquid sphere of gas as because of the gravity conditions the pressure is such that the gas is reduced to a density greater than that of water in average!!!!!

Here is a figure of what we think so far as comparison for Jupiter that is like a non-initiated star:



Visible Atmosphere
Approx. Temperature: 166 K (-160°F)
Composition: 90% Hydrogen, 10% Helium, trace Ammonia
Approx. Density / Pressure: 1 bar (Standard Pressure)
Transition to Supercritical Fluid: At 90km deep, hydrogen lacks distinct gas/liquid phases due to extreme pressure.
At 0.7 bar: Ammonia ice clouds
At 2.2 bar: Ammonium hydrosuifide clouds
At 5 bar: Water clouds, forming the visible 'surface'
Metallic Hydrogen
Approx. Temperature: 5,800 K
Composition: Liquid Metallic Hydrogen
Approx. Density / Pressure: ~2.0 g/cm³ / 740 GPa
Molecular Hydrogen
Temperature: 5,000 K
Composition: Molecular H2 and Helium
Density / Pressure: 93 GPa
Dilute (Fuzzy) Core
Approx. Temperature: 17,000 K
Composition: H/He mixed with 18% Heavy Elements: A central region extending to 65% of Jupiter's radius where heavy elements are dissolved in hydrogen.
Compact Central Core
Approx. Temperature: 20,000 – 36,000 K
Composition: Molten Rock, Iron, and Ices
Approx. Density / Pressure: 4,500 GPa (Max Pressure)
NotebookLM

Using the equation of hydrostatic equilibrium we can estimate roughly the density of the photosphere:

$$\rho(R_\odot) = -\frac{\Delta P}{\Delta r}\frac{r^2}{GM(r)} \cong \frac{\bar{P}_\odot}{R_\odot}\frac{R_\odot^2}{GM} = \frac{\bar{P}_\odot R}{GM} \cong 525\,[\mathrm{kg}\cdot\mathrm{m}^{-3}] \tag{12.2.90}$$

So it is obvious that the density of the Sun decreases continuously outward from the center. The visible surface of the Sun (i.e. the photosphere) is a very thin layer, only about 500 [km] thick as compared to the radius of the Sun. The density of the photosphere is very, very low, about $0.2 \cdot 10^{-4}\,[\mathrm{kg}\cdot\mathrm{m}^{-3}]$ as estimated by observations. Therefore the average density of the Sun can only be explained by the density of its core that is very high, about $160,000\,[\mathrm{kg}\cdot\mathrm{m}^{-3}]$, much higher than any material that we know.

12.2.1.1.6 Brightness

The "intrinsic bolometric brightness" of a star corresponds to the total power radiated in the entire electromagnetic spectrum in the direction of the observer expressed relatively to the total power radiated by the Sun. Assuming all stars spherical and isotropic, we can express it in solar units:

$$L_{\text{bol}}=\frac{P_{\text{star}}}{P_{\odot}} \tag{12.2.91}$$

The radiated power P is calculated, as we know, by multiplying the radiative emittance (Stefan-Boltzmann law) by the surface of the star:

$$P=M(T)S=\sigma T^4 4\pi r^2 \tag{12.2.92}$$

The intrinsic bolometric luminosity of a star is therefore proportional to the square of its radius and the fourth power of its surface temperature. Taking the Sun (actually a G2V-type star, aka yellow dwarf) as a reference, the constants are simplified. We can the write:

$$L_{\text{bol}}=\frac{P_{\text{star}}}{P_{\odot}}=\left(\frac{T}{T_{\odot}}\right)^4\left(\frac{r}{r_{\odot}}\right)^2=c^{te}T^4r^2 \tag{12.2.93}$$

with $r_{\odot}\cong 6.9559\cdot 10^8$ [m] and $T_{\odot}\cong 5,780$ [K] hence $c^{te}\cong 1.85\cdot 10^{-33}$ $[\text{K}^{-4}\cdot\text{m}^2]$.

In astrophysics, we also use a logarithmic scale to express the bolometric luminosity of a star: the "absolute magnitude M". This unit has an empirical origin that will be explained below.

Caution! Estimate the mass of a distant star or distant galaxy based solely on its luminosity compared to that of the Sun is very hazardous given the diversity of properties of stars (and the same applies to galaxies). So if you do something like this never forget to indicate (or to check if you read a paper) the margin error!!! Never forget that a scientific paper without margin error is always suspicious!

Notice that if we assume that Sun emits isotropically (nearly uniform in all directions). The fraction of photons that reaches Earth is the ratio of Earth's cross-sectional area to the surface area of a sphere centered on the Sun with radius equal to the Sun–Earth R_d distance:

$$N_{\text{photons}}=\frac{\pi R_{♁}^2}{4\pi R_d^2}=\frac{R_{♁}^2}{4R_d^2}\cong\frac{(6.37\cdot 10^6)^2}{4(1.496\cdot 10^{11})^2}\cong 4.54\cdot 10^{-18} \tag{12.2.94}$$

Keeping in mind that the photons intercepted by Earth include those absorbed or scattered in the atmosphere and those reaching the surface; the fraction above is purely geometric (photons that impinge on Earth's disk).

12.2.1.1.7 Shining (apparent brightness)

Perhaps the easiest measurement to make of a star is its apparent brightness. We are purposely being careful about our choice of words. When we say "apparent brightness", we mean how bright the star appears to a detector here on Earth.

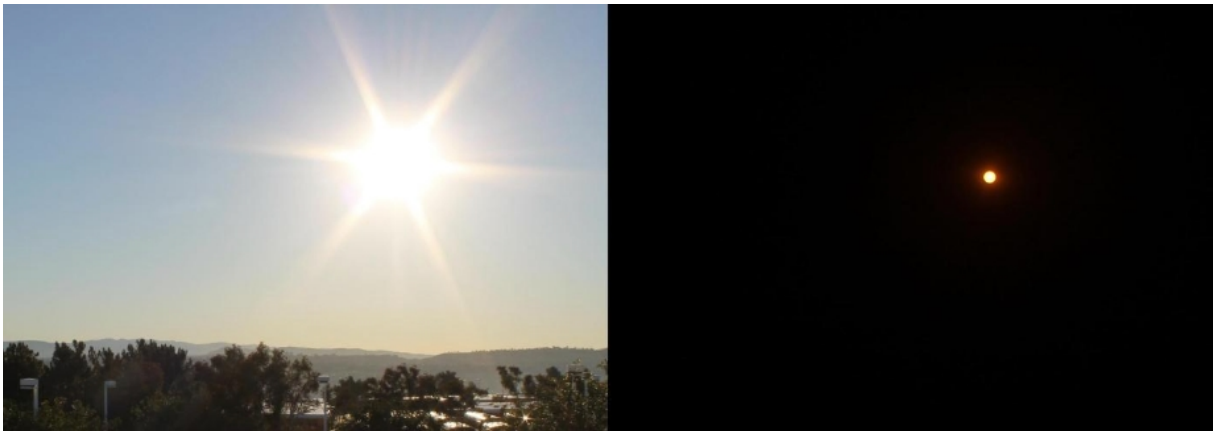


Figure 12.169: Sun appearance in a photograph with and without a solar filter (author: John Krieger)

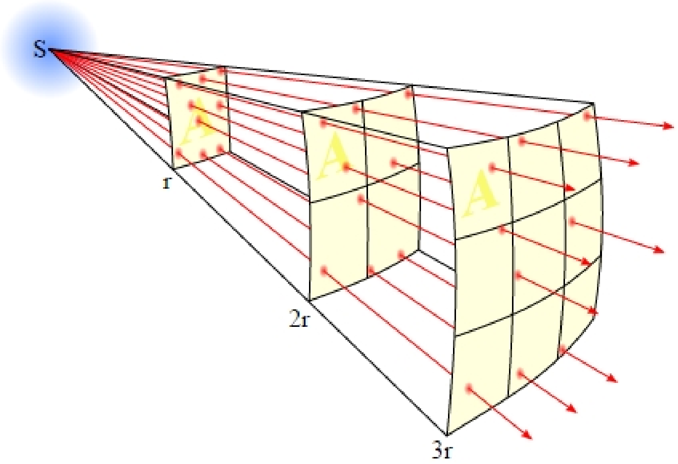
Definition (#12.2.538): The "brilliance" or "shining" or "apparent brightness" b of a star is the density of radiation received by the observer, that is to say equal to the flow of energy (power of the star at its surface) divided by the sphere surface with the radius equal to the distance which separates the observer from the star:

$$\boxed{b=\frac{P}{S}=\frac{P}{4\pi d^2}} \tag{12.2.95}$$

The brilliance decreases therefore with the square of the distance (as in myna other filed of physics):



✍**Example:**

A star has a known luminosity of $9.7 \cdot 10^{27}\,[\text{W}]$. Observations of the star show that the apparent brightness of light received on Earth from the star is $114\,[\text{nW} \cdot \text{m}^{-2}]$ (the human eye's sensitivity to light varies, but the minimum intensity of light detectable is approximately $0.1\,[\text{nW} \cdot \text{m}^{-2}]$).

Therefore:

$$b = \frac{P}{4\pi d^2} \Rightarrow d = \sqrt{\frac{P}{4\pi b}} = \sqrt{\frac{9.7 \cdot 10^{27}}{4\pi \cdot (114 \cdot 10^{-9})}} \cong 8.2 \cdot 10^{16}\,[\text{m}] \cong 8.67\,\text{light years} \tag{12.2.96}$$

It is important to notice that this quantity has no direct relation with the physical intrinsic properties of the respective star (unlike the bolometric brightness!).

Thus, two identical stars can have the same apparent brightness if (and only if) they lie at the same distance from Earth. However, as illustrated in Figure below, two different stars can appear equally bright if the more luminous one lies farther away. A bright star (that is, a star with large apparent brightness) is a powerful emitter of radiation, is near Earth, or both. A dim star is a weak emitter, is far from Earth, or both:

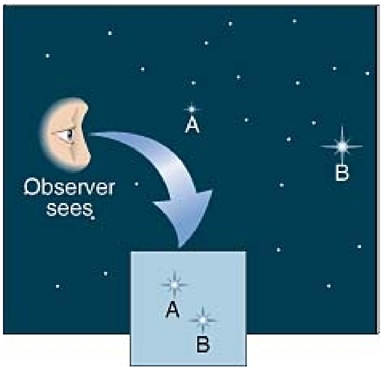


Figure 12.170: **Apparent luminosity**

The luminosity of a star, on the other hand, is the amount of light it emits from its surface. The difference between luminosity and apparent brightness depends on distance as we know now. Another way to look at these quantities is that the luminosity is an intrinsic property of the star, which means that everyone who has some means of measuring the luminosity of a star should find the same value. However, apparent brightness is not an intrinsic property of the star; it depends on your location. So everyone will measure a different apparent brightness for the same star if they are all different distances away from that star.

Apparent brightness is the brightness perceived by an observer on Earth and absolute brightness is the brightness that would be perceived if all stars were magically placed at the same standard distance. There can be a great difference between the total amount of radiation a star emits and the amount of radiation measured at the Earth's surface.

In astrophysics, we also use another scale of measurement where the apparent brightness is given by another magnitude of empirical origin: the apparent magnitude, which will be explained immediately below.

12.2.1.1.8 Apparent magnitude

Ptolemy in 9863 (holocence calendar) had defined a scale of six magnitudes to express the brightness (shining) of stars, the first for the brightest and the sixth for the stars just visible to the naked eye (6 magnitudes and therefore 5 gaps).

During the 119th century (holocene calendar), with the arrival of new photometric observations techniques (photographic and photoelectric), the scale of magnitude was replaced by that of "apparent magnitude" m that has been defined so that this new scale is close to the old one.

The definition is the following:

- The scale is logarithmic in base 10 (for convenience of the magnitude of manipulated quantities)
- There are 5 magnitude gaps corresponding to an apparent brightness ratio of 1 for 100 $(1:100)$
- The scale is inverse (high magnitude corresponds to a small apparent magnitude/ brightness).

Using these definitions, we can construct a way relating the shining (brilliance) of two stars to their apparent magnitude m.

For a star $S1$, one hundred times brighter than a star $S2$, the star $S1$ is 5 magnitude units above the star $S2$ (remember that the scale is reversed!). So a ratio of:

$$\frac{e_2}{e_1}=\frac{\dfrac{P_2}{d_2^2}}{\dfrac{P_1}{d_1^2}}=\frac{P_2}{P_1}\frac{d_1^2}{d_2^2}=100=10^2 \tag{12.2.97}$$

corresponds by definition to:

$$\Delta m=m_1-m_2=5 \tag{12.2.98}$$

We can then put the relations:

$$\log\left(\frac{e_2}{e_1}\right)\to 2 \quad \text{and} \quad m_1-m_2\to 5 \tag{12.2.99}$$

By applying the rule of three, we build:

$$\frac{\log\left(\dfrac{e_2}{e_1}\right)}{2}=\frac{m_1-m_2}{5} \tag{12.2.100}$$

By simplifying, we find the "Pogson's Formula" which expresses the relation between (visual) apparent magnitudes and brilliance (shining) of two stars:

$$\boxed{m=m_1-m_2=2.5\log\left(\frac{e_2}{e_1}\right)} \tag{12.2.101}$$

Then we are indeed compliant with the arbitrary rule summarized in the following figure:

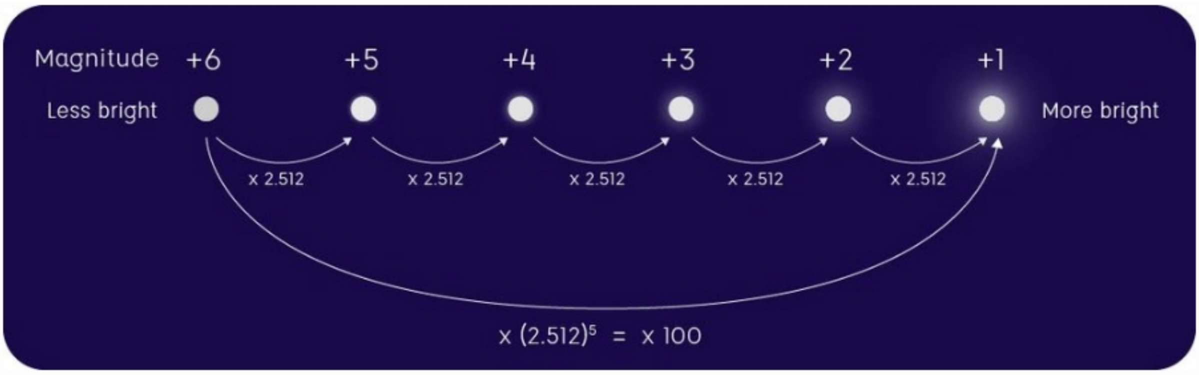

Figure 12.174: **Magnitude and brightness Ptolemy-Pogson relations**

A fourth magnitude star is 2.512 times as bright as a fifth magnitude star, and a second magnitude star is $(2.512)^4=39.82$ times brighter than a sixth magnitude star.

The following table shows how the difference in apparent magnitude between two stars (m_2-m_1) corresponds to the ratio of their apparent brightnesses (e_1/e_2):

Apparent magnitude difference $(m_2 - m_1)$	**Ratio of apparent brightness** (e_2/e_1)
1	2.512
2	$2.512^2 = 6.31$
3	$2.512^3 = 15.85$
4	$2.512^4 = 39.82$
5	$2.512^5 = 100$
10	$2.512^{10} = 10^4$
20	$2.512^{20} = 10^8$

Apart from small corrections, the brightness of Vega[27] (α Lyr) still serves as the definition of zero magnitude for visible and near infra-red wavelengths. The brightness of Vega is exceeded by four stars in the night sky at the 121st century (holocene calendar) at visible wavelengths (and more at infra-red wavelengths) as well as bright planets such as Venus, Mars, and Jupiter, and these must be described by negative magnitudes. For example, Sirius, the brightest star after the Sun (the latter having an apparent magntitude of 26.9) of the celestial sphere, has an apparent magnitude of -1.4.

To get an idea of the (visual) apparent magnitudes relatively to Vega here are some examples: Sun $m_\odot = -26.74$, full Moon $m = -15$, Venus maximum $m = -4.8$, Sirius $m = -1.4$ (spectral type A1 and distant of 8.6 light years), limit perceived with the naked eye 6, perception limit through an amateur telescope of 15 [cm] at this date (year 12003 according to holocene calendar) $m = 13$ limits of perception Hubble space telescope $m = 30$.

✍**Example:**

Now as we know that the apparent magnitude of the Sun (actually a G2V-type star, aka yellow dwarf) is -26.74 (brighter), and the mean apparent magnitude of the full Moon is -12.74 (dimmer) the difference in apparent magnitude is obviously that $\delta m = 14.00$

With this information reconsider that the Pogson formula also gives by construction the ratio of the luminosity. So relatively to our example we get:

$$-2.5\log\left(\frac{L}{L_\odot}\right) = 14 \qquad (12.2.102)$$

After rearranging we get therefore:

$$\frac{L}{L_\odot} = 10^{-14/2.5} \qquad (12.2.103)$$

Or better to have a nicer number:

$$\frac{L_\odot}{L} \cong 398,107 \qquad (12.2.104)$$

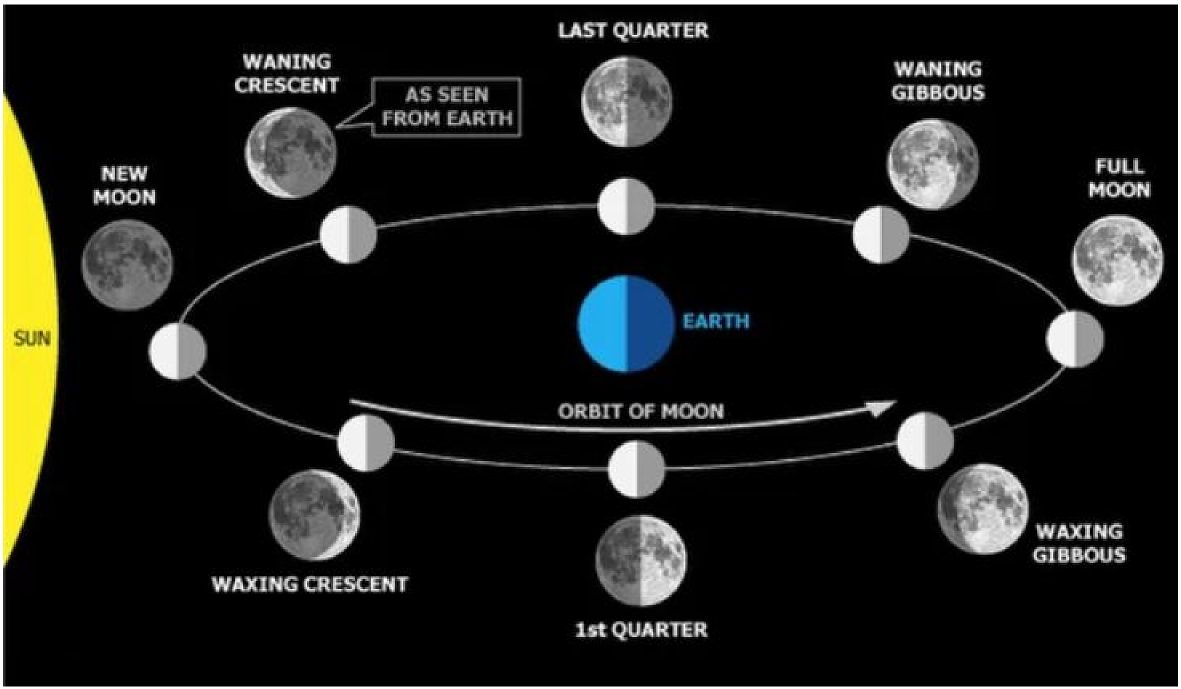
The Sun appears about $400,000$ times brighter than the full Moon.

---

[27] Brightest star in the constellation Lyra at this day (121st century according to holocene calendar). It is actually a relatively close star at only 25 light-years from Earth, and, together with Arcturus and Sirius, one of the most luminous stars in the Sun's neighbourhood

It should be noticed that the (visual) apparent magnitude does not exactly match the real apparent magnitude, because the eye is not equally sensitive to all wavelengths. The blue or red stars seem less bright to the eye than they actually are because some of the radiation is in the ultraviolet, respectively in the infra-red.

As one of my friend didn't know it (...) just a remark about the Moon... Many books and Internet websites show the classical following figure (where there is basically not too much to say about):



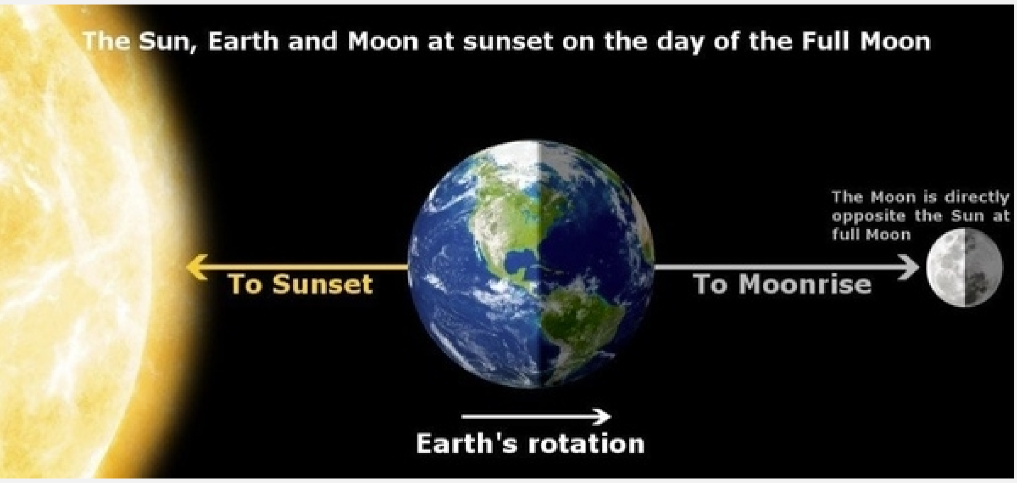
LAST QUARTER
WANING CRESCENT
AS SEEN FROM EARTH
WANING GIBBOUS
NEW MOON
FULL MOON
SUN
EARTH
ORBIT OF MOON
WAXING CRESCENT
WAXING GIBBOUS
1st QUARTER

Figure 12.175: Moon phases (source: ?)

Remark

Very rarely, if the conditions are just right, you may also be able to see an actual full Moon very close to the horizon and opposite to the Sun, during sunrise or sunset (a better denomination would be "at daybreak/nightfall"). In general, however, the Moon is always below the horizon while the Sun is up on the date of the full Moon.

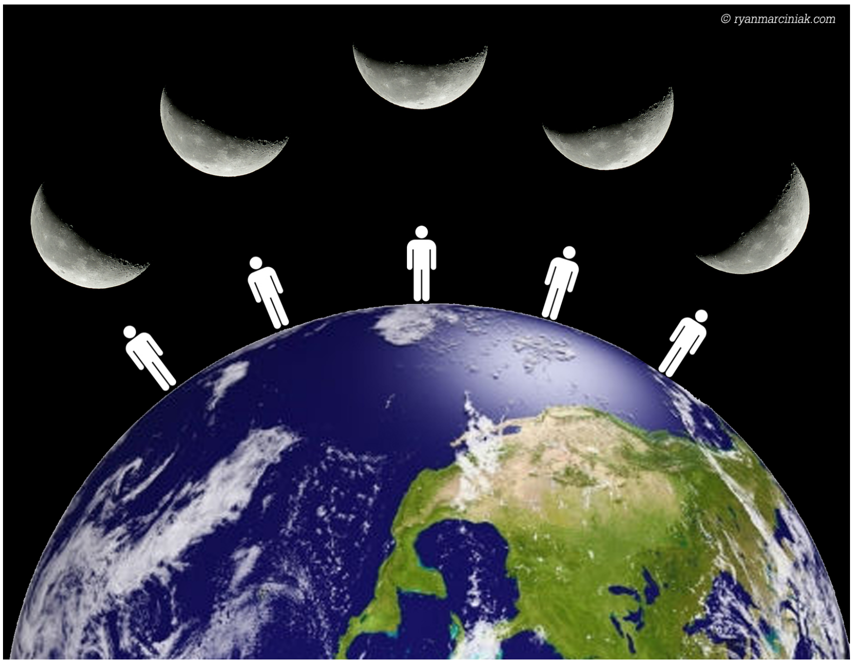
If you cannot understand how that works, it would appear you are maybe not trying hard enough or you are being stubbornly obtuse for your own reasons. Indeed, consider the situation below at full Moon:



The Sun, Earth and Moon at sunset on the day of the Full Moon
The Moon is directly opposite the Sun at full Moon
To Sunset
To Moonrise
Earth's rotation

Imagine now you are a human in Miami, Florida. You go outside and look to the West, and you see the Sun is setting, as the Earth is spinning from West to East (the terminator line that separates day from night moves to the west). Then you look to the East and see the full Moon that is rising in the east. It is facing the Sun just like the Earth off to your West is, and we are looking at its sunlit side, thus it is full. Occasionally, the Moon may actually be in the Earth's shadow, and it will turn dimly red for a few hours: a lunar eclipse.

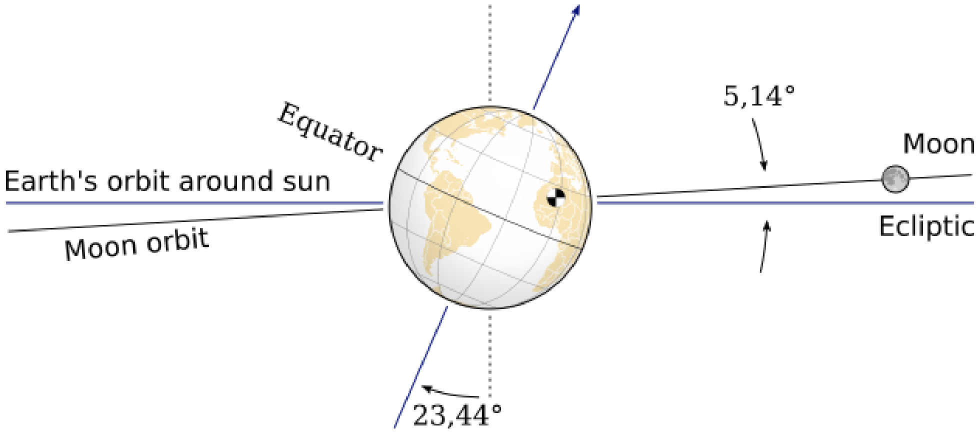
But this figure is omitting something important for earthlings (even if its implicit)... The Moon in the figure above is represented as seen from above the Solar System (perpendicular to the ecliptic plane) or as seen from a viewer at the North Pole. In-between the reality looks like this depending on your latitude:



© ryanmarciniak.com

It is therefore necessary to clarify whether it is a visual or bolometric apparent magnitude. In general, astrophysicists use bolometric magnitudes in their publications.

The reader must also keep in mind that the Moon isn't aligned on the ecliptic as illustrated below:



Equator
Earth's orbit around sun
Moon orbit
5,14°
Moon
Ecliptic
23,44°

Figure 12.176: **Moon and ecliptic angle**

But that using the average Moon-Earth distance and basic trigonometry we get that the Moon is:

$$\sin(5.14^\circ)\cdot 384,000 \cong 34,402 \tag{12.2.105}$$

kilometres above (and sometimes below) the ecliptic plane! Keeping in mind that Earth's radius is itself $6,371$ [km]! So the prior-previous figure like many similar figures in most textbooks and Internet websites is quite misleading!

This obliquity is the reason why we observe a Moon "libration", i.e. a cyclic variation in the apparent position of the Moon perceived by Earth-bound observers and caused by changes between the orbital and rotational planes of the moon. It causes an observer to see slightly different hemispheres of the surface at different times. That why over time, slightly more than half (about 59% in total) of the Moon's surface is seen from Earth due to libration and not only 50% as it would be the case without libration!

12.2.1.1.9 Absolute magnitude

The absolute magnitude M (not to be confused with the notation of emittance seen in the section of Geometrical Optics) of a star is also a logarithmic scale, expressing this time the bolometric luminosity L!!! It is the quantity presented in ordinate of the Hertzsprung-Russell diagram. The scale of this size is based however on the (visual) apparent magnitude.

The apparent magnitude and absolute magnitude are bound by the distance from the star. At constant intrinsic apparent brightness, the apparent brightness therefore decreases obviously with the square of the distance as we have already seen. In order to establish a relation, we had to choose a reference distance by a new definition.

Definition (#12.2.539): The "absolute magnitude" M of a star is equal to its apparent magnitude m if it is distant of 10 parsecs[28] (32.6 light years).

Therefore taking Pogon's formula that is for recall:

$$m_1 - m_2 = 2.5 \log\left(\frac{e_2}{e_1}\right) \tag{12.2.106}$$

---

[28] We take 10 parsecs to calculate absolute magnitude because it is a convenient distance that is large enough to minimize the effects of interstellar extinction (the dimming of light caused by dust and gas between the object and the observer), but small enough to be a reasonable distance to which to compare the brightness of stars and other celestial objects.

And changing the notations to make it corresponds to the previous definition:

$$m-M=2.5\log\left(\frac{e_2}{e_1}\right) \tag{12.2.107}$$

we get:

$$M=m-2.5\log\left(\frac{e_2}{e_1}\right) \tag{12.2.108}$$

And as:

$$\frac{e_2}{e_1}=\frac{\dfrac{P_2^2}{d_2^2}}{\dfrac{P_1^2}{d_1^2}} \tag{12.2.109}$$

But as it is the same star:

$$\frac{e_2}{e_1}=\frac{\dfrac{P_0^2}{d_2^2}}{\dfrac{P_0^2}{d_1^2}}=\frac{d_1^2}{d_2^2} \tag{12.2.110}$$

In our case this becomes:

$$\frac{e_2}{e_1}=\frac{d^2}{10^2} \tag{12.2.111}$$

Therefore:

$$M=m-2.5\log\left(\frac{e_2}{e_1}\right)=m-2.5\log\left(\frac{d^2}{10^2}\right)=m-2.5\left(2\log(d)-2\right) \tag{12.2.112}$$

So finally:

$$\boxed{M=m-5\left(\log(d)-1\right)} \tag{12.2.113}$$

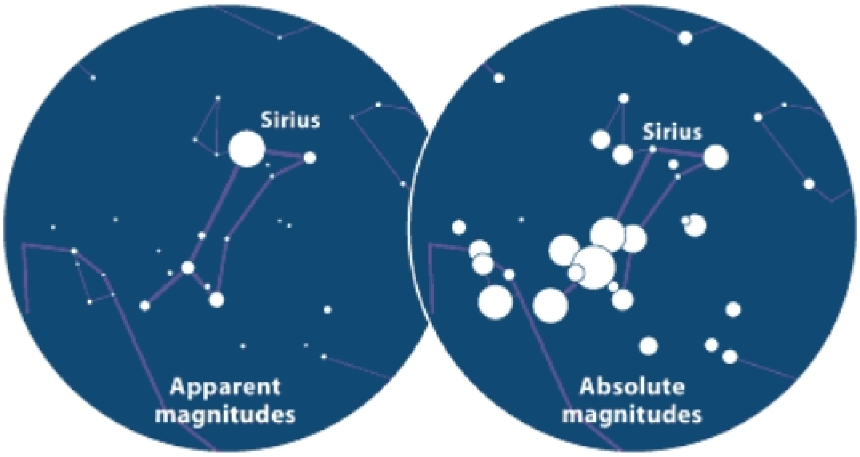

Figure 12.178: **Sirius apparent vs absolute magnitudes**

As the Sun-Earth distance in parsec is equal to $4.84814\cdot 10^{-6}$ we get:

$$m_{\odot}-M_{\odot}=5(\log(4.84814\cdot 10^{-6})-1)=-31.5721 \tag{12.2.114}$$

Therefore:

$$M_{\odot}=m_{\odot}+31.5721=-26.74+31.5721\cong 4.83 \tag{12.2.115}$$

Remark

For the absolute magnitude M to be accurate, we need stellar models, and know the temperature of the star as we will immediately see it. In practice, the only readily accessible quantity is obviously the observed magnitude, which is actually the combination of the apparent magnitude and the interstellar absorption.

The absolute magnitude can be obviously rewritten with respect to the absolute bolometric luminosity of the Sun (actually a G2V-type star, aka yellow dwarf):

$$M=m_{\text{bol},\odot}-2.5\log\left(\frac{L_{\text{bol}}}{L_{\text{bol},\odot}}\right) \tag{12.2.116}$$

We put for the Sun that $L_{\text{bol},\odot}=1$. Therefore it remains:

$$\boxed{M=m_{\text{bol},\odot}-2.5\log(L_{\text{bol}})} \tag{12.2.117}$$

This latter relation of comparison of the absolute magnitude with the apparent magnitude (which is the actually magnitude observed on Earth) allows estimation d of the distance of the object in astrophysics.

Using the expression of the bolometric luminosity proved earlier above:

$$L_{\text{bol}}=\left(\frac{T}{T_{\odot}}\right)^4\left(\frac{r}{r_{\odot}}\right)^2 \tag{12.2.118}$$

the absolute magnitude of star being a direct function of its temperature and radius we can then write:

$$M=m_{\text{bol},\odot}-2.5\log\left(\left(\frac{T}{T_{\odot}}\right)^4\left(\frac{r}{r_{\odot}}\right)^2\right)=m_{\text{bol},\odot}-10\log\left(\frac{T}{T_{\odot}}\right)-5\log\left(\frac{r}{r_{\odot}}\right) \tag{12.2.119}$$

This is the result we wanted to prove from the beginning: the absolute bolometric magnitude is directly related to the bolometric luminosity of the star, which is why it is one that most interests astrophysicists.

Remark

The distance to nearby stars could be determined by the satellite Hipparcos. By measuring the parallax (measurements of the star position at six-month intervals and applying basic trigonometric rules as seen in the section Astronomy). But beyond a few tens of parsecs, measuring the distance of stars by parallax becomes very imprecise. By studying the spectrum of the star, we can determine its spectral class, its surface temperature and place in the Hertzsprung-Russell diagram. It is therefore possible to estimate its absolute magnitude and roughly calculate its distance.

This measurement trick is fundamental to cosmology. It is the way we determines the distance to nearby galaxies by measuring the period of some variable stars (we will focus a little bit on that further below).

The distance of distant galaxies is calculated by measuring the apparent magnitude of supernovae that occur in it. Indeed, the absolute magnitudes of Type Ia supernovae (we recognize them by the lack of hydrogen spectrum lines, and by the decrease in brightness) are well calibrated because the energy released by these stellar explosions is relatively constant.

The stars of the main sequence of the Hertzsprung-Russell diagram are very stable objects. The gravitational force, which tends to contract the star, is exactly compensated by the internal pressure forces, which tend to dilate it. It's when the star becomes a red giant that sometimes the balance is upset. Thus began a phase of instability which results in significant variations in the brightness of the star.

The breaking of balance is caused by a complex phenomenon that involves variations of transparency of helium layers near the surface of the star. From there, the star begins to experience a series of expansions and contractions controlled by the forces that were formerly balance. When the pressure force prevails, the volume of the star increases. But the gravity slows the movement and eventually cause contraction. The volume of the star will pass below its average value, until the internal pressure opposes the contraction and managed to cause further expansion.

It is not the size changes that cause the variations in brightness, but those of the temperature. Indeed, as we have prove it earlier above, the brightness of a star varies with the fourth power of the temperature, while it varies with the square of the radius following for recall:

$$L_{\text{bol}}=\left(\frac{T}{T_{\odot}}\right)^4\left(\frac{r}{r_{\odot}}\right)^2 \tag{12.2.120}$$

When the volume of the star, however, is lower than average, the temperature is slightly higher and the brightness maximum. At the opposite, the temperature is slightly lower than average and the brightness minimum. The brightness of the star thus changes periodically, hence the name of "variable star" or "pulsative variable star".

It exists in the Hertzsprung-Russell diagram of a band of instability that crosses this diagram almost vertically just to produce the thermal phenomena in question.

The two main types of pulsating variables are the Cepheids and RR Lyrae stars. These bodies play a central role in astrophysics. Cepheids are stars of a few solar masses. They are in the helium burning phase after reaching the red giant stage. The stars of solar mass arrived at this point become RR-Lyrae stars. Their brightness varies with a period of between one day and several weeks. The remarkable property of Cepheids is the existence of a relation between the average brightness and the period of their oscillations. For example, the average brightness is $1,000$ times that of the Sun for a period of days and $10,000$ times that amount for a period of several weeks. It is this relation that makes Cepheids one of the basic tools of astrophysics.

Ok now that we know a few main concepts, it is time to introduce the following interesting data table about a few stars:

Star Name	**Latin Name**	m	**Distance [LY]**	**Spectral Type**	L **[L$_\odot$]**	T **[K]**	M **[M$_\odot$]**	R **[R$_\odot$]**
Sun	Sol	-26.9	0.000016	G2 V	1	$5,800$	1	1
Sirius	α Canis Majoris	-1.46	8.6	A1 V	25.4	$10,000$	2.5	2.2

Table 12.18: **Some stars data table**

It seems that a significant percentage of practitioners (and students!) agree that all these different concepts related to a light source are quickly a mess! We have tried below to summarize all the concepts introduced earlier above (sadly we never saw such a table in other textbooks):

Name(s)	**Definition**	**Formulation**	**Units** (SI)
Brightness (intrinsic bolometric brightness)	Total power radiated in the entire electromagnetic spectrum in the direction of the observer expressed relatively to the total power radiated by the Sun	$L_{\text{bo}}=\dfrac{P_{\text{star}}}{P_\odot}$	None
Illuminance (semi-bolometric illuminance)	Measure of how much the incident light illuminates the surface, wavelength-weighted by the luminosity function to correlate with human brightness perception	$E_\nu=K_m\int\limits_{380}^{780}M(\lambda,T)V(\lambda)\mathrm{d}\lambda$	$[\mathrm{J}\cdot\mathrm{s}^{-1}]$
Shining (apparent brightness) (flux) (brilliance)	Total power radiated in the direction of the observer divided by the sphere surface with the radius equal to the distance which separates the observer from the source	$b=\dfrac{P_{\text{star}}}{S_{\text{obs.}}}$	$[\mathrm{W}\cdot\mathrm{m}^{-2}]$
Emittance (luminous emittance) (irradiance) (emissive power) (radiant emittance)	Radiant flux emitted by a surface by unit of its area	$M_e=\dfrac{\Phi}{S}=\varepsilon\sigma T^4$	$[\mathrm{W}\cdot\mathrm{m}^{-2}]$
Relative Emittance (thermal emittance) (emmisivity)	Ratio of the total emissive power of a body to the total emissive power of a perfectly black body at that temperature	$\varepsilon=\dfrac{M_e}{M_e^\circ}=\dfrac{\varepsilon\sigma T^4}{\sigma T^4}$	None
Spectral Emittance (spectral exitance)	Radiant flux emitted by a surface by unit area per unit frequency (or per unit wavelenght)	$M_\nu=\dfrac{\partial M}{\partial\nu}$	$[\mathrm{W}\cdot\mathrm{m}^{-2}\cdot\mathrm{s}]$
Luminosity	Luminosity is the total amount of electromagnetic energy emitted per unit of time by an object.	L	[W]
Apparent magnitude	Empirical scale to compare the brilliance of an object relatively to another one (commonly Vega α Lyr is taken as zero reference)	$m=2.5\log_{10}\left(\dfrac{L}{L_{\text{ref}}}\right)$	None
Absolute magnitude	The absolute magnitude M_a of a star is the magnitude m the star would have if it was placed at a distance of 10 parsecs from Earth.	$M_a=m-5\left(\log_{10}(d)-1\right)$	None

Table 12.19: **Summary of most common visibility criteria in astrophysics with their traditional notation and units according to international system (SI)**

12.2.1.1.9.1 Why are stars not visible on most space photos and videos

In this early 121st century (holocene calendar), the intrinsic luminosity of Sirius is 25.4 times greater than that of the Sun (actually a G2V-type star, aka yellow dwarf). However, Sirius is about 8.6 light-years away from Earth (or $d = 8.13 \cdot 10^{16}$ meters), while our Sun is just 8 light-minutes. Now, since the apparent brightness is affected by geometric dilution (it falls off as the inverse-square of the distance as we know), Sirius appears to us much fainter than the Sun! As the luminosity of the Sun is $3.828 \cdot 10^{26}$ [W], we then have for Sirius:

$$b_{\text{Sirius}} = \frac{L_{\text{Sirius}}}{4\pi d^2} = \frac{25.4 \cdot 3.828 \cdot 10^{26}}{4\pi \left(8.13 \cdot 10^{16}\right)^2} = 1.35 \cdot 10^{-7}\ [\mathrm{W} \cdot \mathrm{m}^{-2}] \qquad (12.2.121)$$

If we consider the distance Moon-Earth as negligible in comparison of Sirius-Earth distance we can consider that the same flux reaches the Moon in first approximation!

If the reader wants to redo the calculations with other stars here is a small list:

Name of star	Distance/light-years	Luminosity
Sun	$1.58 \cdot 10^{-5}$	1.0
Sirius	8.6	25
Cancpus	310	1100
Alpha Centauri	4.4	1.5
Arcturus	37	170
Vega	25	40

Table 12.20: **Some stars, distances and luminosities**

The astronomer Robert Trumpler showed in 11930 (holocene calendar) that interstellar gas and dust absorbs light at a typical rate of 2 magnitudes (one magnitude being for reminder a factor of 2.512) per kiloparsec ($3,262$ light-years). Sirius being at only 8.6 light years we then have:

$$b_{\text{Sirius}} = 1.35 \cdot 10^{-7} \left(1 - \frac{8.6}{3,262} \cdot 2.512\right) = 1.34 \cdot 10^{-7}\ [\mathrm{W} \cdot \mathrm{m}^{-2}] \qquad (12.2.122)$$

We can consider Sirius as a black body at $25,200$ [K] according to the latest available measurement, therefore using Planck's distribution function (see section Thermodynamics page 3724), the visible light corresponds to:

$$\text{Prc. visible} = \frac{M_{\text{tot.}}(T)}{M_{\text{vis.}}(T)} = \frac{2\pi \frac{h}{c^2} \int\limits_{400\cdot 10^{12}}^{700\cdot 10^{12}} \frac{\nu^3}{e^{\frac{h\nu}{kT}} - 1} \mathrm{d}\nu}{2\pi \frac{h}{c^2} \int\limits_{0}^{+\infty} \frac{\nu^3}{e^{\frac{h\nu}{kT}} - 1} \mathrm{d}\nu} = \frac{\int\limits_{400\cdot 10^{12}}^{700\cdot 10^{12}} \frac{\nu^3}{e^{\frac{h\nu}{kT}} - 1} \mathrm{d}\nu}{\int\limits_{0}^{+\infty} \frac{\nu^3}{e^{\frac{h\nu}{kT}} - 1} \mathrm{d}\nu} \cong 5.45\% \qquad (12.2.123)$$

Then:

$$b_{\text{Sirius,vis.}} \cong 5.45\% \cdot 1.34 \cdot 10^{-7} = 7.31 \cdot 10^{-9}\ [\mathrm{W} \cdot \mathrm{m}^{-2}] \qquad (12.2.124)$$

Assuming the average photon energy in visible light, i.e. $3.61 \cdot 10^{-19}$ [J], we get therefore:

$$N = \frac{7.31 \cdot 10^{-9}}{3.61 \cdot 10^{-19}} \cong 2.02 \cdot 10^{10}\ [\text{photons} \cdot \mathrm{s}^{-1} \cdot \mathrm{m}^{-2}] \qquad (12.2.125)$$

visible photons received by Sirius on Moon by square meter and per second.

If we consider a camera like the one taken by Apollo mission on the Moon in 11969 (according to holocence calendar), i.e. Hasselblad 500EL Data with 80mm Zeiss lens (lens having a global transmissivity of 98%) f/11 with a Kodak Panatomic-X 70mm ISO 160 stereo film with shutter speed of $1/250$ [s], then the number of visible photons received from Sirius on such an apparatus during a photo capture is approximately of[29]:

$$n_{\text{Hasselbad}}=\frac{2.02\cdot 10^{10}}{250}\pi\left(\frac{0.08}{2\cdot 11}\right)^2\cdot 98\%\cong 3,300\;[\text{photons}] \tag{12.2.126}$$

So that's kinda the number of photons received for each square millimetre of the Kodak film during a shoot.

Remark

For a modern CCD camera of the early 121st century (holocene calendar) recording a 4K movie at a frame rate (fps) of 24 per seconds with the same aperture and focal and transmissivity, we get:

$$n_{\text{CC}}=\frac{2.02\cdot 10^{10}}{24}\pi\left(\frac{0.08}{2\cdot 11}\right)^2\cdot 98\%\cong 34,375\;[\text{photons}]$$

As far as we know Kodak films were made of a cellulose acetate film base (kind of gelatine containing dispersed silver halide (AgX[30] crystals but in practice it's mostly AgBr) that is strongly reactive to light) and according to some sources, the number of photons necessary to activate silver halide back to it's metallic state is between 7 and 30 photons[31] (we will take 18 as an average). Furthermore, the minimum number of silver halide it takes inside a cluster to form a latent image (usable for photo development and visible at human eye) in a grain is between[32] 5 and 50 (we will take 27 as an average)! However the scattering of the electrons of silver halide (or whatever) by the incoming light isn't 100%. We then speak of "quantum efficiency" η_q (i.e. the ratio of the number of incoming photons over the number of electrons which they produce)! Sadly we cannot found the quantum efficiency of the exact Kodak film used by the Apollo camera. We were just able to find an upper bound for Kodak Royal-X films in 430 [nm] wavelength of $\eta_q=0.073\%$ and in 607 [nm] of $\eta_q=0.59\%$ from a paper of 11958 according to holocene calendar (see [176]). Another paper of 12001 according to holocene calendar (see [373]) claim that in practice, the quantum efficiency of photographic systems is often only about $\eta_q=20\%$. An internal paper at NASA of 11964 according to holocene calendar (see [248]) claim the quantum efficiency of the best photographic emulsions is of $\eta_q=0.1\%$. Finally and electric engineer claim on an Internet forum in 12018 according to holocene calendar that the quantum efficiency is of $\eta_q=5\%$... So let us take the average of these number. That leads us to the following number of efficient photons:

$$n_{\text{Hasselbad,eff.}}=3,300\cdot\bar{\eta}_q=3,300\cdot 5.15\%\cong 170\;[\text{photons}] \tag{12.2.127}$$

---

[29] The Apollo crew had different model of cameras with different lenses and different stereo films! Not just one!

[30] There are about $100,000$ silver halide crystals per square millimetre photographic image, each crystal is often 0.03 to 20 microns in size depending on the ISO of the film!

[31] For more information see *Silver Halides in Photography* from Yen. T. Tan

[32] This depends on the makeup of the emulsion, hence different film sensitivities!

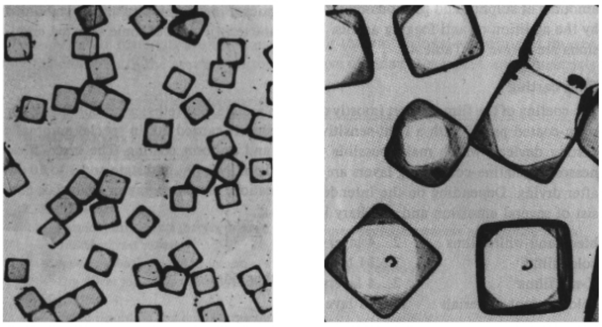
Remark

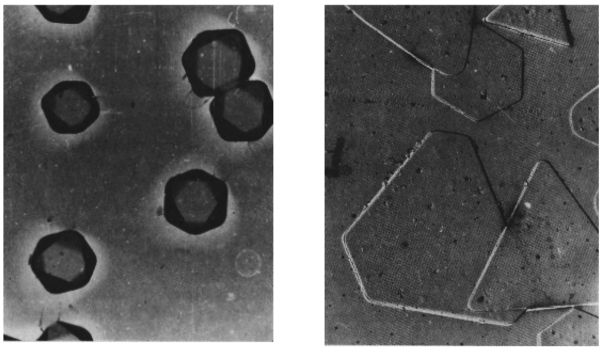
For a modern CCD camera of the early 121st century (holocene calendar) we have on average on the global visible spectrum

$$n_{\text{CCD,eff.}} = 34,375 \cdot \bar{\eta}_q = 34,375 \cdot 70\% \cong 24,000\,[\text{photons}]$$

The size of AgX grains (for information, the higher a film stock's ISO is, the bigger the silver crystals are, the ISO 100 series are around 6 microns) determines the chemical amplification factor during the image development (the gain is about 10^8). The larger the grains the larger the amplification factor and the more sensitive the photographic film. Large grains, however, obviously decrease the spatial resolution of the picture and imply an increased thickness of the photographic emulsion.



AgBr cubes tetrahedrons



octahedrons tabular grains

Figure 12.181: **Various** AgX **grain morphology (i.e. "film grain")**

Therefore we have:

$$n_{\text{Kodak,halide}} = \frac{170}{18 \cdot 27} \cong 0.35\,[\text{grains}] \tag{12.2.128}$$

So the number of photons and the quantum efficiency is not even enough to activate on silver halide!

Remark

For a modern CCD camera of the early 121st century (holocene calendar) the number of photons necessary to activate one pixel is of the order of 10^5 (see page [400]). Hence:

$$n_{\text{CCD,pixel}} = \frac{24,000}{10^5} \cong 0.24\,[\text{pixel}]$$

So not even enough to activate one pixel! So the conclusion doesn't change for modern CCD cameras recording 4K movies in space with the same kind of settings!

Furthermore... (!!!) ... once we have the reaction of silver halide molecule the reader has to know that the latter are not completely stable. The new reaction can disintegrate after a few minutes from interactions with chemicals from the emulsion dyes, oxygen and water molecules (for more see [122] and [49]). After a few minutes you start to loose reactive silver halide. If we have tenth of thousands of them then we can afford to loose a few. If we have only a few of them (here in our calculations we have even less than one...) then the odds of them surviving the film development is low!

So now we know why we can see some stars or not at all the photos of the Apollo mission but the crew was able to see the stars as the human eye needs only between 7 and 30 photons to send a signal to the brain.

Remark

The reader must keep in mind that the pictures are taken in lunar daytime - the sky is black due to absence of air, not because it is night. Our brains want to see stars in a black sky. The astronauts could see the stars, but the star's light output could not compete with the Sun-blasted lunar surface in a camera exposure. You could try shooting the ground and sky at a lit sport field at night, the same thing would happen!

Here below we can see that the contrast makes that the stars in the background are not visible:

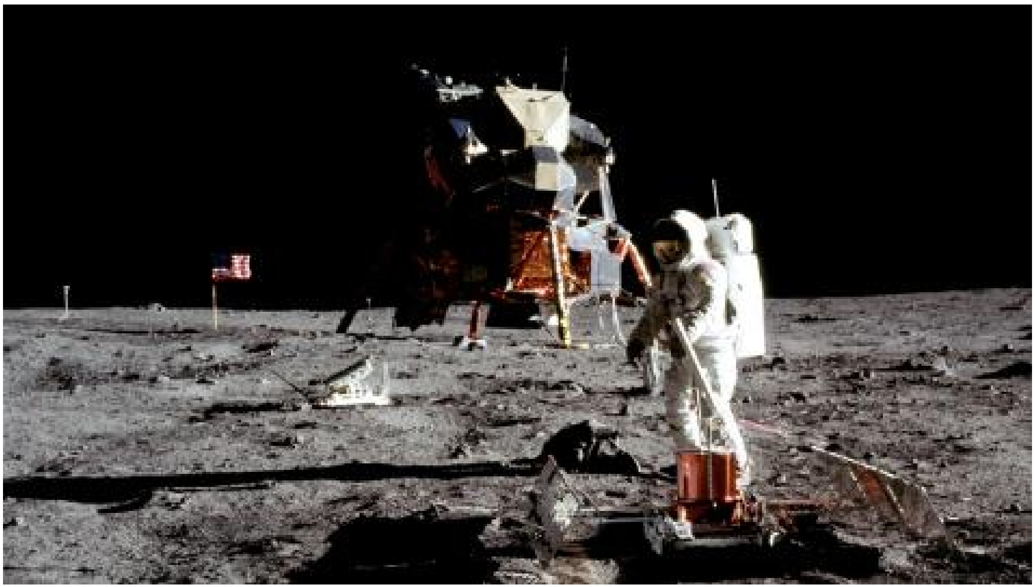


Figure 12.182: **21 July 11969 Appolo 11 mission photo of Buzz Aldrin taken by Neil Armstrong (credit: NASA)**

But here in the same mission (stage separation) the contrast and shutter speed is no too high so we can see some stars in the background:

Or in this quite relatively high contrast photo still from the same mission we can see some stars in the background as the shutter speed wasn't very likely to $1/250$ [s]:

For the human eye, having an average exposure time of $1/15$th of a second and the cornea a radius of 7.4 millimetre with a f/2 at rest, we get in vacuum (i.e. still on the Moon):

$$n_{\text{Hum. eye}} \cong \frac{1.87\cdot 10^{10}}{15}\pi\left(\frac{0.0074}{2}\right)^2 \cong 53,000\,[\text{photons}]$$

Even on Earth where 43% on visible light is in average absorbed by the atmosphere, we till get:

$$n_{\text{Hum. eye,Earth}} \cong 43\%\cdot 53,000 \cong 22,790\,[\text{photons}]$$

Knowing that the eye needs between 7 to 30 photons to consider an object as visible we understand why it's not a problem to see Sirius in the night sky with naked eyes. Obviously you can't see Sirius in the day sky as the background luminosity (blue of the atmosphere) is much brighter than the brightness of Sirius itself. This is related to the concept of "Signal to Noise ratio"!

12.2.1.1.10 Eddington limit

Radiation exerts a pressure. This implies that in luminous systems there is an outwards force by the outgoing luminosity, in addition to the gravitational force pulling[33] the gas inwards. In the Sun, this radiative force is more than 10,000 times smaller than the gravitational pull, but in more massive stars, this outward radiative force can approach the force of gravity.

---

[33] Keep in mind that's in the framework of the Newtonian model of gravity as we that in General Relativity there are no "pull".

Under the classical picture, one cannot surpass the Eddington limit while keeping the system in steady state, because nothing could balance the net force outwards, and gas will necessarily be accelerated outwards, thereby "evaporating" the system. In a supernova explosion, for example, the large fluxes accelerate gas outwards and the systems are quite far from a steady state, so the limit does not apply. But in systems which remain intact for durations much longer than their dynamical time scale, the limit should be relevant, at least according to the classical picture.

Therefore the "Eddington luminosity", also referred to as the "Eddington limit", is the maximum luminosity a body (such as a star) can achieve when there is balance between the force of radiation acting outward and the gravitational force acting inward. The state of balance is named "hydrostatic equilibrium". When a star exceeds the Eddington luminosity, it will initiate a very intense radiation-driven stellar wind from its outer layers. The Eddington limit is invoked to explain the observed luminosity of accrediting Black Holes such as quasars. This relates to the fact that in the 120th century (holocene calendar) gravity was considered inadequate to explain the Sun (actually a G2V-type star, aka yellow dwarf) power, so physicists moved to the nuclear reactions explanations. However nuclear reaction were inadequate to explain powerful objects in the Universe like quasars. So the accretion onto compact objects is a powerful mechanism for producing high energy radiation.

Originally, Arthur Eddington took only the electron scattering into account when calculating this limit, something that now is named the "classical Eddington limit". Nowadays, the "modified Eddington limit" also counts on other radiation processes such as bound-free and free-free radiation interactions.

The limit is obtained by setting the outward radiation pressure equal to the inward gravitational force. Both forces decrease by inverse square laws as we will prove it, so once equality is reached, the hydrodynamic flow is the same throughout the star.

The radiation force equals the rate at which the electron absorbs the photons momentum:

$$F_{\text{rad}}=\frac{\Delta p}{\Delta t}=\frac{\Delta N_\gamma}{\Delta t}p_\gamma \tag{12.2.129}$$

We know that we have for a single photon momentum:

$$p_\gamma=\frac{h\nu}{c} \tag{12.2.130}$$

Therefore:

$$F_{\text{rad}}=\frac{\Delta N_\gamma}{\Delta t}p_\gamma=\frac{\Delta N_\gamma}{\Delta t}\frac{h\nu}{c} \tag{12.2.131}$$

But we can use the bolometric intrinsic luminosity (see section Astronomy page 5336), and under the assumptions of Thomson scattering the fraction of photons scattered at distance r given by (see section Atomistic page 5100):

$$f_T=\frac{\sigma_T}{4\pi r^2} \tag{12.2.132}$$

(do not confuse the notation with that of frequency...!) such that:

$$\frac{\Delta N_\gamma}{\Delta t}=\frac{L}{h\nu}f_T=\frac{L}{hv}\frac{\sigma_T}{4\pi r^2} \tag{12.2.133}$$

Therefore:

$$F_{\text{rad}}=\frac{\Delta N_\gamma}{\Delta t}\frac{h\nu}{c}=\frac{L}{hv}\frac{\sigma_T}{4\pi r^2}f_T\frac{h\nu}{c}=\frac{L\sigma_T}{4\pi cr^2} \qquad (12.2.134)$$

In the limit case when the gravitational force is balanced by the radiation pressure force:

$$F_{\text{grav}}=F_{\text{rad}} \qquad (12.2.135)$$

Accreting material being mainly fully ionised hydrogen we have:

$$F_{\text{grav}}=\frac{GM}{r^2}(m_p+m_e)\cong\frac{GM}{r^2}m_p \qquad (12.2.136)$$

Therefore:

$$F_{\text{grav}}=F_{\text{rad}}\rightarrow\frac{GM}{r^2}m_p\cong\frac{L\sigma_T}{4\pi cr^2} \qquad (12.2.137)$$

Therefore for pure ionized hydrogen under the assumption of Thomson scattering and in hydrostatic spherical equilibrium we get the maximum luminosity due to accretion:

$$\boxed{L_{\text{Edd}}\cong\frac{4\pi GMm_pc}{\sigma_T}} \qquad (12.2.138)$$

Notice that the only parameter in this formula is the mass of the star. All other numbers are constants of nature! That latter is sometimes denoted:

$$L_{\text{Edd}}\cong\frac{4\pi GMm_pc}{\sigma_{\text{T}}}\cong 1.26\cdot 10^{31}\left(\frac{M}{M_\odot}\right)\;[\text{W}] \qquad (12.2.139)$$

where $M_\odot$ is the mass of the Sun and $L_\odot$ is the luminosity of the Sun (actually a G2V-type star, aka yellow dwarf). Then it is immediate that for the special case of the Sun, we get immediately:

$$L_{\text{Edd}}\cong 1.26\cdot 10^{31}\;[\text{W}] \qquad (12.2.140)$$

The reader must really keep in mind that the Eddington limit is not a strict limit on the luminosity of a stellar object! The limit does not consider several potentially important factors, and super-Eddington objects have been observed!

Now we set the gravitational energy of an accreted proton-electron pair to be equal to the total thermal energy of the two particles:

$$\frac{GM}{R}(m_p+m_e)\cong\frac{GM}{R}m_p=2\cdot\frac{3}{2}kT \qquad (12.2.141)$$

Therefore the temperature that the accreted material would reach if the gravitational energy is turned entirely in thermal energy is given by:

$$T_{\text{acc}}\cong\frac{GMm_p}{3kR} \qquad (12.2.142)$$

An application for a White Dwarf of radius $R=10,000$ [km] and $M=1M_\odot$ gives approximately $T_{\text{acc}}\cong 5\cdot 10^5$ [K]. An application for a Neutron star of radius $R=10$ [km] and $M=1.4M_\odot$ gives approximately $T_{\text{acc}}\cong 8\cdot 10^{11}$ [K].

For Black Holes we have something interesting... We have proved at page 5849 that the innermost stable circular orbit (ISCO) for a non-rotating Black Hole was:

$$r_{\text{ISCO}} = \frac{6GM}{c^2} \tag{12.2.143}$$

Therefore:

$$T_{\text{acc}} \cong \frac{GMm_p}{3kR} = \frac{GMm_p}{3kr_{\text{ISCO}}} = \frac{c^2 m_p}{18k} \cong 6 \cdot 10^{11}\,[\text{K}] \tag{12.2.144}$$

So that the Eddington temperature is in first approximation independent of the non-rotating Black Hole mass itself! A kind of Universal constant...

The implications of Eddington limit are multiple in Astrophysics. It is useful to mention only some of them:

- If it is possible to measure (or derive) the Eddington luminosity of a star, it is possible to determine its mass.
- It can fix an upper limit also on the temperature of a star and of the accretion matter.

Remark

It is interesting to compare:

$$L_{\text{Edd}} \cong \frac{4\pi GMm_p c}{\sigma_T} \cong 1.26 \cdot 10^{31} \left(\frac{M}{M_\odot}\right)$$

with the intrinsic bolometric luminosity:

$$L_{\text{star}} = 4\pi R_{\text{star}}^2 \sigma T_{\text{star}}^4 \cong 7.13 \cdot 10^{-7} R_{\text{star}}^2 T_{\text{star}}^4$$

In the huge majority of cases (if we plug in the two relations above the star having the biggest radius, the biggest mass and the hottest temperature):

$$L_{\text{star}} < L_{\text{Edd}}$$

In fact, this is only a rough estimate. It assumes that the accreting material is ionized hydrogen (a good assumption) and that the celestial object (star or Black Hole) is accreting uniformly from all directions (which is not a good assumption). The Eddington luminosity may be exceeded, for example, if accretion occurs primarily from one direction and the resulting radiation emerges in a different direction. Nonetheless, it is a useful approximation that we will use again during our study of Black Holes later (see page 5835).

12.2.1.2 Pulsative Variable Stars

The stars of the main sequence of the Hertzsprung-Russell diagram are very stable objects. The gravitational force, which tends to contract the star, is exactly compensated by the internal pressure forces, which tend to dilate it. It's when the star becomes a red giant that sometimes the balance is upset. Thus began a phase of instability which results in significant variations in the brightness of the star.

The breaking of balance is caused by a complex phenomenon that involves variations of transparency of helium layers near the surface of the star. From there, the star begins to experience a series of expansions and contractions controlled by the forces that were formerly balance. When the pressure force prevails, the volume of the star increases. But the gravity slows the movement and eventually cause contraction. The volume of the star will pass below its average value, until the internal pressure opposes the contraction and managed to cause further expansion.

Remark

The pulsating variable star that is the prototype for one of the most influential classes of variable stars in astronomy was discovered in 11784 (holocene calendar) by John Goodricke. He was the first to observe the periodic and asymmetric light variation of δ Cephei2 in the same year as he discovered the eclipsing binary star β Lyrae. The first known variable star was identified in 11638 (holocene calendar) when Johannes Holwarda noticed that Omicron Ceti (later named Mira) pulsated in a cycle taking 11 months. Interestingly, this star had previously been described as a nova by David Fabricius in 11596 (holocene calendar). The discovery of variable stars, along with observations of supernovae in 11572 and 11604 (holocene calendar), challenged the ancient belief that the starry sky was eternally unchanging.

It is not the size changes that cause the variations in brightness, but those of the temperature. Indeed, as we have prove it earlier above, the brightness of a star varies with the fourth power of the temperature, while it varies with the square of the radius following for recall:

$$L_{\text{bol}}=\left(\frac{T}{T_{\odot}}\right)^4\left(\frac{r}{r_{\odot}}\right)^2 \tag{12.2.145}$$

When the volume of the star, however, is lower than average, the temperature is slightly higher and the brightness maximum. At the opposite, the temperature is slightly lower than average and the brightness minimum. The brightness of the star thus changes periodically, hence the name of "variable star" or "pulsative variable star".

It exists in the Hertzsprung-Russell diagram of a band of instability that crosses this diagram almost vertically just to produce the thermal phenomena in question.

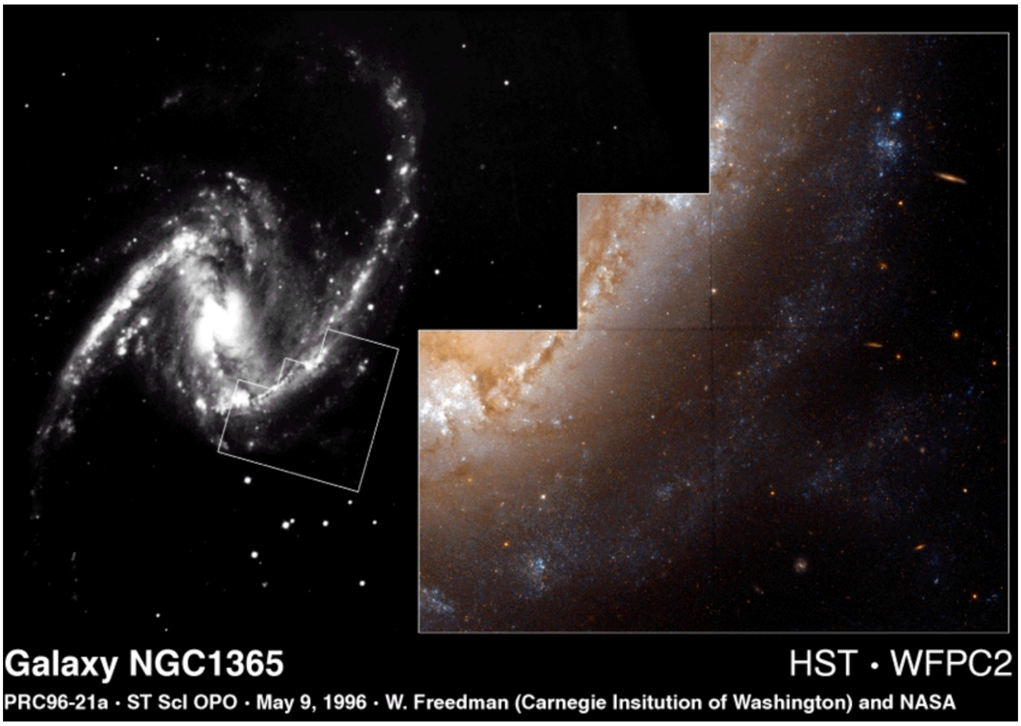
The two main types of pulsating variables are the Cepheids and RR Lyrae stars. These bodies play a central role in astrophysics. Cepheids are stars of a few solar masses. They are in the helium burning phase after reaching the red giant stage. The stars of solar mass arrived at this point become RR-Lyrae stars. Their brightness varies with a period of between one day and several weeks. The remarkable property of Cepheids is the existence of a relation between the average brightness and the period of their oscillations. For example, the average brightness is $1,000$ times that of the Sun for a period of days and $10,000$ times that amount for a period of several weeks. It is this relation that makes Cepheids one of the basic tools of astrophysics.

If we know this relationship for a variable star, it is relatively easy, by the determination its period to derive its absolute magnitude M. By then measuring its apparent magnitude m we can then calculate the distance in parsec with of the relation proved earlier above:

$$M = m - 5(\log(d) - 1) \tag{12.2.146}$$

One of the main reasons for constructing the Hubble Space Telescope (HST) was to measure light curves of Cepheid variables in other galaxies. It is especially important to use Cepheids to measure distances to the galaxies in two nearby clusters: the Virgo Cluster (the nearest rich cluster), and the Fornax Cluster (a somewhat sparser collection of galaxies).

HST can zoom in on a small portion of a galaxy to find and measure Cepheids:



Galaxy NGC1365
HST • WFPC2
PRC96-21a • ST ScI OPO • May 9, 1996 • W. Freedman (Carnegie Insitution of Washington) and NASA

and the zoom inside the area of interest:

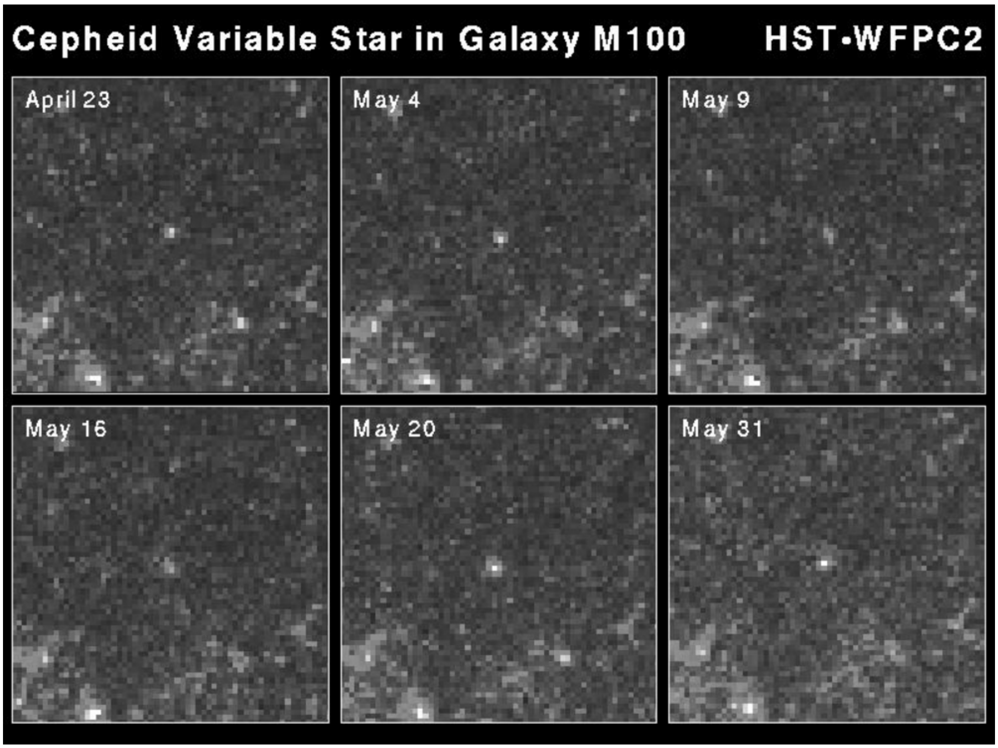


Figure 12.183: **Hubble Space Telescope Cepheid measurement**

The empirical period-luminosity relation for classical Cepheids was discovered in 11908 (holocene calendar) by Henrietta Swan Leavitt in an investigation of thousands of variable stars in the Magellanic Clouds. She published it in 11912 (holocene calendar) with further evidence. Once the period-luminosity relationship is calibrated, the luminosity of a given Cepheid whose period is known can be established. Their distance is then found from their apparent brightness. The period-luminosity relationship has been calibrated by many astronomers throughout the 120th century (holocene calendar), beginning with Hertzsprung. Calibrating the period-luminosity relation has been problematic; however, a firm Galactic calibration was established by Benedict et al. 12007 (holocene calendar) using precise HST parallaxes for 10 nearby classical Cepheids. Also, in 12008 (holocene calendar), ESO astronomers estimated with a precision within 1% the distance to the Cepheid RS Puppis, using light echos from a nebula in which it is embedded. However, that latter finding has been actively debated in the literature.

The following relationship between a Population I Cepheid's period P_T (in days) and its mean absolute magnitude $\bar{M}$ was established from Hubble Space Telescope trigonometric parallaxes for 10 nearby Cepheids:

$$\bar{M} = (-2.43 \pm 0.12)(\log(P_T) - 1) - (4.05 \pm 0.02) \tag{12.2.147}$$

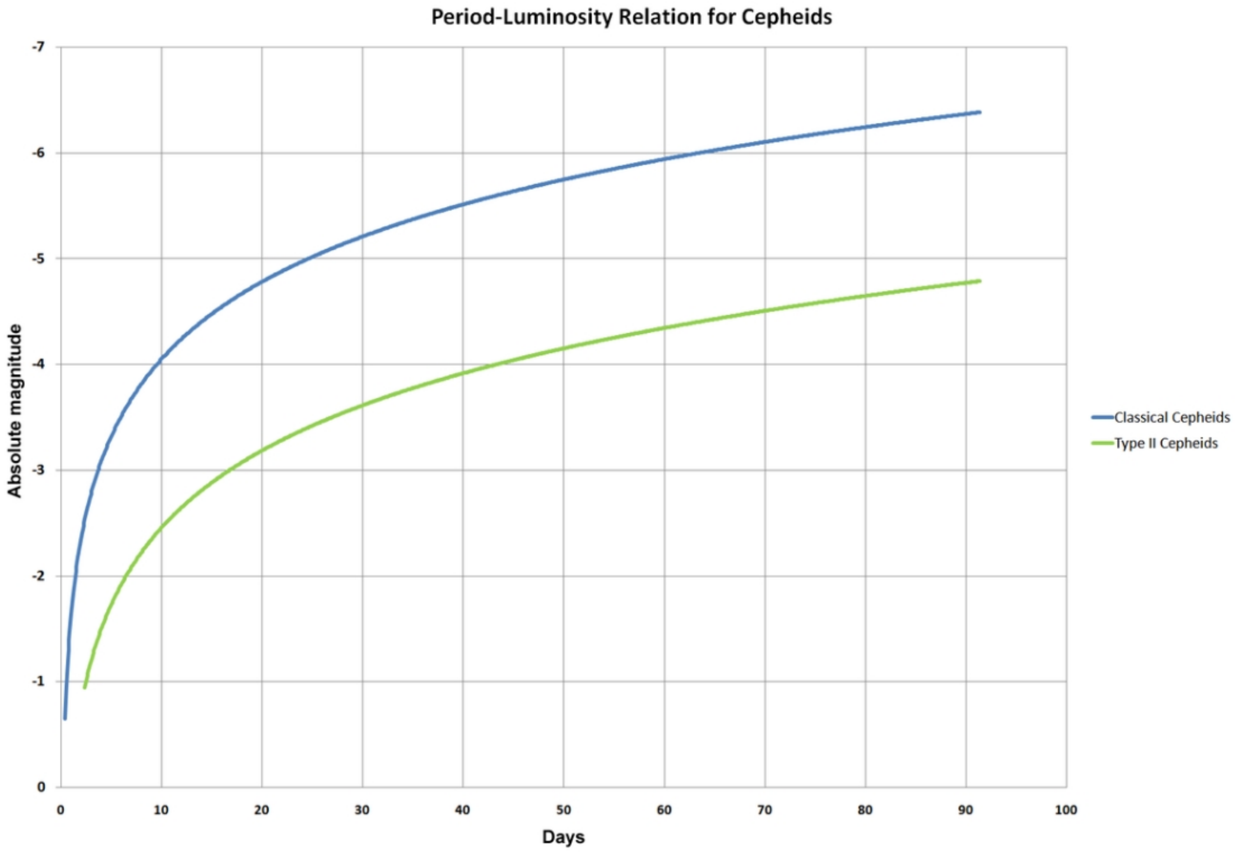

Figure 12.184: **Cepheid absolute magnitude-period plot (source: Wikipedia)**

Let us now try to derive theoretically such a period-luminosity relation! For this, we assume that fluid object (including a star) of radius R has a fundamental pulsation period:

$$P_T \cong \frac{2R}{v_s} \tag{12.2.148}$$

where v_s is the sound speed. This is simply the time it takes a sound (or pressure) wave to cross the stellar diameter! But we have proved in the section of Music Mathematics (see page 8202) that in the case of longitudinal sound waves in an isothermal gas we had the Newton-Laplace speed of sound relation:

$$v_s = \sqrt{\frac{\gamma P}{\rho_0}} \tag{12.2.149}$$

But we know from virial theorem (see section Continuum Mechanics page 3897)

$$U = 2T \tag{12.2.150}$$

Or written according to Astrophysics notation:

$$E_p = 2E_c \tag{12.2.151}$$

Replacing E_p by the potential gravific energy and E_c by the kinetic of a particle in a gas, we get (we have already seen that also during our study of viriel theorem):

$$\frac{GM^2}{R} = \cancel{2}\left(\frac{3}{\cancel{2}}kNT\right) \tag{12.2.152}$$

Using the relation (also proved during our study of the Newton-Laplace speed of sound relation):

$$v_s=\sqrt{\frac{\gamma NkT}{M}} \tag{12.2.153}$$

we get:

$$\frac{GM^2}{R}=3kN\left(\frac{v_s^2M}{\gamma Nk}\right)=\frac{3v_s^2M}{\gamma} \tag{12.2.154}$$

where we take for the Poisson constant $\gamma=5/3$ as proved in the section of Thermodynamics (see page 3647) for an ideal mono-atomic gas.

The pulsation period is then:

$$P_T\cong\frac{2R}{v_s}\cong\frac{2R}{\sqrt{\dfrac{GM^2\gamma}{3RM}}}\cong\frac{2R}{\sqrt{\dfrac{GM5}{9R}}}=\sqrt{\frac{4R^2}{\dfrac{5GM}{9R}})}=\sqrt{\frac{36R^3}{5GM}} \tag{12.2.155}$$

Plugging in numbers and normalizing with Solar mass and radius, we get:

$$P_T\cong 4271.773\left(\frac{R}{R_{\odot}}\right)^{3/2}\left(\frac{M_{\odot}}{M}\right)^{1/2} \tag{12.2.156}$$

One can derive the period-luminosity law as follows: Assume a sample of stars of the same mass (classical Cepheids have masses of $5-10$ solar masses), and the same temperature (the instability strip is approximately vertical in the H-R diagram). The bolometric luminosity then scales as R^2 as we have proved earlier above:

$$L_{\text{bol}}=\left(\frac{T}{T_{\odot}}\right)\left(\frac{R}{R_{\odot}}\right)^2 \tag{12.2.157}$$

The pulse period scales as $R^{3/2}$ (see above!). Then it follows immediately that:

$$P_T\propto L_{\text{bol}}^{3/4} \tag{12.2.158}$$

As we know we have also:

$$M\propto -2.5\log(L_{\text{bol}}) \tag{12.2.159}$$

Therefore:

$$L_{\text{bol}}\propto 10^{-M/2.5} \tag{12.2.160}$$

Hence:

$$P_T\propto L_{\text{bol}}^{3/4}\propto\left(10^{-M/2.5}\right)^{3/4} \tag{12.2.161}$$

If we take the logarithm (it is more common in the field of Astrophysics...), we then get the "cepheid period-luminosity relation" (even if it should be named... "cepheid period-absolute magnitude relation" instead):

$$\boxed{\log(P_T)\propto\frac{3}{4}\cdot\left(-\frac{1}{2.5}\right)M=-0.3M} \tag{12.2.162}$$

As we can see we are not too far from the experimental relation obtained thanks to Hubble observations given above (where we had $\log(P_T)\propto -0.4\bar{M}$).

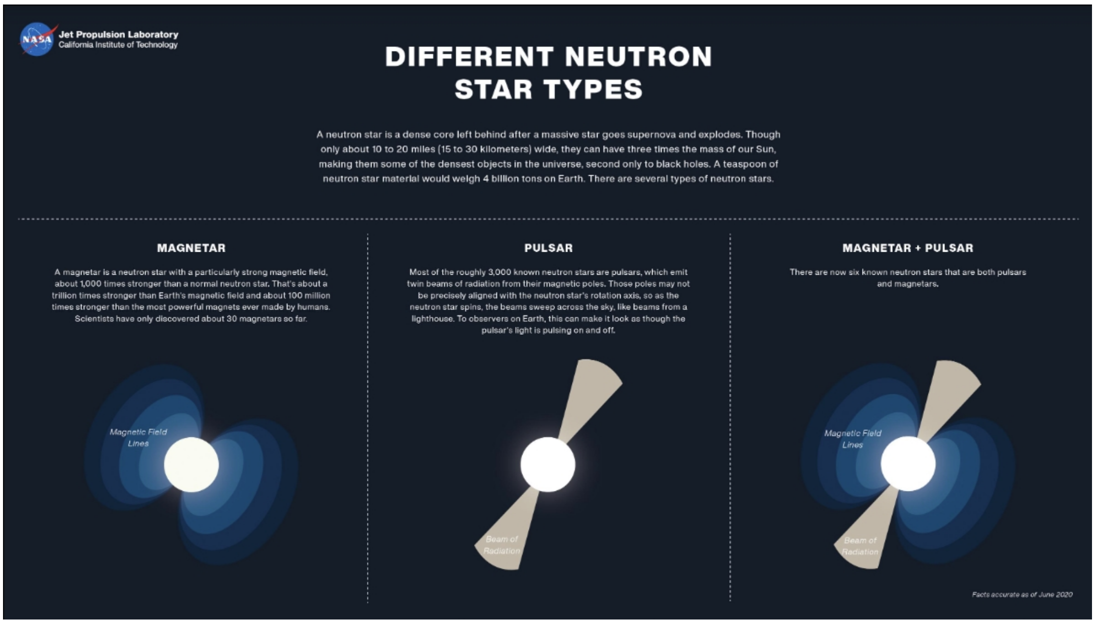
Remark

If any reader knows a more robust derivation and result and is in possessions of the detailed developments, don't hesitate to share the corresponding LaTeX text with us.

Cepheids aren't perfect distance indicators. For one thing, their brightness and periods of pulsation can vary with their chemical composition. There's also the problem of crowding and confusion: what if our view of a distant galaxy appears to show a single, varying Cepheid star... but is really a combination of light from the Cepheid and several nearby stars, all mixed together?

12.2.1.3 Neutron Stars (magnetars/pulsars)

A "neutron star" is the collapsed core of a large star (10 to 29 solar masses). Neutron stars are the smallest and densest stars known to exist. With a radius on the order of 10 [km], they can, however, have a mass of about twice that of the Sun (actually a G2V-type star, aka yellow dwarf). They result from the supernova explosion of a massive star, combined with gravitational collapse, that compresses the core past the White Dwarf star density to that of atomic nuclei (by the process of electron capture see in the section of Nuclear Physics at page 5088). Most of the basic models for these objects imply that neutron stars are composed almost entirely of neutrons, which are subatomic particles with no net electrical charge and with slightly larger mass than protons. They are supported against further collapse by neutron degeneracy pressure, a phenomenon described by the Pauli exclusion principle (see further below). If the remnant has too great a density, something which occurs in excess of an upper limit of the size of neutron stars at 2-3 solar masses, it will continue collapsing to form a Black Hole (see proof further below).



DIFFERENT NEUTRON STAR TYPES

A neutron star is a dense core left behind after a massive star goes supernova and explodes. Though only about 10 to 20 miles (15 to 30 kilometers) wide, they can have three times the mass of our Sun, making them some of the densest objects in the universe, second only to black holes. A teaspoon of neutron star material would weigh 4 billion tons on Earth. There are several types of neutron stars.

MAGNETAR

A magnetar is a neutron star with a particularly strong magnetic field, about 1,000 times stronger than a normal neutron star. That's about a trillion times stronger than Earth's magnetic field and about 100 million times stronger than the most powerful magnets ever made by humans. Scientists have only discovered about 30 magnetars so far.

PULSAR

Most of the roughly 3,000 known neutron stars are pulsars, which emit twin beams of radiation from their magnetic poles. Those poles may not be precisely aligned with the neutron star's rotation axis, so as the neutron star spins, the beams sweep across the sky, like beams from a lighthouse. To observers on Earth, this can make it look as though the pulsar's light is pulsing on and off.

MAGNETAR + PULSAR

There are now six known neutron stars that are both pulsars and magnetars.

Figure 12.185: **Infography of different types of Neutron Stars (source: Jet Propulsion Laboratory/NASA)**

Most neutron stars know so far are pulsars. However when a neutron star spin slow down enough, it no longer radiate very much energy, and so it is no longer considered a pulsar. This usually happens within a few million years. Magnetars are differentiated from other neutron stars by having even stronger magnetic fields, and by rotating more slowly in comparison. Most magnetars know so far rotate once every two to ten seconds, whereas typical neutron stars, observed as radio pulsars, rotate one to ten times per second.

12.2.1.3.1 Chandrasekhar limit

We have already determined in the section of Classical Mechanics (see page 3234) the Schwarzschild radius (in its classical form) that expresses the critical radius of a body for the release speed to it surface to be equal to that of speed of light. We obtained the following relation which typically expressed the radius that have a given celestial object to have a release speed equal to that of light:

$$R=\frac{2GM}{c^2} \tag{12.2.163}$$

In this particular case the star is what we named a "Black Hole". However, before the Black Hole, a star passes as we have spoken, by several intermediate steps by which it can also stabilize. Thus, you have often had to read in the literature that for a White Dwarf to collapse into a neutron star, its mass must be greater than 1.4 solar masses but without mathematical proof. Well, that's what we're going to demonstrate now!

We will introduce the subject by studying the influence of the uncertainty principle on the size of an atomic system (it limits the minimum dimension). This example is very powerful because it shows that the uncertainty principle not only governs the process of measurement but also the overall behaviour of quantum systems.

The first example that we can give is that of the hydrogen atom, not that we are expecting a new result from this method of analysis, but rather because we can expose the use of the principle of uncertainty and insist on its meaning.

We admit that the proton, whose mass far exceeds that of the electron, can be considered fixed. The energy of the electron is written:

$$E_{\text{tot}}=\frac{1}{2}m_e v^2-\frac{q_e^2}{4\pi\varepsilon_0 r}=\frac{p^2}{2m_e}-\frac{q_e^2}{4\pi\varepsilon_0 r} \tag{12.2.164}$$

In classical physics, a system whose energy is given by the previous relation does not have a minimum: if we tend r toward zero by keeping the circular shape of the orbit, it is easy to see E_{tot} tends to $-\infty$. On the other hand, in quantum physics, this limit has no meaning: the principle of uncertainty opposes to it.

In this case, the search for the minimum E_1 of E_{tot} takes a meaning, since a constraint appears which maintains this minimum at a finite value. It is determined in quantum physics (see the Bohr model of the atom in the section of Quantum Corpuscular Physics page 4626) and requires:

$$p\cdot r=n\cdot\hbar=\hbar \tag{12.2.165}$$

where $n\in\mathbb{N}$. However, this relation aside, if the radius r of the atom becomes too small under external constraints (be careful, we get rid of the quantized orbits of the Bohr model of the atom which imposes a constraint on p) the linear momentum p of the electron can not be less than the uncertainty Δp imposed by the uncertainty principle of Heisenberg (see section Quantum Wave Mechanics page 4704), since Δx is of the order of the radius r of the atom. The shape itself of the preceding relation limits the scope of the method: we cannot expect to determine better than an order of magnitude of the minimum of E_{tot}.

In order to evaluate the minimum E_1 of total energy, which we interpret as the ground state of the hydrogen atom, we calculate the minimum of E_{tot} by eliminating p from the expression:

$$E_{\text{tot}}=\frac{p^2}{2m_e}-\frac{q_e^2}{4\pi\varepsilon_0 r} \qquad (12.2.166)$$

by:

$$p\cdot r=n\cdot\hbar=\hbar \qquad (12.2.167)$$

We get:

$$E_{\text{tot}}:=E(r)=\frac{\hbar^2}{2m_e r^2}-\frac{q_e^2}{4\pi\varepsilon_e r} \qquad (12.2.168)$$

The radius r_1 of the atom in the ground state is the value of r that gives $E(r)$ its minimum value:

$$\left.\frac{\mathrm{d}E(r)}{\mathrm{d}r}\right|_{r=r_1}=-\frac{\hbar^2}{m_e r_1^3}+\frac{q_e^2}{4\pi\varepsilon_0 r_1^2}=0 \qquad (12.2.169)$$

which is the well-known expression of the Bohr radius seen in the section of Corpuscular Quantum Physics during our study of the Bohr model of the atom. The energy E_1 of the ground state is now easily calculable.

The purpose of this example is to show that with Heisenberg's uncertainty principle we can by very simple reasoning find the fundamental state of a system. This is exactly how we will proceed to determine the conditions that cause a star to return to its ground state.

Let us attack now the study of a star. Schematically it consists of a mixture of two gases: one that is formed of nuclei on the one hand, and the electronic gas on the other.

During the life of the star, many fusion processes took place. They each increased the size and mass of the nuclei. The iron (Fe), which is abundant at the end of a star's life, contains an average of 56 nucleons (see section Nuclear Physics page 5019).

These nuclei are of a chemical or isotopic variety. As they are few in comparison with electrons, their pressure is that of a charged conventional gas, neutralized by the presence of electrons: it can be ignored, especially since the temperature is zero.

The electronic charge alone would not allow the electrons to resist the collapse of a star since the stellar matter is neutral. At very low temperatures, when the fuel is exhausted, the only pressure that the electronic gas can oppose to the hydrostatic pressure due to gravity is of quantum origin.

As a first approximation, the electrons thus exert on each other an apparent repulsion which is not of Coulomb origin (Pauli exclusion principle). As a first approximation, they obey a relation analogous to that of the atomic electron and which is written in the minimal case (or maximum of pressure):

$$p \cdot d \cong \hbar \tag{12.2.170}$$

where d is the average distance between two neighbouring electrons.

At the temperature $T = 0$ [K] equilibrium is reached when the total energy (the matter of the star) of the system is minimal.

What happens if we try to evaluate the variation of the radius r_{WD} of the White Dwarf as a function of its mass m_{WD}?

The gravitational potential energy of a star is given in good approximation by (see section Classical Mechanics page 3351):

$$E_p \cong -G\frac{m_{\text{WD}}^2}{r_{\text{WD}}} \tag{12.2.171}$$

The mass m_{WD} is approximately given by:

$$m_{\text{WD}} = m_p N \tag{12.2.172}$$

where m_p is the mass of the proton and N the number of nucleons contained in the star: the contribution of the electrons to the mass of the star is negligible and there is no need to distinguish between the mass of the neutron and that of the proton, almost identical.

The second contribution to energy is essentially that of the degenerate electronic gas (degeneration corresponds for recall to the existence of several states having the same energy), of kinetic origin. We could be tempted to write simply (assuming that the number of electrons is equal to the number of nucleons since we are for recall in the simplified hypothesis of a hydrogen gas):

$$E_c = N\frac{1}{2}m_e v^2 = \frac{Np^2}{2m_e} \tag{12.2.173}$$

This way of doing things leads to a dead end. If we request that the sum $E_p + E_c$ reaches a minimum value, we arrive at a value of the radius of the star so small that, by application of the relation:

$$p \cdot d \cong \hbar \tag{12.2.174}$$

the average velocity of the electrons v would exceed that of the light!

To avoid this contradiction, we have to use relativistic mechanics that showed us that, in this case (see section Special Relativity page 5627), we can express the total energy as:

$$E_{\text{tot}} = c\sqrt{m_{0e}^2 c^2 + p^2} \tag{12.2.175}$$

if the numerical value of the kinetic energy significantly outweighs that of the energy at rest, then we have:

$$E_{\text{tot}} = Nc\sqrt{m_{0e}^2 c^2 + p^2} = N(E_c + m_{0e}c^2) \tag{12.2.176}$$

and therefore:

$$E_{\text{tot}} \cong E_c = N m_{0e} c^2 = Npc \tag{12.2.177}$$

The average distance d between electrons is evaluated by assuming that the star is homogeneous, a sufficient approximation when we are looking for the order of magnitude of an average. We further simplify the geometry by admitting that each electron is surrounded by a spherical domain of radius d in which there is no other electron of the same spin and where we can count only one electron of opposite spin. Since then:

$$d^3 \cong \frac{r_{\text{WD}}^3}{N} \tag{12.2.178}$$

It remains to evaluate the minimum of the sum:

$$E_{\text{tot}} = E_p + E_c \cong -G\frac{m_p^2 N^2}{r_{\text{WD}}} + Npc \tag{12.2.179}$$

given the condition:

$$m_{\text{WD}} = m_p N \tag{12.2.180}$$

Then it comes:

$$p \cong \frac{\hbar}{d} \cong \frac{\hbar N^{1/3}}{r_{\text{WD}}} \tag{12.2.181}$$

and then:

$$E_{\text{tot}} = E_{\text{WD}}(r_{\text{WD}}) \cong -G\frac{m_p^2 N^2}{r_{\text{WD}}} + Nc\frac{\hbar}{r_{\text{WD}}}N^{1/3} = \frac{N^{1/3}}{r_{\text{WD}}}(c\hbar + G m_p^2 N^{2/3}) \tag{12.2.182}$$

that we write finally:

$$E_{\text{tot}} = E_{\text{WD}}(r_{\text{WD}}) \cong \frac{N^{1/3}}{r_{\text{WD}}}(c\hbar - G m_p^{4/3} m_{\text{WD}}^{2/3}) \tag{12.2.183}$$

Faced with this result, we are confronted with an unexpected situation. Indeed, if the factor:

$$K = c\hbar - G m_p^{4/3} m_{\text{WD}}^{2/3} \tag{12.2.184}$$

is positive, then the total energy of the White Dwarf is also positive, which means that the system is unbounded: the star is totally unstable (it has not reached its minimum energy threshold). It can only reduce its energy by increasing its radius without limits.

We see that the K factor is negative if:

$$m_{\text{WD}} > \left(\frac{c\hbar}{G}\right)^{3/2} \frac{1}{m_p^2} \tag{12.2.185}$$

If the White Dwarf exceeds this mass then we can no longer deal with the problem with the previous equations. It then satisfies the equations governing a star composed only of neutrons (neutron star) and this is then another problem that we will not tackle here for now.

The (approximate) mass of the famous "Chandrasekhar limit" is thus given by:

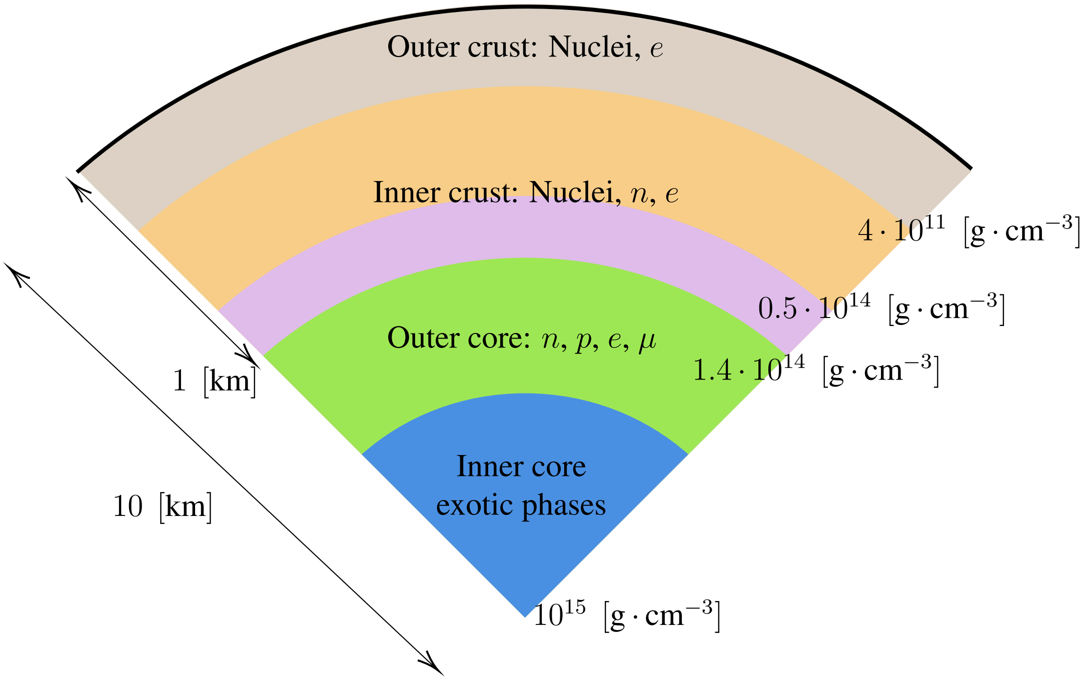
$$m_{\text{WD}} = m_C = \left(\frac{c\hbar}{G}\right)^{3/2} \frac{1}{m_p^2} \tag{12.2.186}$$

It constitutes the mass beyond which a White Dwarf collapses into a Neutron star.

Conventionally, astrophysicists associate this limit value with a multiplying factor of the mass of the Sun $M_\odot$. We actually (numerically):

$$\boxed{m_{\text{WD}} = m_C = \left(\frac{c\hbar}{G}\right)^{3/2} \frac{1}{m_p^2} = 1.4 M_\odot} \tag{12.2.187}$$

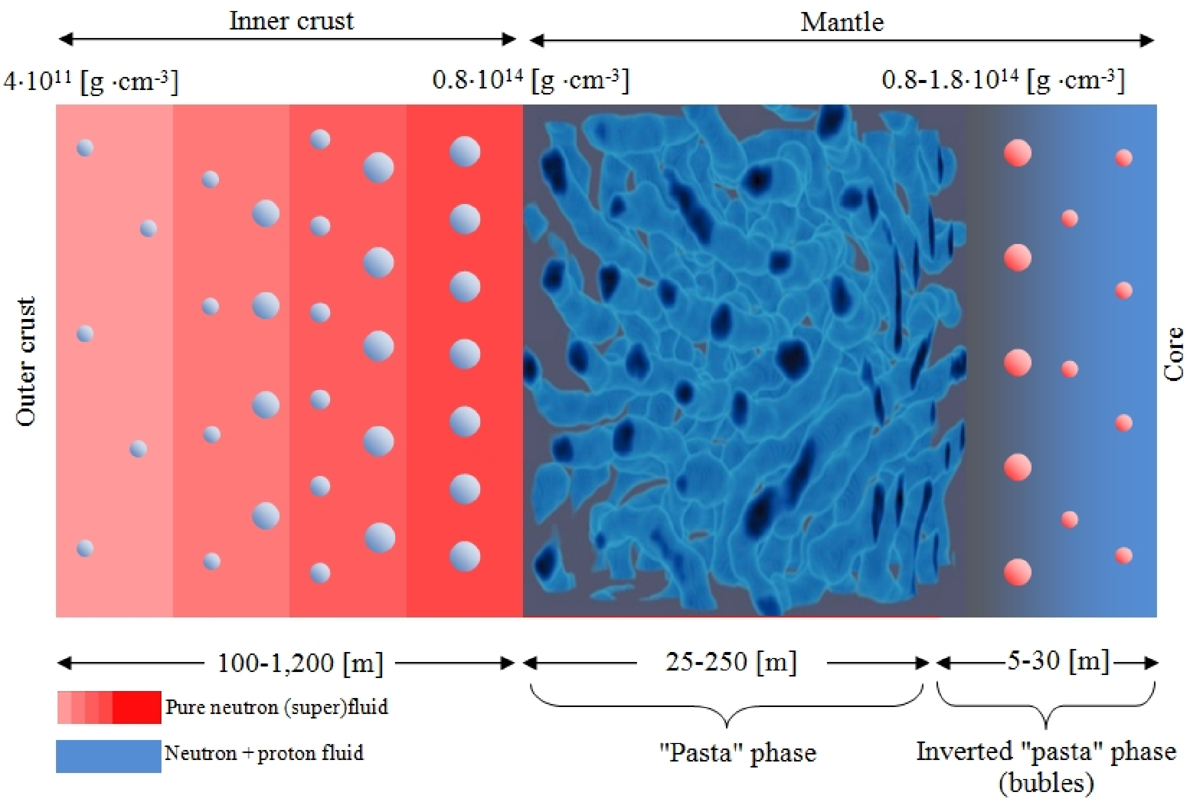
In the figure below on the left we have schematic slice through a neutron star. Letters N, n, p, e, μ refer to the presence of nuclei, fluid neutrons and protons, electrons and muons, respectively. The inner core composition is still uncertain and various exotic possibilities exist, including hyperons and deconfined quark matter.



Outer crust: Nuclei, e
Inner crust: Nuclei, n, e
Outer core: n, p, e, μ
Inner core
exotic phases
$4 \cdot 10^{11}$ [g · cm^{-3}]
$0.5 \cdot 10^{14}$ [g · cm^{-3}]
$1.4 \cdot 10^{14}$ [g · cm^{-3}]
10^{15} [g · cm^{-3}]
1 [km]
10 [km]

Figure 12.186: **Neutron star slice**

On the figure below we have an overview of what we expect to be the composition of the inner crust in a neutron star:



Inner crust
Mantle
4·10¹¹ [g ·cm⁻³]
0.8·10¹⁴ [g ·cm⁻³]
0.8-1.8·10¹⁴ [g ·cm⁻³]
Outer crust
Core
100-1,200 [m]
25-250 [m]
5-30 [m]
Pure neutron (super)fluid
Neutron + proton fluid
"Pasta" phase
Inverted "pasta" phase
(bubles)

Figure 12.187: Neutron star inner crust

At lower densities, a lattice of super-heavy, neutron-rich nuclei is immersed in a fluid of neutrons (which are likely to be superfluid) and a relativistic electron gas. At high enough densities the nuclei might deform and connect along certain directions to form extended tubes, sheets and bubbles of nuclear matter. These nuclear pasta phases might form a layer at the base of the neutron star crust, sometimes referred to as the mantle. Ranges of density and thickness given for each layer represent current uncertainties in the physics of neutron star crusts.

12.2.1.3.2 Rotation break limit

Let us make the simplifying assumption that the limit speed of rotation of a star (planet or star) is that which balances the centrifugal (fictional) force and gravitational force on the surface of the star such that we are led to write (see section Classical Mechanics page 3248):

$$m\frac{v^2}{R}=\frac{GMm}{R^2} \tag{12.2.188}$$

Write this relation supposes obviously that there is no connection other than the gravity which intervenes in the internal cohesion of the star. So the rotational time values we are going to get represent an upper bound (in the sense that the actual value is probably smaller).

It then comes from the previous relation:

$$v=\sqrt{\frac{GM}{R}} \tag{12.2.189}$$

To get the rotation time to which it corresponds, it suffices to divide the perimeter at the equator by its speed:

$$\boxed{t_r=\frac{2\pi R}{v}=\frac{2\pi R}{\sqrt{\dfrac{GM}{R}}}=\frac{2\pi R}{\sqrt{\dfrac{6.674\cdot 10^{-11}M}{R}}}}\tag{12.2.190}$$

So, for the Earth, we have as limit period of rotation before rupture:

$$t_{r,\text{Earth}}=\frac{2\pi\cdot 6,378,137}{\sqrt{\dfrac{6.674\cdot 10^{-11}\cdot 5.9736\cdot 10^{24}}{6,378,137}}}\cong 84\,[\text{min}]\tag{12.2.191}$$

For the Sun:

$$t_{r,\text{Sun}}=\frac{2\pi\cdot 1,392,000,000}{\sqrt{\dfrac{6.674\cdot 10^{-11}\cdot 1.9891\cdot 10^{30}}{1,392,000,000}}}\cong 7.8\,[\text{h}]\tag{12.2.192}$$

Let us now consider the case of the pulsar NP0532 which has a rotation of 33 milliseconds[34]. We would like to determine its radius. We then have using the previous relations:

$$R=\left(\frac{t_r\sqrt{GM}}{2\pi}\right)^{2/3}\tag{12.2.193}$$

Using the theoretical relation of the Chandrasekhar mass limit (since a pulsar is a Neutron star rotating rapidly on itself):

$$m_{\text{WD}}=m_C=\left(\frac{c\hbar}{G}\right)^{3/2}\frac{1}{m_p^2}=1.4M_{\odot}\tag{12.2.194}$$

We then have for the radius of the smallest possible pulsar according to these hypotheses (and approximations...):

$$\boxed{R_{\text{min}}=\left(\frac{t_r\sqrt{G\cdot 1.4M_{\odot}}}{2\pi}\right)^{2/3}}\tag{12.2.195}$$

With the following numerical application (using data from the Crab pulsar):

$$R=\left(\frac{t_r\sqrt{G\cdot 1.4M_{\odot}}}{2\pi}\right)^{2/3}=\left(\frac{33\cdot 10^{-3}\sqrt{6.674\cdot 10^{-11}\cdot 1.4\cdot 1.9891\cdot 10^{30}}}{2\pi}\right)^{2/3}\cong 172\,[\text{km}]\tag{12.2.196}$$

With the pulsar millisecond PSR J1748-2446ad having a period of 1.39 milliseconds we then fall on[35]:

$$R=\left(\frac{t_r\sqrt{G\cdot 1.4M_{\odot}}}{2\pi}\right)^{2/3}\cong 21\,[\text{km}]\tag{12.2.197}$$

---

[34] In the beginning of the 121st century (holocene calendar) there is a project of NASA of using pulsars as interplanetary GPS.

[35] The slowest know pulsar known at the day we write these lines is PSR J0250+5854 with a rotation period of 23.5 [s]. The faster pulsar is PSR J1748-2446ad with a rotation period of 0.00139 [s]

what is remarkable (even if it is an approximation!) to think that such a quite huge mass can be contained in such a small radius. Note that for the latter it corresponds to respectively a maximum density of:

$$\rho_{\text{max}} = \frac{1.4M_{\odot}}{\dfrac{4}{3}\pi R^3} \cong 15 \cdot 10^{14}\,[\text{kg} \cdot \text{mm}^{-3}] \tag{12.2.198}$$

12.2.1.3.3 Neutron Star Masses and Densities

If a nearly spherical star of mass M and radius R rotates with angular velocity $\omega = 2\pi/R$ we know obviously that we have then equilibrium of the centrifugal (fictional) force and gravitational bound a the equator at a given instant such that we are led to write (we make here an obvious classical approximation instead of using General Relativity that should be mandatory when dealing with huge masses):

$$\frac{v^2}{R} = \frac{GM}{R^2} \tag{12.2.199}$$

Hence:

$$\frac{(\omega R)^2}{R} = \frac{GM}{R^2} \tag{12.2.200}$$

After simplification:

$$\omega^2 R = \frac{GM}{R^2} \tag{12.2.201}$$

Implying:

$$\left(\frac{2\pi}{T}\right)^2 R = \frac{GM}{R^2} \tag{12.2.202}$$

Hence:

$$T^2 = \left(\frac{4\pi R^3}{3}\right)\frac{3\pi}{GM} \tag{12.2.203}$$

As the density of a ball is given by:

$$\rho = \frac{M}{\dfrac{4\pi R^3}{3}} \tag{12.2.204}$$

We then have:

$$T = \sqrt{\frac{3\pi}{G\rho}} \tag{12.2.205}$$

Hence:

$$\boxed{\rho = \frac{3\pi}{GT^2}} \tag{12.2.206}$$

That latter relation gives a conservative lower limit to the mean density because a rapidly spinning star is oblate, which increases the centrifugal (fictional) acceleration and decreases the gravitational acceleration at its equator.

The first pulsar discovered has a period of $T=1.3$ [s], so its mean density is at least:

$$\rho=\frac{3\pi}{GT^2}\cong 10^8\,[\text{g}\cdot\text{cm}^{-3}] \tag{12.2.207}$$

The fastest known pulsar actually (year 12018 according to holocene calendar), PSR J1748-2446ad, has $T=1.4\cdot 10^{-3}$ [s] implying $\rho>10^{14}$, the density of atomic nuclei!!!!! It has been calculated that this neutron star contains slightly less than two times the mass of the Sun, within the typical range of neutron stars. Its radius is constrained to be less than 16 [km]. At its equator it is spinning at approximately 24% of the speed of light, or over $70,000$ [km] per second!!!

12.2.1.3.4 Neutron Star magnetic field

As the star's core collapses, its rotation rate increases as a result of conservation of angular momentum, hence newly formed neutron stars rotate at up to several hundred times per second. Some neutron stars emit beams of electromagnetic radiation that make them detectable as pulsars. Indeed, the discovery of pulsars in 11967 (holocen calendar) was the first observational suggestion that neutron stars exist. The radiation from pulsars is thought to be primarily emitted from regions near their magnetic poles. If the magnetic poles do not coincide with the rotational axis of the neutron star, the emission beam will sweep the sky, and when seen from a distance, if the observer is somewhere in the path of the beam, it will appear as pulses of radiation coming from a fixed point in space (the so-called "lighthouse effect"). The fastest rotation rate for a neutron star was a rate of 716 times a second or $43,000$ revolutions per minute, giving a linear speed at the surface on the order of $0.165c$....

So now let us focus on the simplified math approach of the impact of the angular momentum conservation on the magnetic field of the star.

From the conservation of angular moment as the core collapses we have (see section Classical Mechanics page 3297):

$$J_i\omega_i=J_f\omega_f \tag{12.2.208}$$

Or, for a sphere of constant density (see section Geometric Shapes page 2968):

$$\frac{2}{5}M_iR_i^2\omega_i=\frac{2}{5}M_fR_f^2\omega_f \tag{12.2.209}$$

So the final spin frequency is:

$$\omega_f=\omega_i\left(\frac{R_i}{R_f}\right)^2 \tag{12.2.210}$$

or the final spin period is:

$$T_f=T_i\left(\frac{R_f}{R_i}\right)^2 \tag{12.2.211}$$

The magnetic flux Φ ($\vec{B}$ multiplied by S) through the surface of the core is also conserved in collapse. So roughly (see section Electrodynamics page 4100):

$$B_i 4\pi R_i^2 = B_f 4\pi R_f^2 = 0 \tag{12.2.212}$$

Which means that:

$$B_f = B_i \left(\frac{R_i}{R_f}\right)^2 \tag{12.2.213}$$

The Sun (actually a G2V-type star, aka yellow dwarf) and many other stars are known to possess approximately dipolar magnetic fields. Stellar interiors are fully ionized and hence good electrical conductors. Charged particles are constrained to move along magnetic field lines, and magnetic field lines are tied to the charged particles. When a star collapses from a radius $\sim 10^6$ [km] to ~ 10 [km], its cross-sectional area a is divided by $\sim 10^{10}$, its magnetic flux $\Phi \equiv \int \vec{B} \cdot \hat{n} \mathrm{d}a$ (where $\hat{n}$ is the unit vector normal to each infinitesimal surface area $\mathrm{d}a$) is conserved, and the magnetic field strength is multiplied by $\sim 10^{10}$. An initial magnetic field strength $B \sim 100$ [G] becomes $B \sim 10^{12}$ [G] after collapse, so young neutron stars should have very strong dipolar fields. The best models of the core-collapse process show that a dynamo effect can generate even stronger magnetic fields. Such dynamos may be able to produce the $10^{14} - 10^{15}$ [G] fields observed in magnetars, which are neutron stars having such strong magnetic fields that their radiation is powered by magnetic field decay. Conservation of angular momentum during collapse increases the rotation rate by about the same factor, 10^{10}, yielding initial rotation periods in the millisecond range.

12.2.1.3.5 Spin-Down Luminosity

If we now consider a neutron star as perfectly symmetric of radius $R = 10$ [km] it's moment of inertia will be equal to (see section Classical Mechanics page 3297):

$$J = \frac{2MR^2}{5} \cong \frac{2 \cdot 1.4 M_\odot \cdot (10^4)^2}{5} \cong 10^{38}\,[\mathrm{kg} \cdot \mathrm{m}^2] \tag{12.2.214}$$

The rotational kinetic energy (see section Classical Mechanics page 3297) of a canonical neutron star with the rotation period $T = 0.033$ [s] of the Crab pulsar is:

$$E_r = \frac{1}{2}\omega^2 J = \frac{2\pi^2 J}{T^2} \cong \frac{2\pi^2 \cdot 10^{38}}{0.033^2} \cong 1.8 \cdot 10^{42}\,[\mathrm{J}] \tag{12.2.215}$$

As magnetic dipole radiation extracts rotational energy, it slowly increases the period of a pulsar:

$$\dot{T} \equiv \frac{\mathrm{d}T}{\mathrm{d}t} > 0 \tag{12.2.216}$$

Note that the period derivative $\dot{T}$ is a dimensionless (seconds per second) pure number. Combining the observed period T and period derivative $\dot{T}$ yields an estimate of the rate $\dot{E}$ at which the rotational energy is changing. The quantity:

$$-\dot{E}_r \equiv -\frac{\mathrm{d}E_t}{\mathrm{d}t} = -\frac{\mathrm{d}}{\mathrm{d}t}\left(\frac{1}{2}J\Omega^2\right) = -J\Omega\dot{\Omega} \tag{12.2.217}$$

is named the "spin-down luminosity". It is not a measured luminosity; it is the measured loss rate of rotational energy, which is presumed to equal the luminosity of magnetic dipole radiation. The spin-down luminosity is usually expressed in terms of the pulse period T :

$$T=\frac{2\pi}{P} \quad \text{so} \quad \dot{\Omega}=2\pi\left(-T^{-2}\dot{T}\right) \tag{12.2.218}$$

and the prior-previous relation becomes:

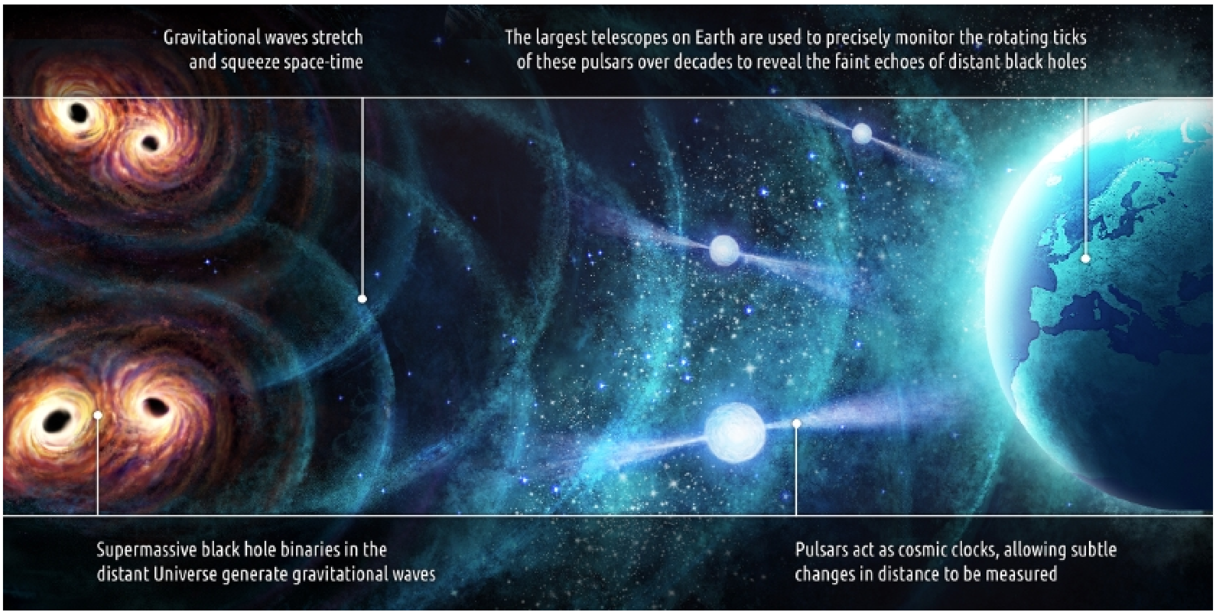
$$-\dot{E}_r=\frac{4\pi^2 J\dot{P}}{P^3} \tag{12.2.219}$$

The Crab pulsar has $T=0.033$ [s] and $\dot{T}=10^{-12.4}$ (notice that the precision is so that pulsars can be used as galactic GPS!). If $J=10^{38}$ $[\text{kg}\cdot\text{m}^2]$, its spin-down luminosity is:

$$-\dot{E}_r=\frac{4\pi^2 J\dot{P}}{P^3}=\frac{4\pi^2\cdot 10^{45}\,[\text{g}\cdot\text{cm}^2]\cdot 10^{-12.4}\,[\text{s}\cdot\text{s}^{-1}]}{(0.033\,[\text{s}])^3}\cong 4\cdot 10^{38}\,[\text{erg}\cdot\text{s}^{-1}]\cong 10^5 L_{\odot} \tag{12.2.220}$$

So the luminosity of the low frequency magnetic dipole radiation from the Crab pulsar is comparable with the entire radio output of our Galaxy...

Pulsar are in the early 121st century very useful as detectors of huge gravitational waves. This is what we name a "pulsar timing array" (PTA) that is a set of galactic pulsars that is monitored and analysed to search for correlated signatures in the pulse arrival times on Earth. As such, they are galactic-sized detectors. Although there are many applications for pulsar timing arrays, the best known is the use of an array of millisecond pulsars to detect and analyse long-wavelength (i.e., low-frequency) gravitational wave background and was proposed originally in the years 11970 by M.V. Sazhin and S.L. Detweiler.

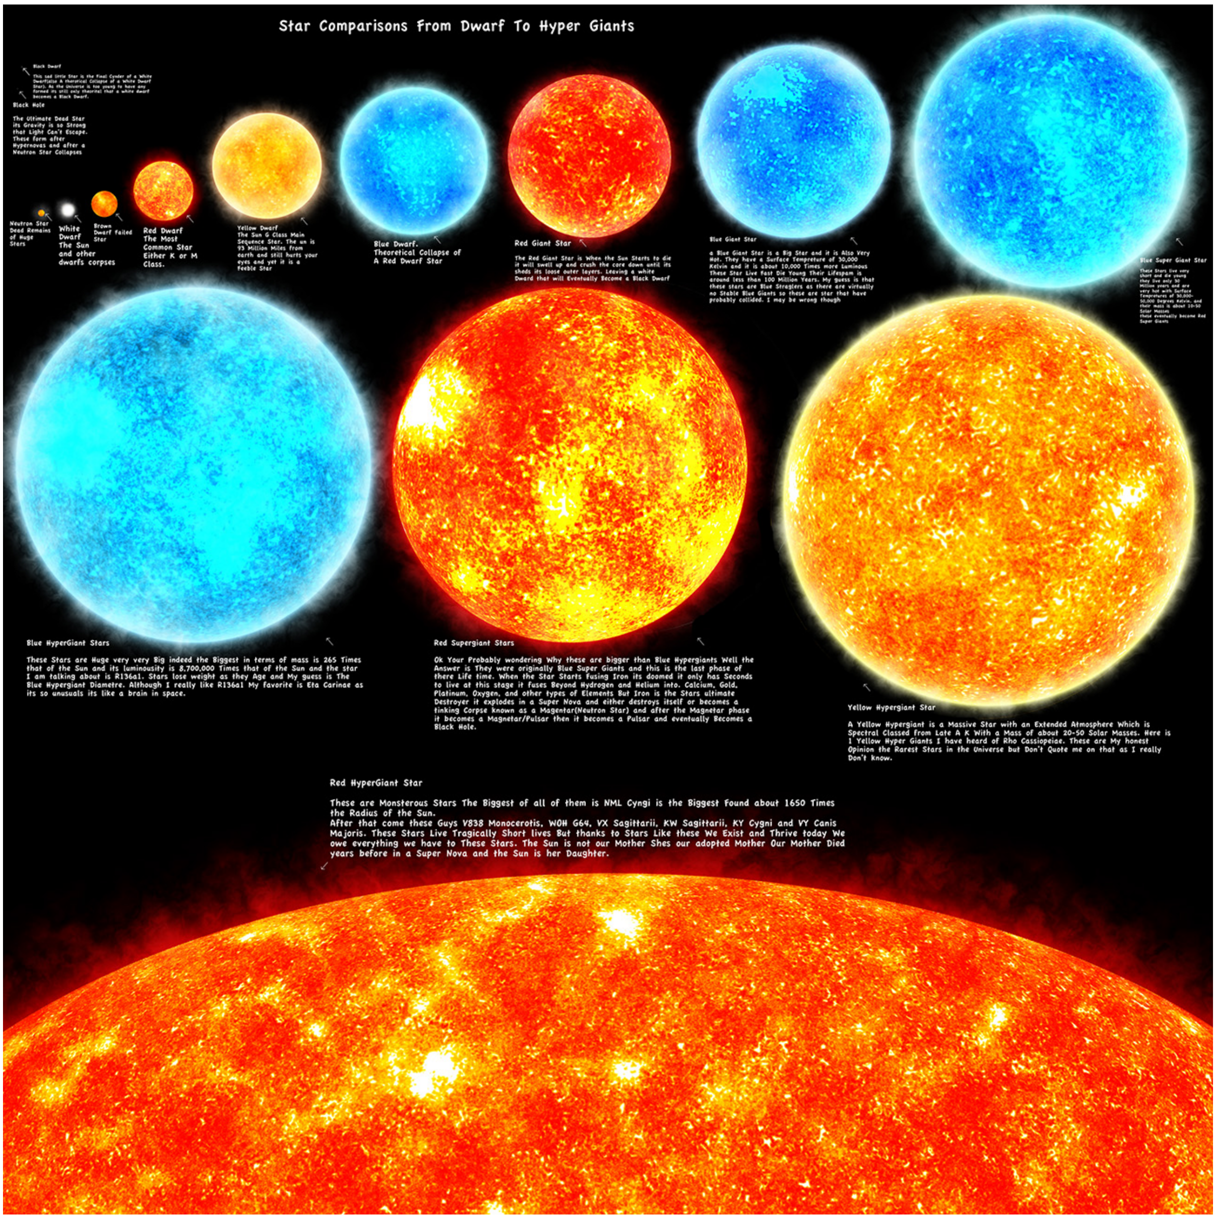


Gravitational waves stretch and squeeze space-time
The largest telescopes on Earth are used to precisely monitor the rotating ticks of these pulsars over decades to reveal the faint echoes of distant black holes
Supermassive black hole binaries in the distant Universe generate gravitational waves
Pulsars act as cosmic clocks, allowing subtle changes in distance to be measured

Figure 12.188: **Pulsar timing array artistic illustration (source: Forth Institute of Astrophysics)**

The European Pulsar Timing Array (EPTA) and Indian Pulsar Timing Array (InPTA) collaborations have measured a low-frequency common signal in the combination of their second and first data releases, respectively, with the correlation properties of a gravitational wave background (GWB). Such a signal may have its origin in a number of physical processes including a cosmic population of inspiralling supermassive black hole binaries (SMBHBs); inflation, phase transitions, cosmic strings, and tensor mode generation by the non-linear evolution of scalar perturbations in the early Universe; and oscillations of the Galactic potential in the presence of ultra-light dark matter (ULDM). At the current stage of emerging evidence, it is impossible to discriminate among the different origins. It has been found (see [20]) in 12024 (holocene calendar) that the signal is consistent with a cosmic population of inspiralling SMBHBs, and its relatively high amplitude can be used to place constraints on binary merger timescales and the SMBHhost galaxy scaling relations. If this origin is confirmed, this would be the first direct evidence that SMBHBs merge in nature, adding an important observational piece to the puzzle of structure formation and galaxy evolution. As for early Universe processes, the measurement would place tight constraints on the cosmic string tension and on the level of turbulence developed by first-order phase transitions. Other processes would require non-standard scenarios, such as a blue-tilted inflationary spectrum or an excess in the primordial spectrum of scalar perturbations at large wavenumbers. Finally, a ULDM origin of the detected signal is disfavoured, which leads to direct constraints on the abundance of ULDM in our Galaxy.

Arrived so far in the study of some very common stars models (excepted for Black Holes that are treated in the section of General Relativity page 5835) it is maybe the right time to introduce this summary image:



Star Comparisons From Dwarf To Hyper Giants

Black Dwarf

This sad little Star is the Final Cynder of a White Dwarf(also A theretical Collapse of a White Dwarf Star). As the Universe is too young to have any formed its still only theorital that a white dwarf becomes a Black Dwarf.

Black Hole

The Ultimate Dead Star its Gravity is so Strong that Light Can't Escape. These form after Hypernovas and after a Neutron Star Collapses

Neutron Star Dead Remains of Huge Stars

White Dwarf The Sun and other dwarfs corpses

Brown Dwarf Failed Star

Red Dwarf The Most Common Star Either K or M Class.

Yellow Dwarf The Sun G Class Main Sequence Star. The un is 93 Million Miles from earth and still hurts your eyes and yet it is a feeble Star

Blue Dwarf. Theoretical Collapse of A Red Dwarf Star

Red Giant Star

The Red Giant Star is When the Sun Starts to die it will swell up and crush the core down until its sheds its loose outer layers. Leaving a white Dward that will Eventually Become a Black Dwarf

Blue Giant Star

a Blue Giant Star is a Big Star and it is Also Very Hot. They have a Surface Tempreture of 30,000 Kelvin and it is about 10,000 Times more Luminous These Star Live Fast Die Young Their Lifespam is around less than 100 Million Years. My guess is that these stars are Blue Straglers as there are virtually no Stable Blue Giants so these are star that have probably collided. I may be wrong though

Blue Super Giant Star

These Stars live very short and die young they live only 50 Million years and are very hot with Surface Tempretures of 30,000-50,000 Degrees Kelvin, and their mass is about 10-50 Solar Masses these eventually become Red Super Giants

Blue HyperGiant Stars

These Stars are Huge very very Big indeed the Biggest in terms of mass is 265 Times that of the Sun and its luminousity is 8,700,000 Times that of the Sun and the star I am talking about is R136a1. Stars lose weight as they Age and My guess is The Blue Hypergiant Diametre. Although I really like R136a1 My favorite is Eta Carinae as its so unusuals its like a brain in space.

Red Supergiant Stars

Ok Your Probably wondering Why these are bigger than Blue Hypergiants Well the Answer is They were originally Blue Super Giants and this is the last phase of there Life time. When the Star Starts Fusing Iron its doomed it only has Seconds to live at this stage it fuses Beyond Hydrogen and Helium into. Calcium, Gold, Platinum, Oxygen, and other types of Elements But Iron is the Stars ultimate Destroyer it explodes in a Super Nova and either destroys itself or becomes a tinking Corpse known as a Magentar(Neutron Star) and after the Magnetar phase it becomes a Magnetar/Pulsar then it becomes a Pulsar and eventually Becomes a Black Hole.

Yellow Hypergiant Star

A Yellow Hypergiant is a Massive Star with an Extended Atmosphere Which is Spectral Classed from Late A K With a Mass of about 20-50 Solar Masses. Here is 1 Yellow Hyper Giants I have heard of Rho Cassiopeiae. These are My honest Opinion the Rarest Stars in the Universe but Don't Quote me on that as I really Don't know.

Red HyperGiant Star

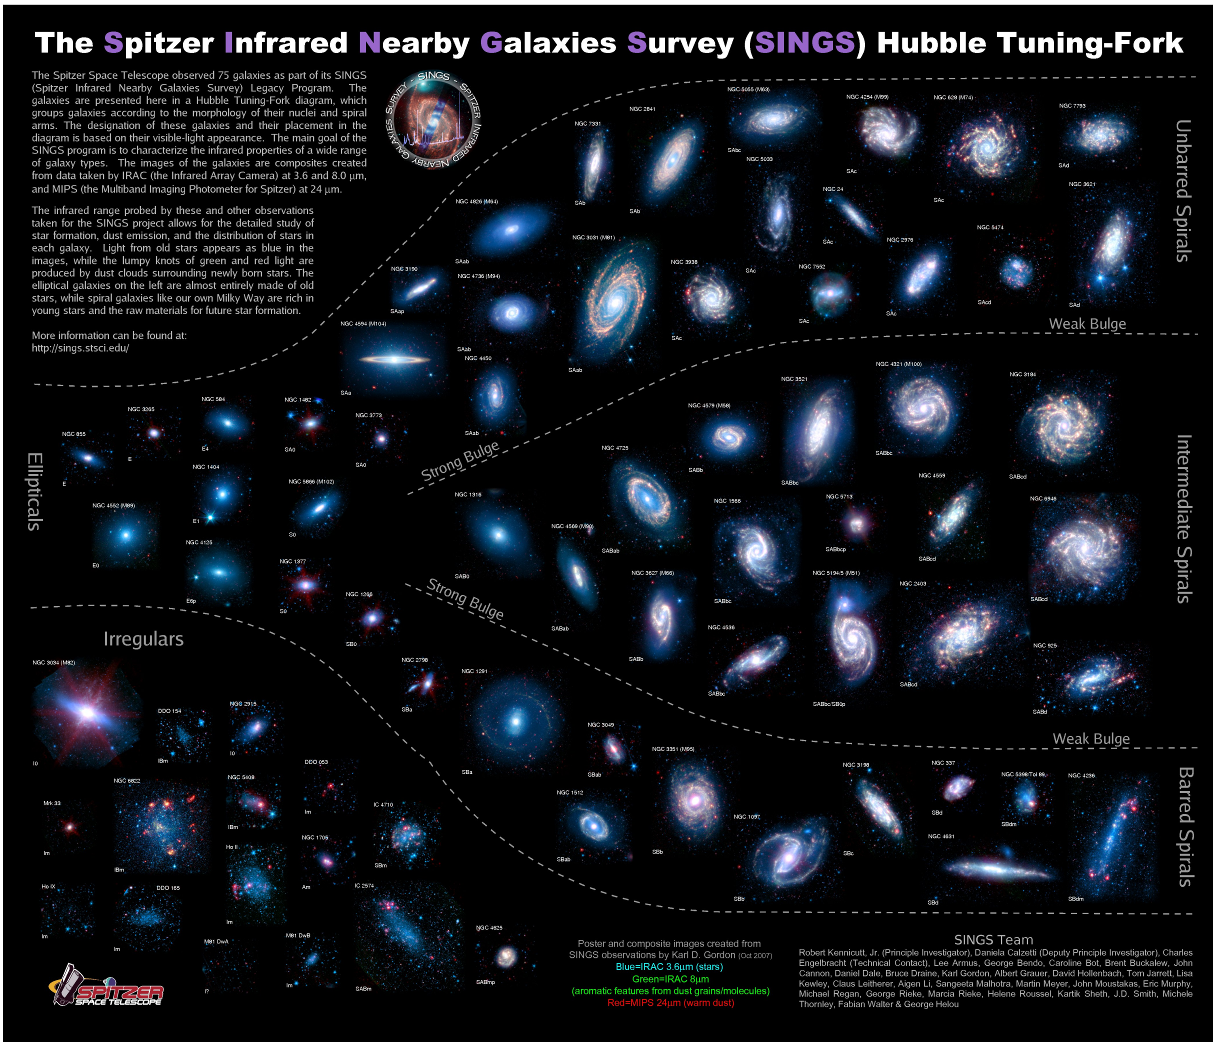
These are Monsterous Stars The Biggest of all of them is NML Cyngi is the Biggest Found about 1650 Times the Radius of the Sun.
After that come these Guys V838 Monocerotis, WOH G64, VX Sagittarii, KW Sagittarii, KY Cygni and VY Canis Majoris. These Stars Live Tragically Short lives But thanks to Stars Like these We Exist and Thrive today We owe everything we have to These Stars. The Sun is not our Mother Shes our adopted Mother Our Mother Died years before in a Super Nova and the Sun is her Daughter.

Figure 12.189: Star comparisons from Black Dwarf to hyper giants (author: Karl Garnham)

12.2.2 Galaxies

A galaxy is a gravitationally bound system of stars, stellar remnants, interstellar gas, dust, and dark matter[36].

Galaxies range in size from dwarfs with just a few billion (10^9) stars to giants with one hundred trillion (10^{14}) stars, each orbiting its galaxy's center of mass. Galaxies are categorized according to their visual morphology as elliptical, spiral or irregular:



The Spitzer Infrared Nearby Galaxies Survey (SINGS) Hubble Tuning-Fork

The Spitzer Space Telescope observed 75 galaxies as part of its SINGS (Spitzer Infrared Nearby Galaxies Survey) Legacy Program. The galaxies are presented here in a Hubble Tuning-Fork diagram, which groups galaxies according to the morphology of their nuclei and spiral arms. The designation of these galaxies and their placement in the diagram is based on their visible-light appearance. The main goal of the SINGS program is to characterize the infrared properties of a wide range of galaxy types. The images of the galaxies are composites created from data taken by IRAC (the Infrared Array Camera) at 3.6 and 8.0 µm, and MIPS (the Multiband Imaging Photometer for Spitzer) at 24 µm.

The infrared range probed by these and other observations taken for the SINGS project allows for the detailed study of star formation, dust emission, and the distribution of stars in each galaxy. Light from old stars appears as blue in the images, while the lumpy knots of green and red light are produced by dust clouds surrounding newly born stars. The elliptical galaxies on the left are almost entirely made of old stars, while spiral galaxies like our own Milky Way are rich in young stars and the raw materials for future star formation.

More information can be found at:
http://sings.stsci.edu/

Poster and composite images created from SINGS observations by Karl D. Gordon (Oct 2007)
Blue=IRAC 3.6µm (stars)
Green=IRAC 8µm

Smith, Michele Thornley, Fabian Walter & George Helou

Figure 12.190: **Apparent stars speed anomaly in galaxies rotations**

Many galaxies are thought to have Black Holes at their active centers.

It seems that there is between $2 \cdot 10^{11}$ galaxies in the observable Universe following the actual estimates in this early 121st century (holocene calendar). Most of the galaxies are $1,000$ to $100,000$ parsecs in diameter and usually separated by distances on the order of millions of parsecs (or megaparsecs). The space between galaxies is filled with a tenuous gas having an average density of less than one atom per cubic meter. The majority of galaxies are gravitationally organized into associations known as galaxy groups, clusters, and superclusters. At the largest scale, these associations are generally arranged into sheets and filaments surrounded by immense voids.

---

[36] Since June 12025 (holocene calendar) it is known thanks to FRB (Fast Radio Bursts) that approximately 76% of the Universe's baryonic matter lies in the IGM (InterGalactic Medium). About 15% resides in galaxy halos, and a small fraction is burrowed in stars or amid cold galactic galactic gas ([109]).

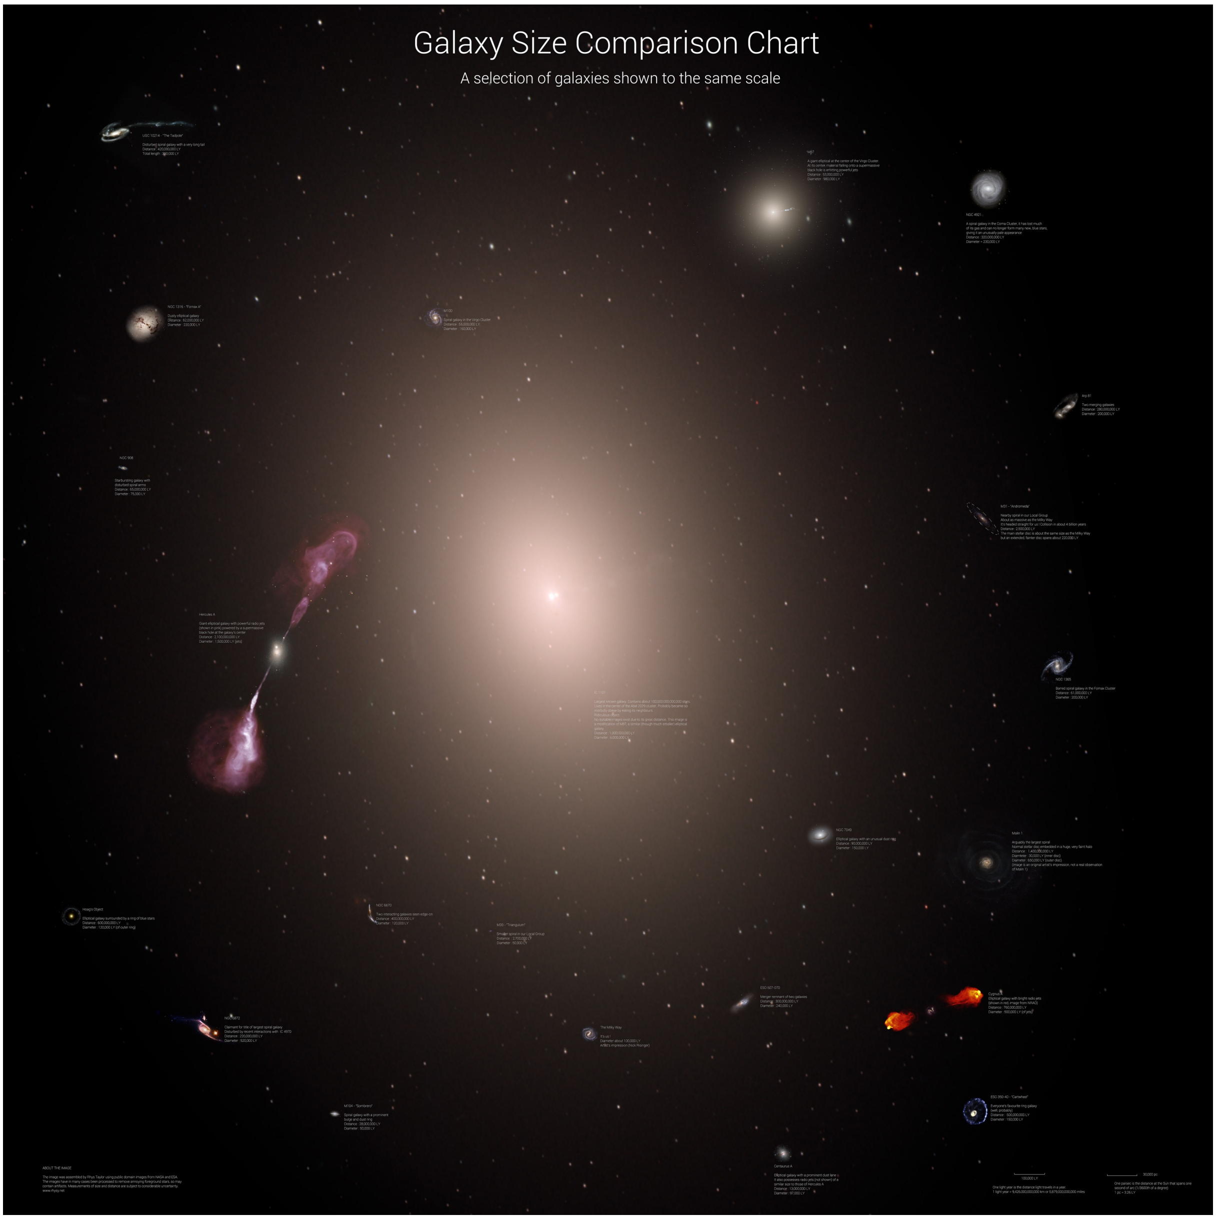
Size comparisons of some famous galaxies:



Galaxy Size Comparison Chart
A selection of galaxies shown to the same scale
UGC 10214 - "The Tadpole"
Disturbed spiral galaxy with a very long tail
Distance : 420,000,000 LY
Total length : 390,000 LY
M87
A giant elliptical at the center of the Virgo Cluster.
At its center, material falling onto a supermassive
black hole is emitting powerful jets
Distance : 53,000,000 LY
Diameter : 980,000 LY
NGC 4921
A spiral galaxy in the Coma Cluster, it has lost much
of its gas and can no longer form many new, blue stars,
giving it an unusually pale appearance
Distance : 320,000,000 LY
Diameter = 230,000 LY
NGC 1316 - "Fornax A"
Dusty elliptical galaxy
Distance : 62,000,000 LY
Diameter : 220,000 LY
M100
Spiral galaxy in the Virgo Cluster
Distance : 55,000,000 LY
Diameter : 160,000 LY
Arp 81
Two merging galaxies
Distance : 280,000,000 LY
Diameter : 200,000 LY
NGC 908
Starbursting galaxy with
disturbed spiral arms
Distance : 65,000,000 LY
Diameter : 75,000 LY
M31 - "Andromeda"
Nearby spiral in our Local Group
About as massive as the Milky Way
It's headed straight for us ! Collision in about 4 billion years
Distance : 2,500,000 LY
The main stellar disc is about the same size as the Milky Way
but an extended, fainter disc spans about 220,000 LY
Hercules A
Giant elliptical galaxy with powerful radio jets
(shown in pink) powered by a supermassive
black hole at the galaxy's center
Distance : 2,100,000,000 LY
Diameter : 1,500,000 LY (jets)
IC 1101
Largest known galaxy. Contains about 100,000,000,000,000 stars.
Lives in the center of the Abel 2029 cluster. Probably became so
morbidly obese by eating its neighbours.
Ridiculous object.
No suitable images exist due to its great distance. This image is
a modification of M87, a similar (though much smaller) elliptical
galaxy.
Distance : 1,000,000,000 LY
Diameter : 6,000,000 LY
NGC 1365
Barred spiral galaxy in the Fornax Cluster
Distance : 61,000,000 LY
Diameter : 200,000 LY
NGC 7049
Elliptical galaxy with an unusual dust ring
Distance : 90,000,000 LY
Diameter : 150,000 LY
Malin 1
Arguably the largest spiral
Normal stellar disc embedded in a huge, very faint halo
Distance : 1,400,000,000 LY
Diamteter : 30,000 LY (inner disc)
Diameter : 650,000 LY (outer disc)
(image is an original artist's impression, not a real observation
of Malin 1)
Hoag's Object
Elliptical galaxy surrounded by a ring of blue stars
Distance : 600,000,000 LY
Diameter : 120,000 LY (of outer ring)
NGC 6670
Two interacting galaxies seen edge-on
Distance : 400,000,000 LY
Diameter : 120,000 LY
M33 - "Triangulum"
Smaller spiral in our Local Group
Distance : 2,700,000 LY
Diameter : 50,000 LY
ESO 507-070
Merger remnant of two galaxies
Distance : 300,000,000 LY
Diameter : 240,000 LY
Cygnus A
Elliptical galaxy with bright radio jets
(shown in red, image from NRAO)
Distance : 760,000,000 LY
Diameter : 500,000 LY (of jets)
NGC 6872
Claimant for title of largest spiral galaxy
Disturbed by recent interactions with IC 4970
Distance : 220,000,000 LY
Diameter : 520,000 LY
The Milky Way
It's us !
Diameter about 100,000 LY
Artist's impression (Nick Risinger)
M104 - "Sombrero"
Spiral galaxy with a prominent
bulge and dust ring
Distance : 28,000,000 LY
Diameter : 50,000 LY
ESO 350-40 - "Cartwheel"
Everyone's favourite ring galaxy
(well, probably)
Distance : 500,000,000 LY
Diameter : 150,000 LY
Centaurus A
Elliptical galaxy with a prominent dust lane
It also possesses radio jets (not shown) of a
similar size to those of Hercules A
Distance : 13,000,000 LY
Diameter : 97,000 LY
ABOUT THE IMAGE
The image was assembled by Rhys Taylor using public domain images from NASA and ESA.
The images have in many cases been processed to remove annoying foreground stars, so may
contain artifacts. Measurements of size and distance are subject to considerable uncertainty.
www.rhysy.net
100,000 LY
One light year is the distance light travels in a year.
1 light year = 9,426,000,000,000 km or 5,879,000,000,000 miles
30,000 pc
One parsec is the distance at the Sun that spans one
second of arc (1/3600th of a degree)
1 pc = 3.26 LY

Figure 12.192: Size comparisons of famous galaxies (author: Rhys Taylor)

12.2.2.1 Probability of collisions in merging galaxies

Stars collide with each other very rarely. The distance between neighbouring stars (at our position in the Milky Way Galaxy) is approximately equal to 10 million times the diameter of a star. By contrast, galaxies collide with each other quite frequently. The distance between neighbouring galaxies is approximately equal to 20 times the diameter of a galaxy.

To illustrate this difference, consider building a scale model of our Galaxy in which the stars are represented by ping-pong balls. In this model, the distance between the Sun and Alpha Centauri will be 1, 100 kilometres (the distance between Columbus and Jacksonville, Florida). Now consider a scale model of the universe in which individual galaxies are represented by ping-pong balls. In this model, the Milky Way Galaxy and the Andromeda Galaxy will be a pair of ping-pong balls only 1 meter apart.

Let's see what we get from some back-of-the-envelope estimates.

Imagine throwing one star (e.g., the Sun) at the other galaxy. How likely is it we'll hit a star in the other galaxy? Well, it's basically proportional to how big a target each star in the other galaxy is (its cross-sectional area) compared to the size of the whole galaxy, multiplied by the total number of stars in the target galaxy.

Let's assume it's the Milky Way-Andromeda scenario, so each galaxy has about 100 billion stars, and each star is roughly the same size as the Sun (some are much larger, most are smaller). The actual target area for an individual star is a circle with twice the star's radius (we're counting one star just grazing the other as a collision). Let's also assume the stars are more or less evenly distributed in a circular disk. Since "$100,000$ light years" is a common (and not completely crazy) estimate of the Milky Way's size, that's a circle of radius $=50,000$ light years (about 10^{16} meters).

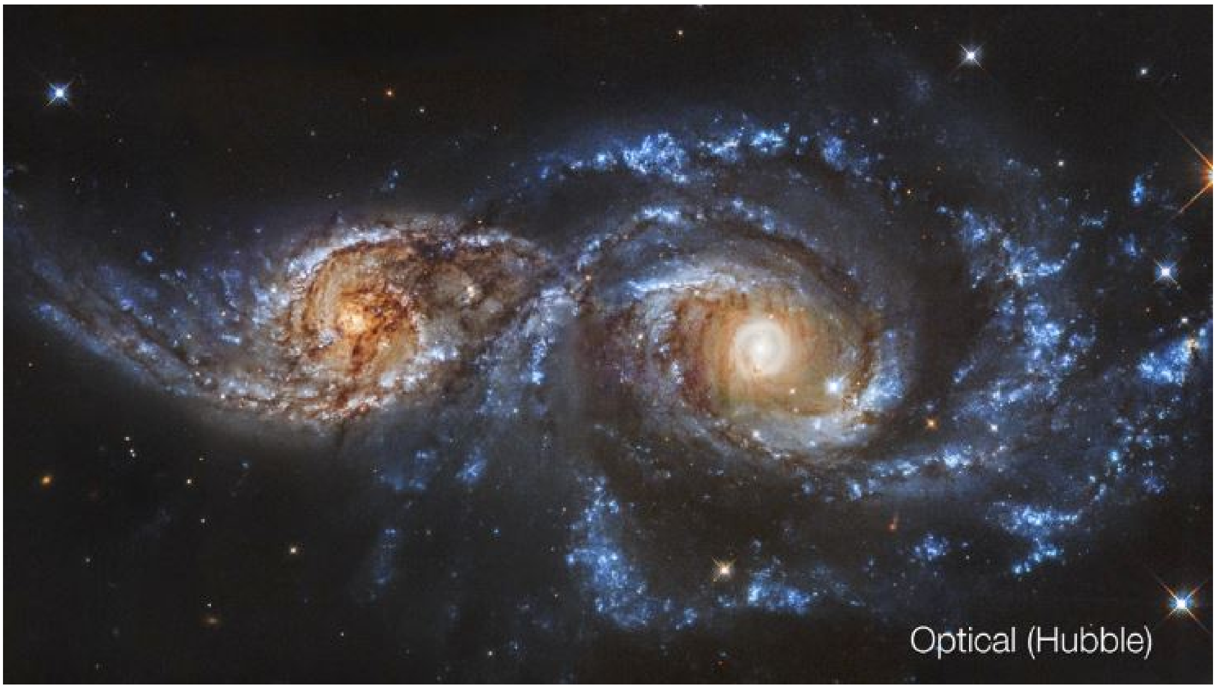


Figure 12.193: **NGC 2207 is a pair of colliding spiral galaxies (source: NASA/Hubble)**

So, let us consider two galaxies as perfect discs of 100 billion (10^{11}) stars uniformly distributed in the disc going in the target galaxy, each with target average radius $\sim 2R_\odot$, gives us a total target area of:

$$S_{T,\text{stars}} \cong 10^{11}\cdot\pi(2R_\odot)^2 \approx 10^{30}\;[\text{m}^2] \qquad (12.2.221)$$

The cross-section area of the target galaxy is:

$$S_{\text{gal.}} \cong \pi R_{\text{gal.}}^2 \approx 10^{42}\;[\text{m}^2] \qquad (12.2.222)$$

Therefore the probability of a typical average star hitting another star in the other galaxy is :

$$P_{\text{coll.}} \cong \frac{10^{30}}{10^{42}} = 10^{-12} \qquad (12.2.223)$$

or about one in a trillion.

The odds of any star from our Galaxy not hitting a star in the other galaxy would be:

$$(1-10^{-12})^{10^{11}} \cong 0.90 \tag{12.2.224}$$

So there's only about a 10% chance of one (or more) of the galaxy's 100 billion stars hitting a star in the other galaxy. And the chances of any one particular star (like our Sun) hitting a star in the other galaxy is about one in a trillion.

Remark

Obviously we could use the binomial law to get the probability (or cumulated probability depending on what we want) that k among N start would get hit:

$$\mathcal{B}(N,k)=\binom{N}{k}p^k q^{N-k}=\frac{N!}{k!(N-k)!}p^k q^{N-k} \tag{12.2.225}$$

or as the probabilities are very small and the population huge we could even use a Poisson distribution instead!

12.2.2.2 Radial Speed Anomaly

In 11978 (holocene calendar), Vera Rubin begins to observe that in galaxies, more the stars are distant from the galactic core, the more their angular velocity is high... The initial observation that uniformity of speed was unexpected because the theory of gravity Newton predicted that more distant objects have less speed. For example, the planets of the Solar System orbit with a respective speed decreases while growing their respective distance from the Sun. We are left with the same problem: how to explain a point measurement is greater than the theoretical value?

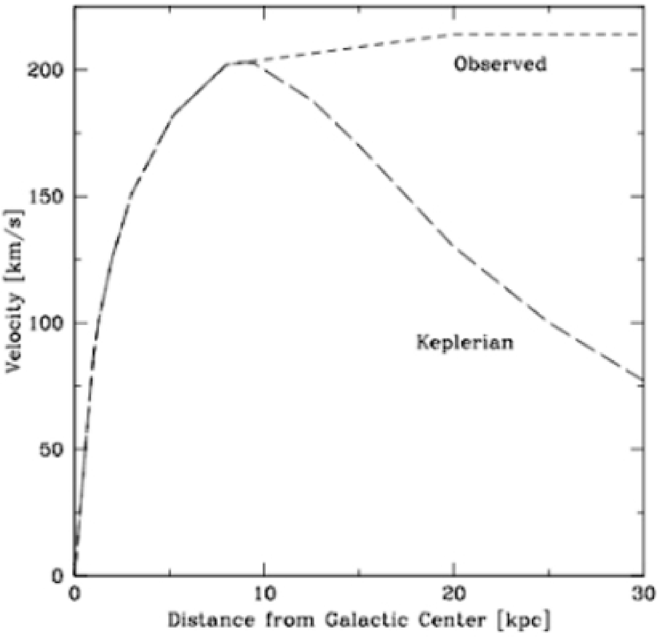

Figure 12.194: Apparent stars speed anomaly in galaxies rotations

According to Newton's laws, in a circular path, there is a as we know balance between the centripetal acceleration and gravitational attraction:

$$a=\frac{v^2}{r}=\frac{GM}{r^2} \tag{12.2.226}$$

The volume of a disk galaxy of radius R and thickness e is (see section Geometric Shapes page 2959):

$$V=\pi R^2 e \tag{12.2.227}$$

If we consider the mass of the galaxy almost entirely within the radius R_{max}, corresponding to the maximum speed, of density ρ is given then by:

$$M=\pi R_{\text{max}}^2 e\rho \tag{12.2.228}$$

Making the approximation that the mass is substantially within the range corresponding to the maximum speed, we can write:

$$r\cong R_{\text{max}}=\sqrt{\frac{M}{\pi e\rho}} \tag{12.2.229}$$

Which, introduced into the first equation but rearranged:

$$v=\sqrt{\frac{GM}{r}} \tag{12.2.230}$$

gives:

$$v=\sqrt{\frac{GM}{\sqrt{\dfrac{M}{\pi e\rho}}}}=\sqrt{G}\,(M\pi e\rho)^{1/4} \tag{12.2.231}$$

the law that the maximum speed varies as the $1/4$ power of the mass. After that the speed decrease of the stars should decrease following:

$$v=\sqrt{\frac{GM}{r}} \tag{12.2.232}$$

But we must keep in mind that this is a two body relation! In the facts a galaxy should be considered as an isotropic fluid (like the rest of the universe) and therefore it is quite normal that the two-body assumption does not suit the observations. A galaxy can also not be consider as a solid cylinder otherwise by applying $v=\omega r$ the speed of the stars should increase in proportion to the distance to the center of the galaxy. For a more rigorous treatment of the topic the reader should refer to the page 5284.

12.3. Special Relativity

We have always considered until now in all our developments that the interactions (causes and effects) between objects were instantaneous and that the observation of a phenomenon took place therefore instantly after it had occurred. However two physicists, Michelson and Morley (see [390]), during an experiment in 11887 (holocene calendar) discovered something that would change radically all of classical physics: the velocity (speed) of light was invariant (constant) regardless of the movement that we had relatively to it (and another type of experiment that leads to the same conclusion was done later by De Sitter as described in his paper [133] among many others)!

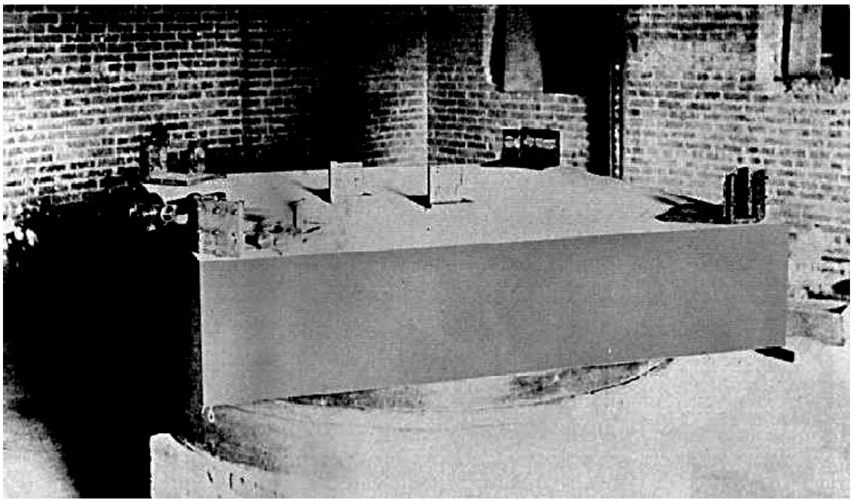

Figure 12.195: Michelson and Morley's original interferometric setup, mounted on a stone slab that floats in an annular trough of mercury (source: Case Western Reserve University)

This observation is even more important that we know it is mainly the light that allows us to perceive and feel things around us! It should also be taken into consideration that the electrostatic and magnetic fields are, as we have seen in the section of Quantum Field Theory, carried by the vector of interaction that is the photon that moves at the finite speed of light denoted by c. This fact also allows us to assume that the gravitational field also has an interaction vector (which would be the "graviton" whose existence seems indirectly proven but not yet confirmed still in this early 121st century according to holocene calendar) that propagates at the speed of light. It is therefore appropriate to take into account this non-immediacy and the consequences that this entails in the observed phenomena to finally be able to decide what is really of what seems to be.

Before we start with the calculations, we need to define a little bit what will be studied in this section (which applies not only to cosmology but... it seemed to us better to put it in this chapter rather than in the chapter of Mechanics or Atomistic).

Definition (#12.3.540): "Special Relativity" is a scientific theory confined to isolated inertial frames (Galileans), that is to say, the study of animated frames in a uniform (inertial) rectilinear motion. The reason of this will be given in the statement of Special Relativity principle (see below).

Remarks

R1. Restrict the study to inertial frames of course does not does not prohibit that within these, bodies can be animated of a uniform speed or not (an inertial rocket can have bodies inside itself that have a non-uniform movement)!

R2. General Relativity's purpose (see corresponding section at page 5720) is to take into account non-inertial frames and in any coordinate system by making use of the power of the tensor calculus to be applicable in any type of space (other than flat one!).

Special Relativity is mainly based on three important concepts:

1. The invariance postulate of speed of light
2. The cosmological principle (see below)
3. The principle of Special Relativity (see below)

It is also important to inform the reader that we will use here many concepts seen in the section of Linear Algebra, Tensor Calculus, Trigonometry, Analytical Mechanics, Classical Mechanics, Electrostatics, Magnetostatics and Electrodynamics. It is therefore strongly advised to have covered these topics before at risk of not understanding what follows.

12.3.1 Assumptions and Principles

Physics laws express relations between the fundamental physical quantities. If the laws of physics are invariant under Galilean referential change as we have seen in the section of Classical Mechanics, it is not necessarily the same for physical quantities! These can transform from Galilean frame to another according to simple transformation law as we have seen in the section of Classical Mechanics for velocity for example. It is the same in Special Relativity, but we must now consider what we neglected in our study of Galileo's transformations: the time lag is not the same for two observers if the speed of the light is finite, but the concept of time interval is supposed to be kept invariant!

12.3.1.1 Postulate of Invariance

Laboratory measurements (Michelson-Morley experiment as we have already mentioned) have, for a long time, shown that the speed c measured in an inertial frame (straight line and at constant speed) is constant regardless of its speed. Then we are taken to state the postulate of invariance of light: the speed of light (vector for the transport of photons) can neither be added nor subtracted, to the drive speed of the frame in which we measure it (more clearly it means that no matter how fast you move, you will always measure the speed of light as being numerically finite and equal to $c=299,792,458\,[\text{km}\cdot\text{s}^{-1}]$!).

As corollary the principle of Galilean relativity (see section Classical Mechanics page 3239) according to this premise is completely at fault and then we have to develop a new theory that takes into account of this property of light.

Remark

It is important to notice that we consider that light, within the framework of Special Relativity, the messenger of information from one body to another, that is to say the speed of causality effect!!!

On Internet Forums a common and interesting question is: *Why is there a limit speed for causality and for the speed of light?*

First, if the light speed would be infinite, we would not have light at all! Indeed, to see this, take a look at Maxwell's equations again, Note that in them we have the factor:

$$c=\frac{1}{\sqrt{\mu_0\varepsilon_0}} \tag{12.3.1}$$

so if we set $c\rightarrow+\infty$ then either (or both) of μ_0 and ε_0 would have to be zero. This will effectively kill the existence of dynamic magnetic fields.

Especially, for light, it means that:

$$\vec{\nabla}\times\vec{B}=\frac{1}{c^2}\frac{\partial\vec{E}}{\partial t}\rightarrow 0 \tag{12.3.2}$$

So, magnetic fields would be static (and of zero intensity, remember no magnetic monopoles known so far!). Thus the only thing left of electromagnetism would be simply electrostatics. Physically this also make sense, if $c\rightarrow+\infty$ the electric field response to any rearrangement of charges would be instantaneous, so there is no place (time?) for a magnetic field response.

The existence of the speed limit for causality is related to the existence of time itself. Indeed, if there would be no speed limit, everything would happen instantly (as well as distance and consequently space by the way). It is difficult to imagine a Universe that evolve instantaneously. This is why we belong to a Universe where there is a speed limit otherwise we would very likely not be here to observe it...

12.3.1.2 Cosmological Principle

We assume that our position in the Universe is typical not only in space as stated in the standard model of the Universe (see section Cosmogony page 5881), but also in time. Thus, an astronomer located in a remote galaxy must observe the same general properties of the Universe that we do whatever he lived a billion years ago or that he observed the Universe in a billion years in the future!

In fact, it is quite natural to go further and state that: the Universe looks the same in every point, that is to say, it is homogeneous. This homogeneity is therefore sets as the "Cosmological Principle".

This principle is not based, still actually in this early 121st century (holocene calendar), on experimental data because they are too much fragmentary compared to the huge size of the cosmos (very likely infinite). Therefore we are not able yet to establish its validity (there are two publications based on a huge amount of observations of our Hubble sphere and one of the both paper is a preprint that contradicts the conclusion of the first one... see [522] and [480]). It constitutes however a presupposition for any physical study of our Universe. Its purpose is relative to its character, essential to any scientific cosmology study, and perhaps to a certain reaction to the geocentric or heliocentric old vision: it is assumed now that no place is special in the cosmos!

For an in-deep discussion and criticism of the subject based on the earliest experimental data (of this early 121st century according to holocene calendar), the reader can refer to the excellent 100 pages paper *Is the observable Universe consistent with the cosmological principle?* (see [15]).

12.3.1.3 Special Relativity Principle

Let us remind (see section Classical Mechanics page 3239) that the Galilean transformations tell us that no reference frames can be considered as an absolute frame because the relations between the physical quantities are identical in all Galilean repositories ("Galilean relativity principle"). The Galilean motion is therefore relative!

In the 120th century (holocene calendar) physicists noted that an important class of physical phenomena violated the Galilean relativity principle: the electromagnetic phenomena!

By applying the Galilean transformations to Maxwell's equations, we get a different set of equations depending on whether the observer is in a fixed reference or a mobile reference frame.

Indeed, we have proved in the section on Electrodynamics that the electric or magnetic field propagation equation could be written in one-dimensional space as the following d'Alembert equation (see page 4118):

$$\left(\frac{\partial^2}{\partial x^2}-\frac{1}{c^2}\frac{\partial^2}{\partial t^2}\right)\psi=0 \tag{12.3.3}$$

where ψ represents any one of the two fields (electric or magnetic). We name this relation sometimes "Hertz equation".

We also saw in the section of Classical Mechanics (see page 3239) that an important factor in the validity of a theory is the invariance of the expression of its laws under a Galilean transformation by putting:

$$x'=x-u_xt,y'=y,z'=z,t'=t \tag{12.3.4}$$

We have also shown in the section of Differential and Integral Calculus (see page 1466) that the total differential of a function was written (example with two variables):

$$\mathrm{d}f(x',y')=\frac{\partial}{\partial x'}\mathrm{d}x'+\frac{\partial}{\partial y'}\mathrm{d}y' \tag{12.3.5}$$

Therefore:

$$\mathrm{d}f(x',t')=\frac{\partial f}{\partial x'}\mathrm{d}x'+\frac{\partial f}{\partial t'}\mathrm{d}t' \tag{12.3.6}$$

Which brings us to simply write (using the physicist method way of life...):

$$\frac{\partial f}{\partial x}=\frac{1}{\partial x}\frac{\partial f}{\partial x'}\mathrm{d}x'+\frac{1}{\partial x}\frac{\partial f}{\partial t'}\mathrm{d}t' \tag{12.3.7}$$

After elimination of f and using the Schwarz theorem (see section Differential and Integral Calculus page 1469) and still the physicist way of life:

$$\begin{aligned}\frac{\partial}{\partial x}&=\frac{1}{\partial x}\frac{\partial}{\partial x'}\mathrm{d}x'+\frac{1}{\partial x}\frac{\partial}{\partial t'}\mathrm{d}t'=\frac{\partial}{\partial x'}\frac{\partial x'}{\partial x}+\frac{\partial}{\partial t'}\frac{\partial t'}{\partial t}\\&=\frac{\partial}{\partial x'}\frac{\partial(x-u_xt)}{\partial x}+\frac{\partial}{\partial t'}\frac{\partial t'}{\partial t}=\frac{\partial}{\partial x'}1+\frac{\partial}{\partial t'}0=\frac{\partial}{\partial x'}\end{aligned} \tag{12.3.8}$$

If we write the same with the time variable:

$$\begin{aligned}\frac{\partial}{\partial t}&=\frac{1}{\partial t}\frac{\partial}{\partial x'}\mathrm{d}x'+\frac{1}{\partial t}\frac{\partial}{\partial t'}\mathrm{d}t'=\frac{\partial}{\partial x'}\frac{\partial x'}{\partial t}+\frac{\partial}{\partial t'}\frac{\partial t'}{\partial t}\\&=\frac{\partial}{\partial x'}\frac{\partial(x-u_xt)}{\partial t}+\frac{\partial}{\partial t}\frac{\partial t'}{\partial t'}=\frac{\partial}{\partial x'}(-u_x)+\frac{\partial}{\partial t'}1=-u_x\frac{\partial}{\partial x'}+\frac{\partial}{\partial t'}\end{aligned} \tag{12.3.9}$$

Ultimately the Galilean transformation of the wave equation supposedly have an invariant form becomes:

$$\left(\frac{\partial^2}{\partial x'^2}-\frac{1}{c^2}\left(-u_x\frac{\partial}{\partial x'}+\frac{\partial}{\partial t'}\right)^2\right)\psi=\left(\frac{\partial^2}{\partial x'^2}-\frac{u_x^2}{c^2}\frac{\partial^2}{\partial x'^2}+2\frac{u_x}{c^2}\frac{\partial^2}{\partial x'\partial t}-\frac{1}{c^2}\frac{\partial^2}{\partial t'^2}\right)\psi=0 \tag{12.3.10}$$

To fix the situation, following this example, we can state at least three assumptions:

H1. Maxwell's equations are false. The correct equations remain to be discovered and must be invariant under a Galilean transformation.

H2. Galilean invariance is valid for mechanics but not for electromagnetism (that was the historical solution before Albert Einstein: an "ether" determines the existence of a kind of absolute repository where Maxwell's equations didn't change).

H3. Galilean invariance is false. There is a more general invariance, it remains to be discovered, which preserves the form of the Maxwell equations. Classical mechanics is to be reformulated so that it is invariant under this new transformation.

Remark

It turns out that the first two assumptions are excluded by the experimental facts. Moreover, Maxwell's equations integrating the speed of light they are implicitly relativistic.

Albert Einstein did not accept the violation of the Galilean relativity principle by electromagnetism. From his perspective, it was necessary to generalize it to all natural laws.

He postulated that the laws of physics should be the same in all repositories Galileans, which means, implicitly, that in the point of view of physical laws, it is not possible to distinguish one from another Galilean frame. This result is most commonly formulated as: no reference is privileged. This principle was named "principle of relativity". Indeed, this relativity is restricted to the case of Galileans frames (also named "inertial frames") exclusively.

In other words, the physic laws should remain unchanged after a change of reference. We must therefore identify new adequate transformations that will substitute to the Galilean transformations.

In the case of non Galileans frames repositories are not indistinguishable anymore. Indeed, imagine a person in a train moving at a constant speed and another person on land. Everyone can then say that it is the other who is in motion (relative) and indiscriminately. By cons, if the train begins to accelerate, although the two individuals can say that this is another speeding, only the one on the train will feel the effect of this acceleration ... and repositories are no more indistinguishable.

Albert Einstein abolished as well as the idea that there is an absolute reference point that does not move and on which we can define an absolute time, an absolute length or absolute mass. However, one can define a privileged reference point for every object in the Universe. It is the frame moving at the same speed and in the same direction as the object. The time measured in this privileged reference frame is minimal and is named the "proper time". Similarly, the size of the object is maximum, it is his "proper dimension" or "proper distance", and its mass is minimal, it is its "proper mass" (we will do the corresponding detailed mathematical developments further below).

Remark

Albert Einstein did share the credit with Hendrik Lorentz and Henri Poincaré for Special Relativity for a while, probably one reason his Nobel prize did not mention relativity. Because Lorentz in 11904 according to holocene calendar (who misinterpreted his own transformations as applying to the Ether) laid the fundamentals for the work by Einstein, this theory was originally named the "Lorentz–Einstein theory". Poincaré struggled with his own proof of $E=3/4mc^2$ and improved Lorentz transformation formulation (June 5, 11905 according to holocene calendar). Einstein at the very least gets credit for being the first to correctly interpret the equations and do away with the Ether concept and get the correct relation $E=mc^2$ (June 30, 11905 according to holocene calendar).

12.3.2 Lorentz Transformations/Boost

For make possible to c to be invariant (light speed invariance postulate), we must admit that time appears to not flow the same way for the observer O that is motionless than for the observer O$'$ in a reference frame in uniform translation (i.e.: an inertial frame) in the direction of x with relative velocity (the term "relative" is important!) v (caution! the relative speed between the repositories is often denoted in the literature by u).

Remark

A special case of disposal of referential frames in which the space axes are parallel leads to what we name the "pure Lorentz transformations" or "special Lorentz transformations" and the relative displacement along a particular axis is often named a "boost".

To study the behaviour of physic laws, we must bring two clocks that give the times t and t' (the referential frame that contains its clock/measuring instrument is named "proper referential" or "proper frame").

Let's set up the following imaginary experiment:

When the observers O and O' are superimposed, we set $t=0$ and $t'=0$ (clock time sync) and we emit a bright flash[37] in the direction of a point A spotted by respectively $\vec{r}$ and $\vec{r}'$:

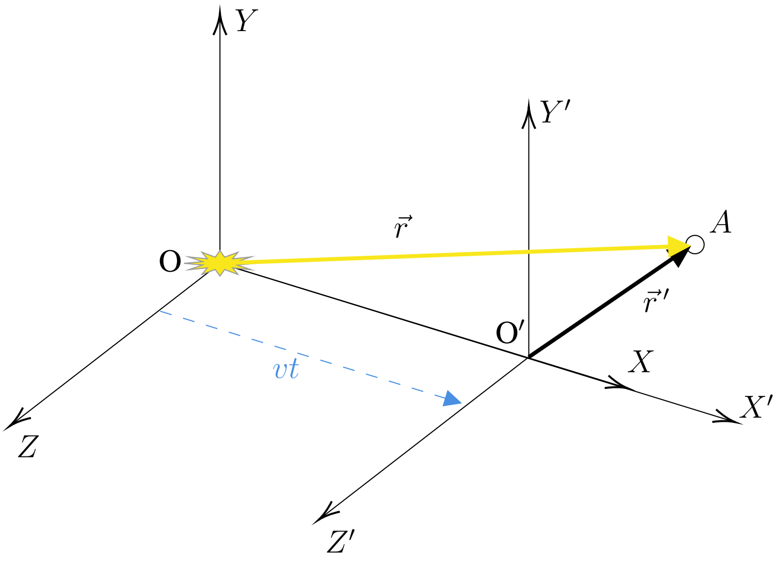

Figure 12.196: **Configuration for the study of relativistic effects**

It is obvious that when the flash arrives in A, the observer O will measure a time t and O$'$ a time t'.

The observer O therefore concludes:

$$r=ct=\sqrt{x^2+y^2+z^2}\Rightarrow x^2+y^2+z^2=c^2t^2 \tag{12.3.11}$$

---

[37] In fact we should consider the emission of "an element of information". Using light as an example is just convenient for pedagogical purposes. As we will see the results we will get further below involve a speed limit c that is for sure the speed of light, but in reality we should consider light as a special case of the maximum possible speed of information transfer. The "c" can then be seen as the "causality speed".

The observer O$'$ therefore concludes:

$$r'=ct'=\sqrt{x'^2+y'^2+z'^2}\Rightarrow x'^2+y'^2+z'^2=c^2t'^2 \tag{12.3.12}$$

Since the displacement of O$'$ is made only along the Ox axis, we have for the two observers:

$$y=y',z=z' \tag{12.3.13}$$

Moreover, if the path of the light beam coincides within the axe Ox, we have:

$$y=y'=0,z=z'=0 \tag{12.3.14}$$

This gives us then:

$$x^2=c^2t^2,x'^2=c^2t'^2 \tag{12.3.15}$$

And therefore:

$$x^2-c^2t^2=0,x'^2-c^2t'^2=0 \tag{12.3.16}$$

these two relations are equal (zero) at any x,x',t,t' between the two observers. These are the first "relativistic invariant" (equal values regardless of the frame), especially here is about the "invariant interval" also named "space-time interval", that we find in a more generalized form when applied to the whole space:

$$\boxed{x^2+y^2+z^2-c^2t^2=x'^2+y'^2+z'^2-c^2t'^2=0} \tag{12.3.17}$$

Now it should be remembered that in the classical point of view (Galilean relativity), we would have written that the position of point A for the observer O from the information given by O$'$ would be given by $x=x'+vt$ and vice versa (see section Classical Mechanics page 3239) such as:

$$x'=x-vt'=x-vt \tag{12.3.18}$$

However.... in the relativistic model, we must admit that time t which is related to x is not the same as t' which is related to x', relativity principle oblige (otherwise it would be difficult to explain the invariance of the speed of light)!

We are then led to try to write the above relation as follows:

$$x'=\lambda(x-vt) \tag{12.3.19}$$

where λ would be a numerical value to be determined from a given algebraic expression. Because to explain the constancy of the speed of light one possibility is that the space must constantly adjust according to our velocity v. What is revolutionary hypothesis as we have already mentioned!

Remark

A reader asked us why we could not write the last relation in the following simplified form (using the relation $x=ct$ obtained above) where point A is on the X axis:

$$x'=\lambda(x-vt)=\lambda\left(x-v\frac{x}{c}\right)=\lambda x\left(1-\frac{v}{c}\right) \tag{12.3.20}$$

The only reason is that later we will introduce a vector (matrix) notation of this result showing the concept of quadrivector (four-vector) and that it is in the first form of writing (this making explicit reference to time) that we can clearly make the concept of space-time emerge.

Furthermore, if $t\neq t'$, we must also be able to express t' as a function of t and x in a similar way:

$$t'=a(t-bx) \tag{12.3.21}$$

Let us summarize the shape of the problem:

$$x'=\lambda(x-vt) \tag{12.3.22}$$

with λ to be determined and after:

$$t'=a(t-bx) \tag{12.3.23}$$

with a,b to be determined. We then seek to determine the relation that gives us to know the values of the coefficients a,b and λ that satisfy simultaneously:

$$x^2+y^2+z^2=c^2t^2 \qquad x'^2+y'^2+z'^2=c^2t'^2 \tag{12.3.24}$$

Remembering the previous developments and bearing in mind that in our special case $y'=y$ and $z'=z$, the last equation becomes:

$$\lambda^2(x-vt)^2+y^2+z^2=c^2a^2(t-bx)^2 \tag{12.3.25}$$

Let us distribute:

$$(\lambda^2-a^2b^2c^2)x^2-2(\lambda^2v-ba^2c^2)xt+y^2+z^2=\left(a^2-\frac{\lambda^2v^2}{c^2}\right)c^2t^2 \tag{12.3.26}$$

To satisfy the relation:

$$x^2+y^2+z^2=c^2t^2 \tag{12.3.27}$$

We must have:

$$\begin{aligned}\lambda^2-b^2a^2c^2&=1 \quad (1)\\ \lambda^2v-ba^2c^2&=0 \quad (2)\\ a^2-\frac{\lambda^2v^2}{c^2}&=1 \quad (3)\end{aligned} \tag{12.3.28}$$

It is easy to solve (2):

$$\lambda^2=\frac{ba^2c^2}{v} \tag{12.3.29}$$

We then introduce this result in (1) and (3) and we arrive at:

$$\begin{aligned} \lambda^2-a^2b^2c^2&=\frac{ba^2c^2}{v}(1-bv)=1 \quad (1') \\ a^2-\frac{\lambda^2v^2}{c^2}&=a^2(1-bv)=1 \qquad (2') \end{aligned} \tag{12.3.30}$$

If we divide (1') by (2'), we get:

$$\frac{c^2b}{v}=1\Rightarrow b=\frac{v}{c^2} \tag{12.3.31}$$

and introducing this latter result into the relation:

$$a^2(1-bv)=1 \tag{12.3.32}$$

we obtain the following remarkable result:

$$a=\frac{1}{\sqrt{1-\dfrac{v^2}{c^2}}} \tag{12.3.33}$$

That we frequently denote by:

$$\boxed{a=\frac{1}{\sqrt{1-\dfrac{v^2}{c^2}}}=\frac{1}{\sqrt{1-\beta^2}}} \tag{12.3.34}$$

and which we name "Michelson-Morley factor" with:

$$\boxed{\beta=\frac{v}{c}} \tag{12.3.35}$$

Also introducing:

$$b=\frac{v}{c^2} \tag{12.3.36}$$

in:

$$\lambda^2=\frac{ba^2c^2}{v} \tag{12.3.37}$$

we get:

$$\lambda=a=\frac{1}{\sqrt{1-\left(\dfrac{v}{c}\right)^2}} \tag{12.3.38}$$

Let us denote now (to comply with the traditional notations in this field):

$$\gamma=\frac{1}{\sqrt{1-\beta^2}} \tag{12.3.39}$$

named the "Lorentz factor" with therefore the parameter:

$$\beta=\frac{v}{c}\leq 1 \tag{12.3.40}$$

that doesn't have any name as far as we know...

Caution! The "Lorentz transformations" are sadly sometimes interpreted by scientifically illiterate people and undergraduate students as a physical transformation. But it is not! It's just a mathematical transformation to explain what one reference frame sees in comparison of another one. Nothing more!

12.3.2.1 Displacement four-vector

We just derived the "Lorentz transformation" relations to pass from the values measured by O$'$ to those measured in O and vice versa[38]:

$$\begin{aligned} x'&=\gamma(x-vt) & x&=\gamma(x'+vt')\\ y'&=y & y&=y'\\ z'&=z & z&=z'\\ t'&=\gamma\left(t-\frac{v}{c^2}x\right) & t&=\gamma\left(t'+\frac{v}{c^2}x'\right) \end{aligned} \tag{12.3.41}$$

That have for property to be covariant (that is to say their relations keep the same structure during a change of a Galilean reference system). We see through these relations that the concept of "time" is something individual relating to the movement we have over other (this is the "proper time"). This is why it is not possible to define a "common time" between two people moving relatively and who don't know their respective relative speed (and even here we do not take into account the gravity that distorts space-time ... that we will study in the section of General Relativity).

Remark

If v is much smaller than c, we fall back on the Galilean transformation as $\gamma\cong 1$ and $v/c^2\cong 0$

We can also write the last relations in a more useful way (the reader will notice that this time that for all relations the units of all the terms to the left of equality are the same: it is every time a distance!):

$$\begin{aligned} x&=\gamma(x'+\beta ct')\\ y&=y'\\ z&=z'\\ ct&=\gamma\left(ct'+\beta x'\right) \end{aligned} \tag{12.3.42}$$

---

[38] Such relations were first written by Woldemart Voigt in 11887 (holocene calendar). Between 11892 (holocene calendar) and 11902 (holocene calendar) by trial and errors Hendrik Lorentz will improve the shape of these relations. In 11905 (holocene calendar) Poincaré confirmed and corrected Lorent'z work of 11904 (holocene calendar) and give them their definitive shape.

Of course the difference is that the fourth dimension being the time coordinate of "space-time" seems at the contrary of the spatial coordinates to have a privileged direction: the "arrow of time" (you can not go back to a given moment time given in the reality - as least as far as we know today - when it is possible when we traverse a purely spatial distance). The direction of time is imposed by the second law of thermodynamics as entropy can only increase (see section Thermodynamics page 3658). If this were not the case then all time could already exist and we could travel in time as we travel on distances and therefore the future should be already written (people that believe in destiny like this...) and we could also go back in time.... However, thermodynamics does not give a particular direction to the time ... so if our time has the direction it has today.... it is because our universe was organized at its beginning (so it had a low entropy).

By proceeding in a homogenisation of units to be able to use more modern and generalized maths than just simple algebra we can see that in fact when we travel in time we travel in physical point of view a distance ct. But because c and t are measured in arbitrary human being units physicists prefer to put $c=1$ we mathematical development become more complicate rather than changing the definition of time.

Now we can put the Lorentz transformations of coordinate and time in the traditional following matrix form (see section Linear Algebra page 1924) which defines the "Lorentz matrix" or "Lorentz-Poincare matrix" or "Lorentz boost":

$$\begin{pmatrix} ct \\ x \\ y \\ z \end{pmatrix}=\begin{bmatrix} \gamma & \gamma\beta & 0 & 0 \\ \gamma\beta & \gamma & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix}\begin{pmatrix} ct' \\ x' \\ y' \\ z' \end{pmatrix} \tag{12.3.43}$$

and reciprocally (note that the time component ct is interchangeable with the space component x):

$$\begin{pmatrix} ct' \\ x' \\ y' \\ z' \end{pmatrix}=\begin{bmatrix} \gamma & -\gamma\beta & 0 & 0 \\ -\gamma\beta & \gamma & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix}\begin{pmatrix} ct \\ x \\ y \\ z \end{pmatrix} \tag{12.3.44}$$

and the reader can very easily control that with the two previous relations we fall back on:

$$\begin{aligned} x' &= \gamma(x-vt) & x &= \gamma(x'+vt') \\ y' &= y & y &= y' \\ z' &= z & z &= z' \\ t' &= \gamma\left(t-\frac{v}{c^2}x\right) & t &= \gamma\left(t'+\frac{v}{c^2}x'\right) \end{aligned} \tag{12.3.45}$$

We have also obviously:

$$\begin{aligned} \begin{bmatrix} \gamma & -\gamma\beta & 0 & 0 \\ -\gamma\beta & \gamma & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix}\begin{bmatrix} \gamma & \gamma\beta & 0 & 0 \\ \gamma\beta & \gamma & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} &= \begin{bmatrix} \gamma^2-\gamma^2\beta^2 & 0 & 0 & 0 \\ 0 & \gamma^2-\gamma^2\beta^2 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \\ &= \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \end{aligned} \tag{12.3.46}$$

In index form the matrix formulation is written:

$$\begin{pmatrix} x'_0 \\ x'_1 \\ x'_2 \\ x'_3 \end{pmatrix} = \begin{bmatrix} \gamma & -\gamma\beta & 0 & 0 \\ -\gamma\beta & \gamma & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \begin{pmatrix} x_0 \\ x_1 \\ x_2 \\ x_3 \end{pmatrix} \tag{12.3.47}$$

which can therefore be written in tensor (see section Tensor Calculus page 2039) form:

$$\boxed{x'^{\mu} = L^{\mu}_{\nu} x^{\nu}} \qquad \text{and} \qquad \boxed{x^{\nu} = L'^{\nu}_{\mu} x'^{\mu}} \tag{12.3.48}$$

Remark

We can see the tensor (the matrix) of Lorentz transformation in some books in the condensed form $L(\beta)$ and sometimes L^{μ}_{ν} or even Λ^{μ}_{ν}.

The vector:

$$x^{\mu} = (ct, x, y, z) = (ct, \vec{x}) \tag{12.3.49}$$

is named "space-time four-vector" or "four-vector displacement".

Notice that since:

$$x^2 + y^2 + z^2 - c^2t^2 = x'^2 + y'^2 + z'^2 - c^2t'^2 \tag{12.3.50}$$

the transformation by the matrix L^{μ}_{ν} conserves the norm (Lorentz invariance). In geometric terms it is thus a "isometry" or an invariance of the dot product by Lorentz transformation.

Let us prove this explicitly following the request of a reader! We will take again for the proof only a movement along x and we use:

$$\begin{aligned} x' &= \gamma(x - vt) & x &= \gamma(x' + vt') \\ y' &= y & y &= y' \\ z' &= z & z &= z' \\ t' &= \gamma\left(t - \frac{v}{c^2}x\right) & t &= \gamma\left(t' + \frac{v}{c^2}x'\right) \end{aligned} \tag{12.3.51}$$

As $y' = y$ and $z' = z$ to simplify the development we will ignore these both components.

$$\begin{aligned} x' &= \gamma(x - vt) & x &= \gamma(x' + vt') \\ t' &= \gamma\left(t - \frac{v}{c^2}x\right) & t &= \gamma\left(t' + \frac{v}{c^2}x'\right) \end{aligned} \tag{12.3.52}$$

We will also put to simplify $c = 1$ and therefore v is expressed in percentage of c and becomes $v = \beta$:

$$\begin{aligned} x' &= \gamma(x - \beta t) & x &= \gamma(x' + \beta t') \\ t' &= \gamma(t - \beta x) & t &= \gamma(t' + \beta x') \end{aligned} \tag{12.3.53}$$

Now we calculate:

$$\begin{aligned} x'^2 - t'^2 &= \gamma^2(x - \beta t)^2 - \gamma^2(t - \beta x)^2 \\ &= \gamma^2\left((x - \beta t)^2 - (t - \beta x)^2\right) = \gamma^2\left(x^2 - 2\beta tx + \beta^2t^2 - t^2 + 2\beta xt - \beta^2x^2\right) \\ &= \gamma^2\left(x^2 + \beta^2t^2 - t^2 - \beta^2x^2\right) = \gamma^2(1 - \beta^2)x^2 - \gamma^2(1 - \beta^2)t^2 \end{aligned} \tag{12.3.54}$$

and as $\gamma^2(1 - \beta^2) = 1$ we get indeed:

$$x'^2 - t'^2 = x^2 - t^2 \tag{12.3.55}$$

12.3.2.1.1 Wave Equation Invariance

Now that we have determined the Lorentz transformations, we can check whether the wave equation is invariant with respect to the latter (remember that we have proven earlier that it was not invariant under a Galilean transformation!!!).

Starting from the Lorentz transformation written in explicitly:

$$\begin{aligned}x'&=\gamma(x-vt)\\t'&=\gamma\left(t-\frac{v}{c^2}x\right)\end{aligned}\tag{12.3.56}$$

we calculate the partial derivatives with respect to x and t (the expression after the second equality has already been proven earlier in this section):

$$\begin{aligned}\frac{\partial}{\partial x}&=\frac{\partial}{\partial x'}\frac{\partial x'}{\partial x}+\frac{\partial}{\partial t'}\frac{\partial t'}{\partial x}=\gamma\frac{\partial}{\partial x'}-\gamma\frac{v}{c^2}\frac{\partial}{\partial t'}\\\frac{\partial}{\partial t}&=\frac{\partial}{\partial x'}\frac{\partial x'}{\partial t}+\frac{\partial}{\partial t'}\frac{\partial t'}{\partial t}=\gamma v\frac{\partial}{\partial x'}-\gamma\frac{\partial}{\partial t'}\end{aligned}\tag{12.3.57}$$

These relation can also be written:

$$\begin{aligned}c\frac{\partial}{\partial x}&=\gamma\left(c\frac{\partial}{\partial x'}-\beta\frac{\partial}{\partial t'}\right)\\\frac{\partial}{\partial t}&=-\gamma\left(v\frac{\partial}{\partial x'}-\frac{\partial}{\partial t'}\right)\end{aligned}\tag{12.3.58}$$

Squared:

$$\begin{aligned}c^2\frac{\partial^2}{\partial x^2}&=\gamma^2\left(c^2\frac{\partial^2}{\partial x'^2}-2\beta c\frac{\partial^2}{\partial x'\partial t'}+\beta^2\frac{\partial^2}{\partial t'^2}\right)\\\frac{\partial^2}{\partial t^2}&=\gamma^2\left(v^2\frac{\partial^2}{\partial x'^2}-2v\frac{\partial^2}{\partial x'\partial t'}+\frac{\partial^2}{\partial t'^2}\right)\end{aligned}\tag{12.3.59}$$

In the Maxwell's equations, or rather in the propagation equation of the electric or magnetic field in vacuum, we have proven (see section Electrodynamics page 4138) that the following operator appeared:

$$\frac{\partial^2}{\partial t^2}-c^2\frac{\partial^2}{\partial x^2}\tag{12.3.60}$$

Substituting in it the previous differential expressions:

$$\begin{aligned}\frac{\partial^2}{\partial t^2}-c^2\frac{\partial}{\partial x^2}&=\gamma^2\left(v^2\frac{\partial^2}{\partial x'^2}-2v\frac{\partial^2}{\partial x'\partial t'}+\frac{\partial}{\partial t'^2}-c^2\frac{\partial^2}{\partial x'^2}+2\beta c\frac{\partial^2}{\partial x'\partial t'}-\beta^2\frac{\partial^2}{\partial t'^2}\right)\\&=\gamma^2\left[-c^2\left(1-\frac{v^2}{c^2}\right)\frac{\partial^2}{\partial x'^2}-2v\frac{\partial^2}{\partial x'\partial t'}+2\beta c\frac{\partial^2}{\partial x'\partial t'}+(1-\beta^2)\frac{\partial^2}{\partial t'^2}\right]\\&=\frac{\partial}{\partial t'^2}-c^2\frac{\partial}{\partial x'^2}+2\gamma^2\left[-v\frac{\partial^2}{\partial x'\partial t'}+\frac{v}{c}c\frac{\partial^2}{\partial x'\partial t'}\right]=\frac{\partial}{\partial t'^2}-c^2\frac{\partial^2}{\partial x'^2}\end{aligned}\tag{12.3.61}$$

We therefore have well:

$$\frac{\partial^2}{\partial t^2}-c^2\frac{\partial^2}{\partial x^2}=\frac{\partial^2}{\partial t'^2}-c^2\frac{\partial^2}{\partial x'^2}\tag{12.3.62}$$

which shows that a Lorentz transformation leaves invariant this operator (Jackpot!). So we got what we were looking for (the wave equation but in the other reference frame)!

The reader will also have noticed that this only works if and only if the wave propagation speed is the speed of light!

12.3.2.1.2 Hypergeometric interpretation

Now let us come back to our Lorentz transformations. Let us recall that we have restricted ourselves to the special case where the space axes were parallel (what brought us to define the "pure Lorentz transformations"). This special configuration has an interesting geometric property that sometimes many books use.

Let us see what this is about:

We have seen in the context of the study of the Lorentz transformations of lengths that we had a special transformation (boost) along one axis, i.e. the x-axis, requiring in this case for the other components:

$$y'=y \qquad z'=z \tag{12.3.63}$$

This allows us to reduce the transformation matrix L_ν^μ (4×4 matrix that we obtained earlier above) to a 2×2 matrix of components A, B, C and D such that:

$$\begin{pmatrix} ct' \\ x' \end{pmatrix}=\begin{bmatrix} A & B \\ C & D \end{bmatrix}=\begin{pmatrix} ct \\ x \end{pmatrix} \tag{12.3.64}$$

We notice that the components A, B, C, D respect by construction the following expressions:

$$\begin{aligned}
A^2-C^2&=\gamma^2-(-\gamma\beta)^2=\gamma^2-\gamma^2\beta^2=\gamma^2(1-\beta^2)=\frac{1-\beta^2}{1-\beta^2}=1\\
D^2-B^2&=\gamma^2-(-\gamma\beta)^2=\gamma^2-\gamma^2\beta^2=\gamma^2(1-\beta^2)=\frac{1-\beta^2}{1-\beta^2}=1\\
AB-CD&=\gamma(-\gamma\beta)-\gamma(-\gamma\beta)=-\gamma^2\beta+\gamma^2\beta=0
\end{aligned} \tag{12.3.65}$$

The first relation can be related with the remarkable identity in hyperbolic trigonometry (see section Trigonometry page 2532):

$$\cosh^2(\theta)-\sinh^2(\theta)=1 \tag{12.3.66}$$

And therefore:

$$A=\cosh(\alpha_1) \quad \text{and} \quad C=-\sinh(\alpha_2) \tag{12.3.67}$$

and the second relation that there exists α_2 such that:

$$D=\cosh(\alpha_2) \quad \text{and} \quad B=-\sinh(\alpha_2) \tag{12.3.68}$$

Remark

The choice of the "$-$" sign for B and C is useful because as we always have $\beta \geq 0$ (same for γ that is strictly positive) it will impose us at the end of the calculations to have $\alpha \geq 0$. Therefore, as $-\gamma\beta \leq 0$ and $\alpha \geq 0$ the only way for C (and also for B) to be negative is to put a "$-$" sign.

The third then gives the remarkable addition relation:

$$AB - CD = -\cosh(\alpha_1)\sinh(\alpha_2) + \sinh(\alpha_1)\cosh(\alpha_2) = \sinh(\alpha_1 - \alpha_2) = 0 \tag{12.3.69}$$

and therefore the difference $\alpha_1 - \alpha_2$, that we will denote more simply by α, is equal zero. Which validates the relations:

$$A = D \Leftrightarrow \cosh(\alpha_1) = \cosh(\alpha_2) \qquad B = C \Leftrightarrow -\sinh(\alpha_2) = -\sinh(\alpha_1) \tag{12.3.70}$$

The matrix is therefore presented as follow:

$$L_{\nu}^{\mu} = \begin{bmatrix} \cosh(\alpha_1) & -\sinh(\alpha_1) \\ -\sinh(\alpha_1) & \cosh(\alpha_1) \end{bmatrix} = \begin{bmatrix} \cosh(\alpha_2) & -\sinh(\alpha_2) \\ -\sinh(\alpha_2) & \cosh(\alpha_2) \end{bmatrix} \tag{12.3.71}$$

This is (by analogy to the classical one) a "hyperbolic rotation matrix". We will not go further on this analogy as it is not used for practical cases study in this textbook.

Finally, the special Lorentz transformation of velocity v along the x-axis can also be written:

$$\begin{aligned} ct' &= \gamma(ct - \beta x) = \cosh(\alpha)ct - \sinh(\alpha)x = \cosh(\alpha)\left(ct - \frac{\sinh(x)}{\cosh(x)}x\right) \\ &= \cosh(\alpha)(ct - \tanh(\alpha)x) \\ x' &= \gamma(x - \beta ct) = \cosh(\alpha)x - \sinh(\alpha)ct = \cosh(\alpha)\left(x - \frac{\sinh(x)}{\cosh(x)}ct\right) \\ &= \cosh(\alpha)(x - \tanh(\alpha)ct) \end{aligned} \tag{12.3.72}$$

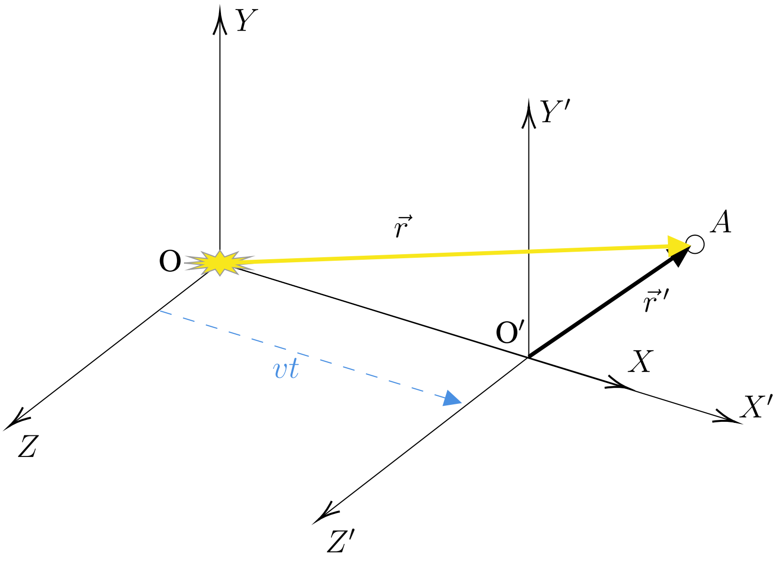
which brings us to write:

$$\beta = \frac{v}{c} = \tanh(\alpha) = \frac{\sinh(\alpha)}{\cosh(\alpha)} \qquad \text{and} \qquad \gamma = \frac{1}{\sqrt{1-\beta^2}} = \cosh(\alpha) \tag{12.3.73}$$

The dimensionless quantity α is named "rapidity" by those who use physics in high energy. The advantage of working with angles is to make the combination of 2 boosts easier.

12.3.2.2 Velocity four-vector

We can also determine the Lorentz transformations for speed. Let us consider again a particle moving in an inertial reference frame O' such that at time t', its coordinates are (x', y', z').:



Therefore, the components of the velocity v' are:

$$v'_x=\frac{\mathrm{d}x'}{\mathrm{d}t'},v'_y=\frac{\mathrm{d}y'}{\mathrm{d}t'},v'_z=\frac{\mathrm{d}z'}{\mathrm{d}t'} \tag{12.3.74}$$

So what are the components of the velocity in O (remember that O′ go away at speed v!)?

Again, we write:

$$v_x=\frac{\mathrm{d}x}{\mathrm{d}t},v_y=\frac{\mathrm{d}y}{\mathrm{d}t},v_z=\frac{\mathrm{d}z}{\mathrm{d}t} \tag{12.3.75}$$

We can differentiate by the time the components of the transformation equations we obtained before and thus we can write:

$$\begin{aligned}\mathrm{d}x&=\gamma(\mathrm{d}x'+(\beta c)\mathrm{d}t')\\ \mathrm{d}y&=\mathrm{d}y'\\ \mathrm{d}z&=\mathrm{d}z'\\ \mathrm{d}t&=\gamma\left(\mathrm{d}t'+\frac{\beta}{c}\mathrm{d}x'\right)\end{aligned} \tag{12.3.76}$$

Therefore we have:

$$v_z=\frac{\mathrm{d}z}{\mathrm{d}t}=\frac{\mathrm{d}z'}{\gamma\left(\mathrm{d}t'+\dfrac{\beta}{c}\mathrm{d}x'\right)}=\frac{\mathrm{d}z'}{\gamma\left(1+\dfrac{\beta}{c}v'_{x'}\right)\mathrm{d}t'}=\frac{v'_{z'}}{\gamma\left(1+\dfrac{\beta}{c}v'_{x'}\right)} \tag{12.3.77}$$

and also :

$$v_y=\frac{v'_{y'}}{\gamma\left(1+\dfrac{\beta}{c}v'_{x'}\right)} \tag{12.3.78}$$

and:

$$v_x=\frac{\mathrm{d}x}{\mathrm{d}t}=\frac{\gamma(\mathrm{d}x'+(\beta c)\mathrm{d}t')}{\gamma\left(\mathrm{d}t'+\dfrac{\beta}{c}\mathrm{d}x'\right)}=\frac{(v'_{x'}+(\beta c)\mathrm{d}t'}{\left(1+\dfrac{\beta}{c}v'_{x'}\right)\mathrm{d}t'}=\frac{v'_{x'}+\beta c}{1+\dfrac{\beta}{c}v'_{x'}} \tag{12.3.79}$$

And as the constant speed of reference frame O$'$ is given by $\beta = v/c$, we then have:

$$\boxed{v_x = \frac{v'_{x'} + v}{1 + \dfrac{v}{c^2} v'_{x'}}, v_y = \frac{v'_{y'}}{\gamma \left(1 + \dfrac{v}{c^2} v'_{x'}\right)}, v_z = \frac{v'_{z'}}{\gamma \left(1 + \dfrac{v}{c^2} v'_{x'}\right)}} \tag{12.3.80}$$

and vice versa:

$$\boxed{v'_{x'} = \frac{v_x + v}{1 + \dfrac{v}{c^2} v_x}, v'_{y'} = \frac{v_y}{\gamma \left(1 + \dfrac{v}{c^2} v_x\right)}, v'_{z'} = \frac{v_z}{\gamma \left(1 + \dfrac{v}{c^2} v_x\right)}} \tag{12.3.81}$$

Within the limit of classical mechanics, where the speed of light was supposed instantaneous and therefore $c \rightarrow +\infty$, we fall back on:

$$v_x = v'_{x'} + v, v_y = v'_{y'}, v_z = v'_{z'} \tag{12.3.82}$$

which are the Galilean transformations such as we have seen them in the section of Classical Mechanics.

As we can see, the speeds transformations do not follow too much the shape of the Lorentz matrix that we determined above for the coordinates. Physicists, not liking what is inhomogeneous, sought to have the same transformations for both.

Thus, let us take again the speed transformations and let us rewrite them as below:

$$\frac{v_x}{c} = \frac{\dfrac{v'_{x'}}{c} + \beta}{1 + \beta \dfrac{v'_{x'}}{c}}, \frac{v_y}{c} = \frac{\dfrac{v'_{y'}}{c}}{\gamma \left(1 + \beta \dfrac{v'_{x'}}{c}\right)}, \frac{v_z}{c} = \frac{\dfrac{v'_{z'}}{c}}{\gamma \left(1 + \beta \dfrac{v'_{x'}}{c}\right)} \tag{12.3.83}$$

These relation can be written differently if we calculate:

$$1 - \frac{\|\vec{v}\|^2}{c^2} = 1 - \frac{v_x^2 + v_y^2 + v_z^2}{c^2} = 1 - \left(\frac{\dfrac{v'_{x'}}{c} + \beta}{1 + \beta \dfrac{v'_{x'}}{c}}\right)^2 - \left(1 - \frac{v^2}{c^2}\right) \left(\left(\frac{\dfrac{v'_{y'}}{c}}{1 + \beta \dfrac{v'_{x'}}{c}}\right)^2 + \left(\frac{\dfrac{v'_{z'}}{c}}{1 + \beta \dfrac{v'_{x'}}{c}}\right)^2 \right) \tag{12.3.84}$$

Thus simplifying a bit:

$$\begin{aligned}
&\left(1 - \frac{\|\vec{v}\|^2}{c^2}\right) \left(1 + \beta \frac{v'_{x'}}{c}\right)^2 = \left(1 + \beta \frac{v'_{x'}}{c}\right)^2 - \left(\frac{v'_{x'}}{c} + \beta\right)^2 - \left(1 - \frac{v^2}{c^2}\right) \left(\left(\frac{v'_{y'}}{c}\right)^2 + \left(\frac{v'_{z'}}{c}\right)^2 \right) \\
&= 1 + 2\beta \frac{v'_{x'}}{c} + \beta^2 \left(\frac{v'_{x'}}{c}\right)^2 - \left(\frac{v'_{x'}}{c}\right)^2 - 2\beta \frac{v'_{x'}}{c} - \beta^2 - \left(1 - \frac{v^2}{c^2}\right) \left(\left(\frac{v'_{y'}}{c}\right)^2 + \left(\frac{v'_{z'}}{c}\right)^2 \right) \\
&= 1 + \beta^2 \left(\frac{v'_{x'}}{c}\right)^2 - \left(\frac{v'_{x'}}{c}\right)^2 - \beta^2 - \left(1 - \frac{v^2}{c^2}\right) \left(\left(\frac{v'_{y'}}{c}\right)^2 + \left(\frac{v'_{z'}}{c}\right)^2 \right) \\
&= (1 - \beta^2) \left(1 - \left(\frac{v'_{x'}}{c}\right)^2\right) - \left(1 - \frac{v^2}{c^2}\right) \left(\left(\frac{v'_{y'}}{c}\right)^2 + \left(\frac{v'_{z'}}{c}\right)^2 \right) \\
&= \left(1 - \frac{v^2}{c^2}\right) \left(1 - \left(\frac{v'_{x'}}{c}\right)^2 - \left(\frac{v'_{y'}}{c}\right)^2 - \left(\frac{v'_{z'}}{c}\right)^2\right) = \left(1 - \frac{v^2}{c^2}\right) \left(1 - \frac{\|\vec{v}'\|^2}{c^2}\right)
\end{aligned} \tag{12.3.85}$$

Let us put:

$$\Gamma(\vec{v})=\frac{1}{\sqrt{1-\dfrac{\|\vec{v}\|^2}{c^2}}}=\frac{1}{\sqrt{1-\left(\dfrac{x}{ct}\right)^2-\left(\dfrac{y}{ct}\right)^2-\left(\dfrac{z}{ct}\right)^2}}=\Gamma_{\vec{v}} \tag{12.3.86}$$

and:

$$\Gamma(\vec{v}')=\frac{1}{\sqrt{1-\dfrac{\|\vec{v}'\|^2}{c^2}}}=\frac{1}{\sqrt{1-\left(\dfrac{x'}{ct'}\right)^2-\left(\dfrac{y'}{ct'}\right)^2-\left(\dfrac{z'}{ct'}\right)^2}}=\Gamma_{\vec{v}'} \tag{12.3.87}$$

and:

$$\gamma=\gamma(v)=\Gamma(\vec{v})=\frac{1}{\sqrt{1-\dfrac{v^2}{c^2}}} \tag{12.3.88}$$

where the latter equality means that in order to simplify that the inertial speed and thus the study of only a single component is sufficient and that is the one collinear with the axis of movement.

With this notation and simplification it will be easy for us to determine the temporal componen! Indeed, the relation:

$$\left(1-\frac{\|\vec{v}\|^2}{c^2}\right)\left(1+\beta\frac{v'_{x'}}{c}\right)^2=\left(1-\frac{v^2}{c^2}\right)\left(1-\frac{\|\vec{v}'\|^2}{c^2}\right) \tag{12.3.89}$$

can therefore be written:

$$\frac{1}{\sqrt{1-\dfrac{\|\vec{v}\|^2}{c^2}}}\frac{1}{1+\beta\dfrac{v'_{x'}}{c}}=\frac{1}{\sqrt{1-\dfrac{v^2}{c^2}}}\frac{1}{\sqrt{1-\dfrac{\|\vec{v}'\|}{c^2}}} \tag{12.3.90}$$

$$\Gamma_{\vec{v}}\frac{1}{1+\beta\dfrac{v'_{x'}}{c}}=\Gamma_{\vec{v}'}\gamma(v)\Gamma_{\vec{v}}=\left(1+\beta\frac{v'_{x'}}{c}\right)\Gamma_{\vec{v}'}\gamma(v) \tag{12.3.91}$$

$$\Gamma_{\vec{v}}=\gamma(v)\left(\Gamma_{\vec{v}'}+\beta\frac{v'_{x'}}{c}\Gamma_{\vec{v}'}\right) \tag{12.3.92}$$

$$\Gamma_{\vec{v}}c=\gamma\left(\Gamma_{\vec{v}'}c+\beta v'_{x'}\Gamma_{\vec{v}'}\right) \tag{12.3.93}$$

The reader will have perhaps notice that we therefore have three Γ: one related to the inertial speed, the second related the norm of the vector of the particle in the reference frame O and the third related to the norm of the vector in the reference frame O'. But actually following our simplification made earlier above we know that in the repository O' the particle is at the origin in Y' and Z'.

By doing the same for each of the spatial components, we will get in the end:

$$\begin{aligned}\Gamma_{\vec{v}}c&=\gamma\left(\Gamma_{\vec{v}'}c+\beta v'_{x'}\Gamma_{\vec{v}'}\right)\\ \Gamma_{\vec{v}}v_x&=\gamma\left(\Gamma_{\vec{v}'}v'_x+\Gamma_{\vec{v}'}c\right)\\ \Gamma_{\vec{v}}v_y&=\Gamma_{\vec{v}'}v'_y\\ \Gamma_{\vec{v}}v_z&=\Gamma_{\vec{v}'}v'_z\end{aligned} \tag{12.3.94}$$

and here we have reached our goal of homogenization that allows us to write if we put:

$$\Gamma_{\vec{v}}=\gamma(\vec{v}) \qquad \Gamma_{\vec{v}'}=\gamma(\vec{v}') \tag{12.3.95}$$

the following system:

$$\boxed{\begin{pmatrix}\gamma(\vec{v})c\\ \gamma(\vec{v})v_x\\ \gamma(\vec{v})v_y\\ \gamma(\vec{v})v_z\end{pmatrix}=\gamma(\vec{v})\begin{pmatrix}c\\ v_x\\ v_y\\ v_z\end{pmatrix}=\begin{pmatrix}\gamma & \gamma\beta & 0 & 0\\ \gamma\beta & \gamma & 0 & 0\\ 0 & 0 & 1 & 0\\ 0 & 0 & 0 & 1\end{pmatrix}\begin{pmatrix}\gamma(\vec{v}')c\\ \gamma(\vec{v}')v'_x\\ \gamma(\vec{v}')v'_y\\ \gamma(\vec{v}')v'_z\end{pmatrix}} \tag{12.3.96}$$

that is written in tensor form sometimes as:

$$\boxed{u'^{\mu}=L^{\mu}_{\nu}u^{\nu} \quad \text{or} \quad u^{\nu}=L'^{\nu}_{\mu}u'^{\mu}} \tag{12.3.97}$$

The vector:

$$\boxed{u'^{\nu}=\gamma(\vec{v})(c,v_x,v_y,v_z)=\gamma(\vec{v})(c,\vec{v})} \tag{12.3.98}$$

is itself named the "four-vector velocity".

12.3.2.3 Current four-vector

We have defined naturally during our introduction of the electromagnetic tensor field (see section Electrodynamics page 4121) the four-vector current:

$$j^{\nu}=(\rho c,\vec{j}) \tag{12.3.99}$$

that we can write:

$$j^{\nu}=\rho(c,\vec{v}) \tag{12.3.100}$$

This means that charge density is related to time, while current density is related to space.

Therefore, considering ρ_0 as the charge density in the proper frame moving with velocity v relative to reference frame O' and due to length contraction in the direction of the velocity, the volume occupied by a given electric charge will be multiplied by the factor $\gamma(\vec{v})$ so that:

$$\boxed{j^{\nu}=\rho_0\gamma(\vec{v})(c,\vec{v})} \tag{12.3.101}$$

which is none other than the "four-current" where we see back the four-vector velocity previously determined.

12.3.2.4 Acceleration four-vector

Having previously obtained a four-vector velocity transformable thanks to the Lorentz matrix let us also look for the equivalent for acceleration.

The four-vector acceleration is naturally expressed as the derivative with respect to the proper time of the four-velocity u such that:

$$a^v = \frac{\mathrm{d}u^v}{\mathrm{d}t'} = \frac{\mathrm{d}t}{\mathrm{d}t'}\frac{\mathrm{d}u^v}{\mathrm{d}t} \tag{12.3.102}$$

Let us just recall that the proper time of a particle is the time measured in the coordinate system of the particle, that is to say, in the reference frame where it is motionless. The proper time in the literature is often denoted τ.

Remark

We must be careful and check that the corollary of the assumption of the equivalence principle is true otherwise all General Relativity would collapse! In this early 121st century - holocene calendar - experiments (like [482]) are still trying to find a default to this principle!

The reader must first admit that (we will prove this further below) that:

$$\frac{\mathrm{d}t}{\mathrm{d}t'} = \frac{1}{\sqrt{1-\dfrac{v^2}{c^2}}} = \gamma \tag{12.3.103}$$

Therefore, we have:

$$a^v = \frac{\mathrm{d}t}{\mathrm{d}t'}\frac{\mathrm{d}u^v}{\mathrm{d}t} = \gamma\frac{\mathrm{d}}{\mathrm{d}t}(c\gamma,\gamma\vec{v}) \tag{12.3.104}$$

If we introduce the ordinary acceleration $\vec{a} = \mathrm{d}\vec{v}/\mathrm{d}t$ we see that:

$$\frac{\mathrm{d}\gamma}{\mathrm{d}t} = \frac{1}{2c^2}\gamma^3\frac{\mathrm{d}}{\mathrm{d}t}(\|\vec{v}\|^2) = \frac{1}{2c^2}\gamma^3\frac{\mathrm{d}}{\mathrm{d}t}(\vec{v}\circ\vec{v}) = \frac{\gamma^2}{2c^2}(\vec{a}\circ\vec{v}+\vec{v}\circ\vec{a}) = \frac{\gamma^3}{c^2}\vec{v}\circ\vec{a} \tag{12.3.105}$$

then:

$$a^v = \gamma\frac{\mathrm{d}}{\mathrm{d}t}(c\gamma,\gamma\vec{v}) = \gamma\left(\frac{\gamma^3}{c}\vec{v}\circ\vec{a},\gamma\vec{a}+\frac{\gamma^3}{c^2}(\vec{v}\circ\vec{a})\vec{v}\right) \tag{12.3.106}$$

Using the dual vector product identity (see section Vector Calculus page 1835):

$$(\vec{v}\circ\vec{a})\vec{v} = \vec{v}\times(\vec{v}\times\vec{a})+(\vec{v}\circ\vec{v})\vec{a} \tag{12.3.107}$$

we then find that the four-vector acceleration can be written:

$$\begin{aligned}a^v &= \gamma^3\left(\vec{b}\circ\vec{a},\frac{\vec{a}}{\gamma^2}+\frac{1}{c^2}(\vec{v}\circ\vec{a})\vec{v}\right) = \gamma^4\left(\vec{\beta}\circ\vec{a},\frac{\vec{a}}{\gamma^2}+\frac{1}{c^2}(\vec{v}\times(\vec{v}\times\vec{a})+(\vec{v}\circ\vec{v})\vec{a})\right)\\ &= \gamma^4\left(\vec{\beta}\circ\vec{a},\frac{\vec{a}}{\gamma^2}+(\vec{\beta}\times(\vec{\beta}\times\vec{a})+(\vec{\beta}\circ\vec{\beta})\vec{a})\right) = \gamma^4\left(\vec{\beta}\circ\vec{a},\left(\frac{1}{\gamma^2}+\vec{\beta}\circ\vec{\beta}\right)\vec{a}+\vec{\beta}\times(\vec{\beta}\times\vec{a})\right)\\ &= \gamma^4\left(\vec{\beta}\circ\vec{a},((1-\vec{\beta}\circ\vec{\beta})+\vec{\beta}\circ\vec{\beta})\vec{a}+\vec{\beta}\times(\vec{\beta}\times\vec{a})\right) = \gamma^4(\vec{\beta}\circ\vec{a},\vec{a}+\vec{\beta}\times(\vec{\beta}\times\vec{a}))\end{aligned} \tag{12.3.108}$$

The vector:

$$\boxed{a^v = \gamma^4 \left(\vec{\beta} \circ \vec{a}, \vec{a} + \vec{\beta} \times (\vec{\beta} \times \vec{a})\right)} \tag{12.3.109}$$

is named "four-vector acceleration" and therefore also transforms using the Lorentz matrix.

We see that if this $v \ll c$ and $\vec{a} = \vec{a}_0$ the last relation simplifies to:

$$a^v = \gamma^4 \left(\vec{\beta} \circ \vec{a}, \vec{a} + \vec{\beta} \times (\vec{\beta} \times \vec{a})\right) = 1(\vec{0} \circ \vec{a}, \vec{a} + \vec{0} \times (\vec{0} \times \vec{a})) = (0, \vec{a}) \tag{12.3.110}$$

We thus fall back on the classic acceleration.

Using the Minkowski metric (see definition further below), denoted η_{uv}, let us calculate the norm of the four-vector acceleration:

$$\begin{aligned} a^v a_v &= a^v(\eta_{uv} a^v) = a^0 a_0 - a_i a^i = \gamma^8 \left[(\vec{\beta} \circ \vec{a})^2 - \left(\vec{a} + \vec{\beta} \times (\vec{\beta} \times \vec{a})\right)^2\right] \\ &= \gamma^8 \left[(\vec{\beta} \circ \vec{a})^2 - \left(\vec{a} + \underbrace{(\vec{\beta} \circ \vec{a})\vec{\beta} - (\vec{\beta} \circ \vec{\beta})\vec{a}}_{=\vec{c}}\right)^2\right] = \gamma^8 \left[(\vec{\beta} \circ \vec{a})^2 + (\vec{a} + \vec{c})^2\right] \\ &= \gamma^8 \left[(\vec{\beta} \circ \vec{a})^2 - (\vec{a}^2 + 2\vec{a}\vec{c} + \vec{c}^2)\right] \end{aligned} \tag{12.3.111}$$

Remark

It must be well understood that when we write $(\vec{a} + \vec{\beta} \times (\vec{\beta} \times \vec{a}))^2$ it is implicit in this case that we do the sum of the squares of the components of the calculations in the brackets!

And as:

$$\vec{c}^2 = (\vec{\beta} \circ \vec{a})^2 \vec{\beta}^2 - 2(\vec{\beta} \circ \vec{\beta})(\vec{\beta} \circ \vec{a})\vec{\beta}\vec{a} + (\vec{\beta} \circ \vec{\beta})^2 \vec{a}^2 \tag{12.3.112}$$

and:

$$\vec{a}\vec{c} = (\vec{\beta} \circ \vec{a})\vec{\beta}\vec{a} - (\vec{\beta} \circ \vec{\beta})\vec{a}^2 \tag{12.3.113}$$

we put this together to get:

$$a^v a_v = \gamma^8 \left[(\vec{\beta} \circ \vec{a})^2 - \left(\begin{array}{c} \vec{a}^2 + 2(\vec{\beta} \circ \vec{a})\vec{\beta}\vec{a} - 2(\vec{\beta} \circ \vec{\beta})\vec{a}^2 + \\ (\vec{\beta} \circ \vec{a})^2 \vec{\beta}^2 - 2(\vec{\beta} \circ \vec{\beta})(\vec{\beta} \circ \vec{a})\vec{\beta}\vec{a} + (\vec{\beta} \circ \vec{\beta})^2 \vec{a}^2 \end{array}\right)\right] \tag{12.3.114}$$

Now we develop the sum $a_i a^i$ of the big parenthesis that becomes therefore:

$$\begin{aligned} a^v a_v &= \gamma^8 \left[(\beta_i a^i)^2 - \left(\begin{array}{c} a_i a^i + 2(\beta_i a^i)(\beta_i a^i) - 2(\beta_i \beta^i) a_i a^i + \\ (\beta_i a^i)^2 (\beta_i \beta^i) - 2(\beta_i \beta^i)(\beta_i a^i)(\beta_i a^i) + (\beta_i \beta^i)^2 a_i a^i \end{array}\right)\right] \\ &= \gamma^8 \left[(\beta_i a^i)^2 - \left(\begin{array}{c} a_i a^i + 2(\beta_i a^i)^2 - 2(\beta_i \beta^i) a_i a^i + \\ (\beta_i a^i)^2 (\beta_i \beta^i) - 2(\beta_i \beta^i)(\beta_i a^i)^2 + (\beta_i \beta^i)^2 a_i a^i \end{array}\right)\right] \end{aligned} \tag{12.3.115}$$

We simplify:

$$\begin{aligned} a^v a_v &= \gamma^8 \left[(\beta_i a^i)^2 (1 - 2 - \beta_i \beta^i + 2\beta_i \beta^i) + a_i a^i \left(-1 + 2\beta_i \beta^i - (\beta_i \beta^i)^2\right)\right] \\ &= \gamma^8 \left[(\vec{\beta} \circ \vec{a})^2 (1 - 2 - \vec{\beta}^2 + 2\vec{\beta}^2) + \vec{a}^2 (-1 + 2\vec{\beta} - \vec{\beta}^4)\right] \end{aligned} \tag{12.3.116}$$

Hence:

$$\begin{aligned}a^v a_v &= \gamma^8\left[(\vec{\beta}\circ\vec{a})^2(1-2-\vec{\beta}^2+2\vec{\beta}^2)+\vec{a}^2(-1+1\vec{\beta}^2-\vec{\beta}^4)\right]\\&=\gamma^8\left[(\vec{\beta}\circ\vec{a})^2(-1+\vec{\beta}^2)+\vec{a}^2(-1+2\vec{\beta}^2-\vec{\beta}^4)\right]\\&=-\gamma^8(1-\vec{\beta}^2)\left[(\vec{\beta}\circ\vec{a})^2+\vec{a}^2(1-\vec{\beta}^2)\right]=-\gamma^8\gamma^{-2}\left[(\vec{\beta}\circ\vec{a})^2+\vec{a}(1-\vec{\beta}^2)\right]\\&=-\gamma^6\left[(\vec{a}\circ\vec{\beta})^2+\vec{a}^2(1-\vec{\beta}^2)\right]=-\gamma^6\left\{\vec{a}^2-\left[\vec{a}^2\vec{\beta}^2-(\vec{a}\circ\vec{\beta})^2\right]\right\}\end{aligned}\tag{12.3.117}$$

But we have the relation:

$$\|\vec{a}\times\vec{\beta}\|^2=\vec{a}^2\vec{\beta}^2-(\vec{a}\circ\vec{\beta})^2=(a_ia^i)(\beta_i\beta^i)-(a_i\beta^i)^2\tag{12.3.118}$$

and the property of the cross product:

$$\vec{a}\times\vec{\beta}=-\vec{\beta}\times\vec{a}\tag{12.3.119}$$

Which finally gives us:

$$a^v a_v=-\gamma^6\left[\vec{a}^2-(\vec{a}\times\vec{\beta})^2\right]=-\gamma^6\left[\vec{a}\circ\vec{a}-(\vec{a}\times\vec{\beta})\circ(\vec{a}\times\vec{\beta})\right]=-\gamma^6\left[\vec{a}^2-(\vec{\beta}\times\vec{a})^2\right]\tag{12.3.120}$$

The relation:

$$\boxed{a^v a_v=-\gamma^6\left[\vec{a}^2-(\vec{\beta}\times\vec{a})^2\right]}\tag{12.3.121}$$

will be extremely useful to us when we will study the Abraham-Becker radiation damping force in the section of Electrodynamics (see page 4191).

Now imagine an object with a uniformly accelerated relative motion $\vec{a}_0^2$ (constant acceleration) in our own repository. If we assume our repository as fixed, we have $\vec{v}=\vec{0}\Leftrightarrow\vec{\beta}=\vec{0}$. Therefore:

$$a^v a_v=-\gamma^6\vec{a}^2=-\vec{a}_0^2\tag{12.3.122}$$

Verbatim after rearranging the terms and taking the square root if the accelerated motion is made only along a single component:

$$\gamma^3\frac{\mathrm{d}u}{\mathrm{d}t}=a_0\tag{12.3.123}$$

But, we also have:

$$\frac{\mathrm{d}}{\mathrm{d}t}(\gamma u)=\gamma\frac{\mathrm{d}u}{\mathrm{d}t}+u\frac{\mathrm{d}\gamma}{\mathrm{d}t}=\gamma^3\frac{\mathrm{d}u}{\mathrm{d}t}\left(\gamma^{-2}+\frac{u^2}{c^2}\right)=\gamma^3\frac{\mathrm{d}u}{\mathrm{d}t}\left(1-\frac{u^2}{c^2}+\frac{u^2}{c^2}\right)=\gamma^3\frac{\mathrm{d}u}{\mathrm{d}t}\tag{12.3.124}$$

So finally, we can write:

$$\gamma^3\frac{\mathrm{d}u}{\mathrm{d}t}=\frac{\mathrm{d}}{\mathrm{d}t}(\gamma u)=\frac{\mathrm{d}}{\mathrm{d}t}\frac{u}{\sqrt{1-\dfrac{u^2}{c^2}}}=a_0\tag{12.3.125}$$

Which after integration gives:

$$\boxed{u=\frac{\mathrm{d}x}{\mathrm{d}t}=\frac{a_0}{\sqrt{1+\frac{a_0^2t^2}{c^2}}}} \tag{12.3.126}$$

We see that the speed u never reaches c while the force (acceleration implicitly) is always the same!

So we have:

$$x=\frac{c^2}{a_0}\int\limits_0^{a_0t/c}\frac{x}{\sqrt{1+x^2}}\mathrm{d}x=\frac{c^2}{a_0}\sqrt{1+\frac{a_0^2t^2}{c^2}}-\frac{c^2}{a_0} \tag{12.3.127}$$

which gives us:

$$\left(x+\frac{c^2}{a_0}\right)^2-c^2t^2=\frac{c^4}{a_0^2} \tag{12.3.128}$$

After rearranging, we write this:

$$\boxed{x=\frac{c^2}{a_0}\left(\sqrt{1+\frac{a_0^2t^2}{c^2}}-1\right)} \tag{12.3.129}$$

We are far from the relation of uniformly accelerated motion we have proved in the section of Classical Mechanics (see page 3224) and that is for recall:

$$x=\frac{1}{2}a_0t^2 \tag{12.3.130}$$

However, for t close to zero, we fall back on the same Classical Mechanics relation by taking the Taylor expansion to the second order of the square root (see section Sequences and Series page 1703):

$$x=\frac{c^2}{a_0}\left(\sqrt{1+\frac{a_0^2t^2}{c^2}}\right)\cong\frac{c^2}{a_0}\left(1+\frac{a_0^2t^2}{2c^2}-1\right)=\frac{1}{2}a_0t^2 \tag{12.3.131}$$

However, this does not give us the relations of transformation of acceleration components in a simple form. Let's see how to get them.

First let us recall that we have obtained for speed:

$$v_x=\frac{v'_{x'}+v}{1+\frac{v}{c}v'_{x'}},\ v_y=\frac{v'_{y'}}{\gamma\left(1+\frac{v}{c}v'_{x'}\right)},\ v_z=\frac{v'_{z'}}{\gamma\left(1+\frac{v}{c}v'_{x'}\right)} \tag{12.3.132}$$

Then it comes by differentiating:

$$\begin{aligned}\mathrm{d}v_x &= \mathrm{d}\left((v'_{x'}+v)\frac{1}{1+\dfrac{v}{c^2}v'_{x'}}\right) = \frac{\mathrm{d}v'_{x'}}{1+\dfrac{v}{c^2}v'_{x'}} + \frac{\underbrace{\mathrm{d}v}_{=0}}{1+\dfrac{v}{c^2}v'_{x'}} + (v'_{x'}+v)\mathrm{d}\left(1+\frac{v}{c^2}v'_{x'}\right)^{-1}\\ &= \frac{\mathrm{d}v'_{x'}}{1+\dfrac{v}{c^2}v'_{x'}} - \frac{v'_{x'}+v}{\left(1+\dfrac{v}{c^2}v'_{x'}\right)^2}\frac{v}{c^2}\mathrm{d}v'_{x'} = \frac{\mathrm{d}v'_{x'}\left(1+\dfrac{v}{c^2}v'_{x'}\right)-(v'_{x'}+v)\dfrac{v}{c^2}\mathrm{d}v'_{x'}}{\left(1+\dfrac{v}{c^2}v'_{x'}\right)^2}\\ &= \frac{\mathrm{d}v'_{x'}+\dfrac{v}{c^2}v'_{x'}\mathrm{d}v'_{x'}-v'_{x'}\dfrac{v}{c^2}\mathrm{d}v'_{x'}-v\dfrac{v}{c^2}\mathrm{d}v'_{x'}}{\left(1+\dfrac{v}{c^2}v'_{x'}\right)^2} = \frac{\mathrm{d}v'_{x'}-v\dfrac{v}{c^2}\mathrm{d}v'_{x'}}{\left(1+\dfrac{v}{c^2}v'_{x'}\right)^2}\end{aligned} \tag{12.3.133}$$

therefore:

$$\frac{\mathrm{d}v_x}{\mathrm{d}t} = \frac{1}{\gamma^2\left(1+\dfrac{v}{c^2}v'_{x'}\right)^2}\frac{\mathrm{d}v'_{x'}}{\mathrm{d}t} = \frac{1}{\gamma^2\left(1+\dfrac{v}{c^2}v'_{x'}\right)^2}\frac{\mathrm{d}t'}{\mathrm{d}t}\frac{\mathrm{d}v'_{x'}}{\mathrm{d}t'} = \frac{1}{\gamma^2\left(1+\dfrac{v}{c^2}v'_{x'}\right)^2}\frac{\mathrm{d}t'}{\mathrm{d}t}a'_{x'} \tag{12.3.134}$$

Let us recall now that we have proved that:

$$ct = \gamma(t'c+\beta x') \tag{12.3.135}$$

differentiating it comes:

$$c\mathrm{d}t = \gamma(\mathrm{d}t'c+\beta\mathrm{d}x') \tag{12.3.136}$$

We can write:

$$c\frac{\mathrm{d}t}{\mathrm{d}t'} = \frac{\gamma}{\mathrm{d}t'}(\mathrm{d}t'c+\beta\mathrm{d}x') \tag{12.3.137}$$

After simplifying and rearranging we get obviously:

$$\frac{\mathrm{d}t}{\mathrm{d}t'} = \gamma\left(1+\frac{\beta v'_x}{c}\right) \tag{12.3.138}$$

Hence:

$$\frac{\mathrm{d}t'}{\mathrm{d}t} = \frac{1}{\gamma\left(1+\dfrac{\beta v'_x}{c}\right)} = \frac{1}{\gamma\left(1+\dfrac{vv'_x}{c^2}\right)} \tag{12.3.139}$$

hence finally:

$$a_x = \frac{\mathrm{d}v_x}{\mathrm{d}t} = \frac{1}{\gamma^2\left(1+\dfrac{v}{c^2}v'_{x'}\right)^2}\frac{\mathrm{d}t'}{\mathrm{d}t}a'_{x'} = \frac{1}{\gamma^3\left(1+\dfrac{v}{c^2}v'_{x'}\right)^3}a'_{x'} \tag{12.3.140}$$

and for the components y, z:

$$v_{y,z} = \frac{v'_{y',z'}}{\gamma\left(1+\dfrac{v}{c^2}v'_{x'}\right)} \Rightarrow \mathrm{d}v_{y,z} = \frac{\mathrm{d}v'_{y',z'}}{\gamma\left(1+\dfrac{v}{c^2}v'_{x'}\right)} - \frac{v'_{y',z'}}{\gamma\left(1+\dfrac{v}{c^2}v'_{x'}\right)^2}\frac{v}{c^2}\mathrm{d}v'_{x'} \tag{12.3.141}$$

and therefore:

$$\begin{aligned}\frac{\mathrm{d}v_{y,z}}{\mathrm{d}t}&=\left(\frac{1}{\gamma\left(1+\dfrac{v}{c^2}{v'}_{x'}\right)}\frac{\mathrm{d}{v'}_{y',z'}}{\mathrm{d}t}-\frac{{v'}_{y',z'}}{\gamma\left(1+\dfrac{v}{c'^2}{v'}_{x'}\right)^2}\right)\frac{\mathrm{d}t'}{\mathrm{d}t'}\\&=\frac{{a'}_{y',z'}}{\gamma^2\left(1+\dfrac{v}{c^2}{v'}_{x'}\right)^2}-\frac{v{v'}_{y',z'}}{c^2}\frac{{a'}_{x'}}{\gamma^2\left(1+\dfrac{v}{c'^2}{v'}_{x'}\right)^3}\end{aligned} \tag{12.3.142}$$

So finally:

$$\boxed{\begin{aligned}a_x&=\frac{1}{\gamma^3\left(1+\dfrac{v}{c^2}{v'}_{x'}\right)^3}{a'}_{x'}\\a_y&=\frac{{a'}_{y'}}{\gamma^2\left(1+\dfrac{v}{c^2}{v'}_{x'}\right)^2}-\frac{v{v'}_{y'}}{c^2}\frac{{a'}_{x'}}{\gamma^2\left(1+\dfrac{v}{c^2}{v'}_{x'}\right)^3}\\a_z&=\frac{{a'}_{z'}}{\gamma^2\left(1+\dfrac{v}{c^2}{v'}_{x'}\right)^2}-\frac{v{v'}_{z'}}{c^2}\frac{{a'}_{x'}}{\gamma^2\left(1+\dfrac{v}{c^2}{v'}_{x'}\right)^3}\end{aligned}} \tag{12.3.143}$$

Remember that these relations apply when the movements of the reference frames are in uniform translation!

Caution! It is a common misconception that we cannot speak about acceleration in Special Relativity. But that's a wrong belief from scientifically illiterate people and undergraduate students as we have just seen it! What we can't do with acceleration in Special Relativity is to use a simple Lorentz transformation for the acceleration or to find time and space Lorentz boosts that includes acceleration. That's all!!!!

12.3.2.5 Relativistic sum of velocities

As the speed of light is a speed supposed unsurpassable, we now come to ask ourselves what will be finally the speed of an object launched at a speed close to that of light (for example...) from a reference frame moving also close to that of the speed of light (why not...).

We must then find a relation that gives the real speed V from the launch speed v_2 and speed of the repository v_1.

We know that for the object launched:

$$x'=v_2t' \tag{12.3.144}$$

As the one who is concerned does not know the real speed V, it should use the Lorentz transformations. Thus, given the expression of t' that we saw earlier it comes:

$$x'=v_2\frac{t-\dfrac{v_1x}{c^2}}{\sqrt{1-\left(\dfrac{v_1}{c}\right)^2}} \tag{12.3.145}$$

and given the prior-previous expression of x' we also have:

$$\frac{x-v_1t}{\sqrt{1-\left(\dfrac{v_1}{c}\right)^2}}=v_2\frac{t-\dfrac{v_1x}{c^2}}{\sqrt{1-\left(\dfrac{v_1}{c}\right)^2}} \tag{12.3.146}$$

therefore after rearranging and simplifying a bit:

$$x-v_1t=v_2\left(t-\frac{v_1x}{c}\right)=v_2t-\frac{v_2v_1x}{c^2} \tag{12.3.147}$$

Hence:

$$x\left(1+\frac{v_2v_1}{c^2}\right)=t(v_2+v_1) \tag{12.3.148}$$

We know that $v=x/t$ so we can finally write the "law of compositions relativistic speeds" or simply "velocity-addition formula" or "Einstein's velocity addition" relation:

$$\boxed{V=\frac{x}{t}=\frac{v_1+v_2}{1+\dfrac{v_2v_2}{c^2}}} \tag{12.3.149}$$

which is therefore the speed of a moving body in the moving reference frame relatively to that seen in the rest frame (but that in fact could also move at any speed less then c).

And conversely seen from the other moving frame of reference, we have by the same developments (with reverse signs and speed of course):

$$\boxed{V'=\frac{x'}{t'}=\frac{v_2-v_1}{1-\dfrac{v_1v_2}{c^2}}} \tag{12.3.150}$$

which is the speed of a moving body in the rest frame relatively to that considered as being in motion (or in other words seen by the moving frame of reference).

Notice that for small speeds, we fall back obviously on the Galilean addition relation:

$$V=\frac{v_1+v_2}{1+\dfrac{v_2v_2}{c^2}}=v_1+v_2 \tag{12.3.151}$$

If we take the speed of light as one of the velocities, we get:

$$V=\frac{v_1+v_2}{1+\dfrac{v_2v_2}{c^2}}=\frac{v_1+c}{1+\dfrac{v_2c}{c^2}}=\frac{v_1+c}{1+\dfrac{v_2}{c}}=c \tag{12.3.152}$$

Hence the speed of light cannot be surpassed!

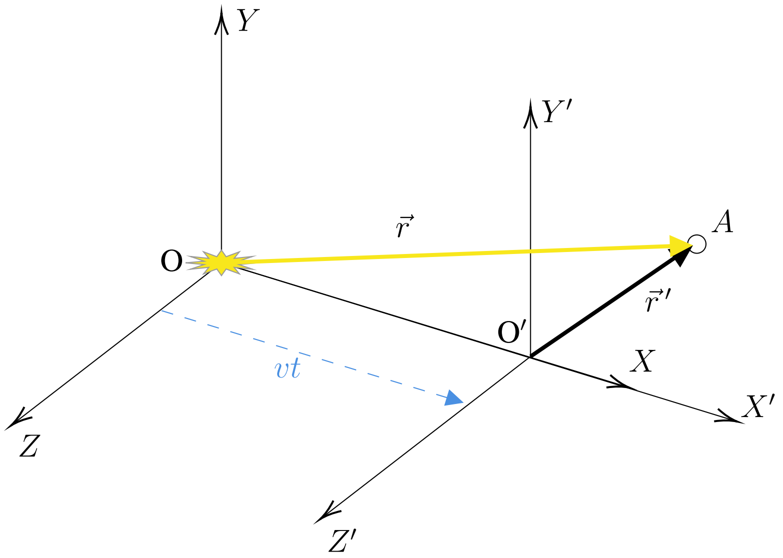
On the other hand, if we take two velocities smaller than that of light, we have, with $v_1=c-\lambda$, $v_2=c-\mu$ and $\lambda,\mu>0$:

$$\begin{aligned}V&=\frac{2c-\lambda-\mu}{1+\dfrac{(c-\lambda)(c-\mu)}{c^2}}=c\frac{2c-\lambda-\mu}{2c-\lambda-\mu+\dfrac{\lambda\mu}{c}}\\&=\frac{c}{1+\dfrac{\lambda\mu}{c(2c-\lambda-\mu)}}\leq c\end{aligned} \tag{12.3.153}$$

Then it is not possible to reach the speed of light by adding speed less than that of light!

12.3.2.6 Relativistic lengths variation (length contraction)

Let us consider now that the length of an object is given by the distance between its two ends A and B. Let us consider this object $\overline{AB}$ motionless in the repository O$'$ in uniform translation and oriented along the axis O$'X'$:



Its length is then the distance between its both ends:

$$L' = x'_B - x'_A \tag{12.3.154}$$

For the observer O, the object is moving. The positions A and B should therefore be measured simultaneously:

$$L' = x'_B - x'_A \tag{12.3.155}$$

So it comes using the relation proved earlier in this section:

$$x' = \gamma(x - vt) = \frac{x - vt}{\sqrt{1 - \left(\dfrac{v}{c}\right)^2}} \tag{12.3.156}$$

the following difference:

$$L' = x'_B - x'_A = \frac{x_B - vt}{\sqrt{1 - \left(\dfrac{v}{c}\right)^2}} - \frac{x_A - vt}{\sqrt{1 - \left(\dfrac{v}{c}\right)^2}} = \frac{X_B - X_A}{\sqrt{1 - \left(\dfrac{v}{c}\right)^2}} = \frac{L}{\sqrt{1 - \left(\dfrac{v}{c}\right)^2}} \tag{12.3.157}$$

hence the remarkable result:

$$\boxed{L = L'\sqrt{1 - \left(\frac{v}{c}\right)^2}} \tag{12.3.158}$$

we also find the relation frequently in the literature as follows:

$$\boxed{\Delta L = \Delta L'\sqrt{1 - \frac{v^2}{c^2}}} \tag{12.3.159}$$

Thus, the length of an observed rule in a moving frame relatively to the proper frame of the rule is less than its own length (which can assimilate in generality to a "proper length"). In other words, the length of a moving object measured by the fixed reference frame will be measured shorter than its real proper size. This phenomenon is named "length contraction".

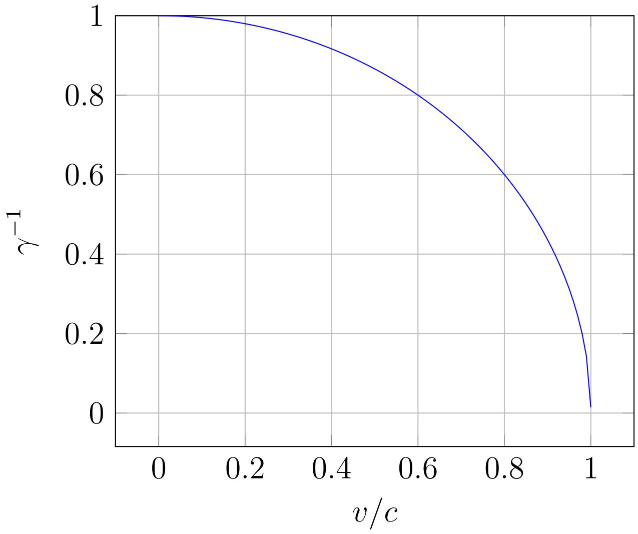


Figure 12.197: Lorentz factor length contraction function trend

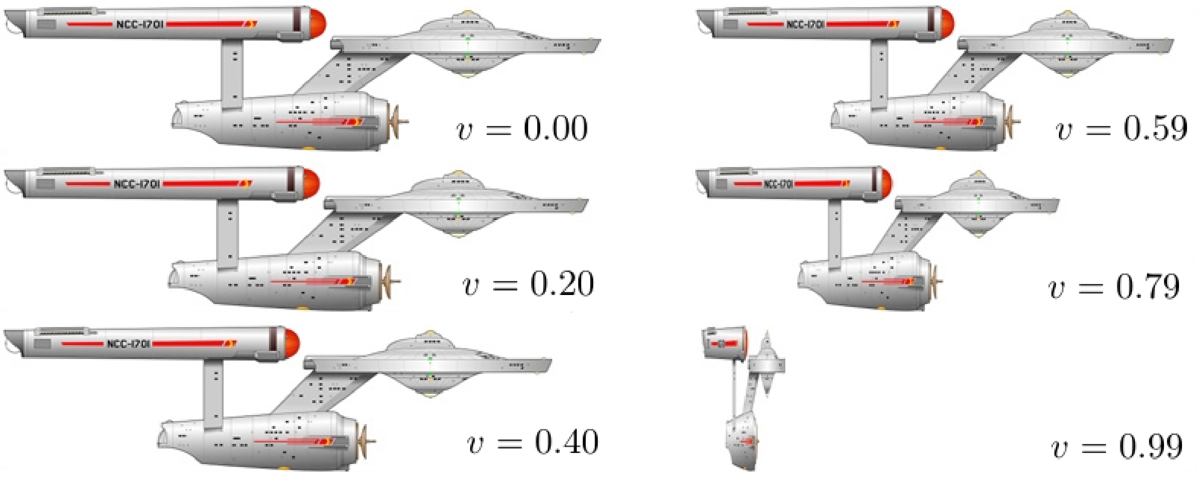

Figure 12.198: Length contraction principle for rectilinear motion (source:?)

Due to superficial application of the contraction formula some paradoxes can occur. Examples are the "ladder paradox" and "Bell's spaceship paradox". However, those paradoxes can simply be solved by a correct application of relativity of simultaneity. Another famous paradox is the "Ehrenfest paradox" (high relativistic speed "rigid" rotating disc[39]), which proves that the concept of rigid bodies is not compatible with relativity, reducing the applicability of Born rigidity, and showing that for a co-rotating observer the geometry is in fact non-euclidean and we need then to use General Relativity.

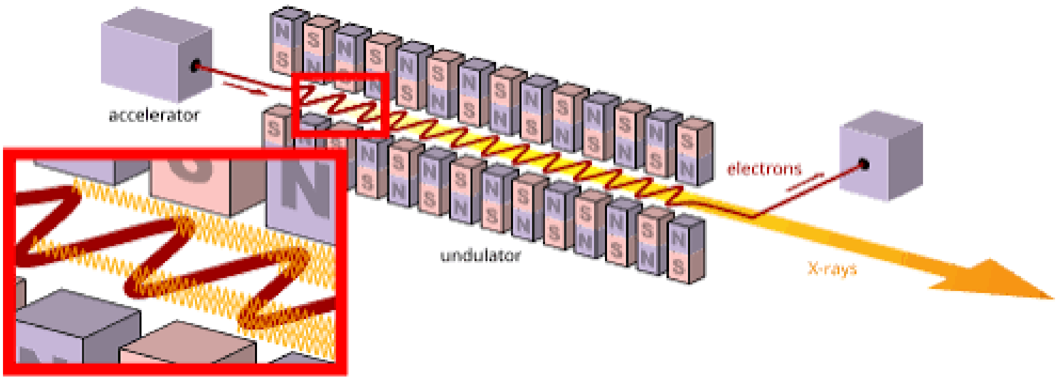
---

[39] Circumference of a rotating disk should contract but not the radius, as radius is perpendicular to the direction of motion.

Caution! As we already have proved it earlier, length contraction, when expressed in the formalism of matrix algebra, is in fact a rotation in space-time (a hyperbolic rotation!!!)! So physically an object isn't smaller when moving, but is just seen with a different angle (i.e. in a different perspective angle) than the perpendicular one by default (at $v = 0$) in space-time, and hence it looks smaller (however length contraction isn't also a visual effect as may make think the last sentence!).

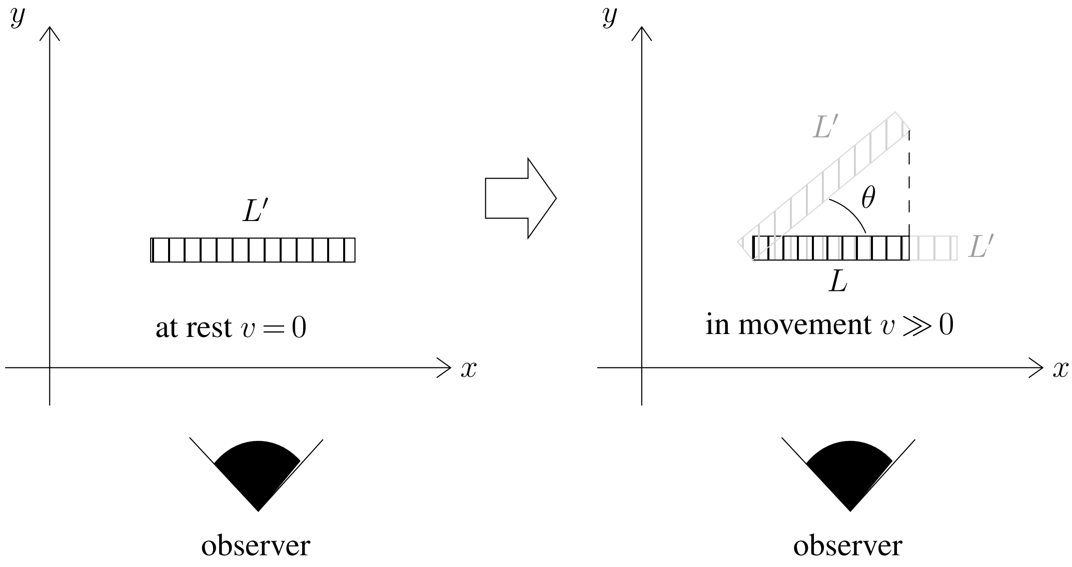
Notice that at the day we write these line (end of year 12026 according to Holocene calendar), as far as we know, it seems that there is still no direct experimental evidence of relativistic lorentz length contraction (it's indeed quite hard to measure the length of an object while it is moving at very high velocity...).

The SLAC (Stanford Linear Accelerator) X-ray free-electron LASER is in our opinion the most impressive indirect evidence of the Lorenz length contraction as it works because electrons are pushed to energies so high that relativistic effects dominate their behaviour. When these electrons travel through the undulator - a long structure with alternating magnetic fields - the spacing of those magnetic fields is fixed in the laboratory, but not in the electrons' own frame of reference. Since the electrons move extremely close to the speed of light, they experience Lorentz length contraction, which makes the undulator's magnetic period appear shorter by a Lorenz factor γ of $27,500$ (corresponding to 99.9999999338843% the speed of light [459]). In that contracted frame, the electrons feel much faster magnetic oscillations than the physical device would suggest. Because electrons radiate at the frequency of their oscillatory motion, this contracted period forces them to emit radiation at a much higher frequency that are used afterwards to image electrons clouds in molecules developed mainly for medical research. SLAC is therefore a practical demonstration of Special Relativity in action. This Linac Coherent Light Source (LCLS) works as it does because the electrons' relativistic motion makes a centimeter-scale magnetic structure behave, from their perspective, like a structure with a period thousands of times smaller. This relativistic shrinking is what makes X-ray LASER production feasible in a real-world accelerator.



12.3.2.7 Relativistic apparent angle rotation (Lampa–Terrell–Penrose effect)

The reader may have noticed something. The result of length contraction we have derived above for an imaginary one dimensional line is equivalent as if the line was rotated as illustrated below by an angle θ:



We have immediately:

$$\cos(\theta)=\frac{L}{L'}=\frac{L'\sqrt{1-\left(\dfrac{v}{c}\right)^2}}{L'}=\sqrt{1-\left(\frac{v}{c}\right)^2} \tag{12.3.160}$$

Hence:

$$\theta=\arccos\left(\sqrt{1-\left(\frac{v}{c}\right)^2}\right) \tag{12.3.161}$$

We can find the above relation written differently using the trigonometric identity:

$$\cos^2(\alpha)+\sin^2(\alpha)=1 \tag{12.3.162}$$

Therefore:

$$\cos^2(\arcsin(x))+\sin^2(\arcsin(x))=1 \tag{12.3.163}$$

Hence:

$$\cos^2(\arcsin(x))+x^2=1 \tag{12.3.164}$$

Finally:

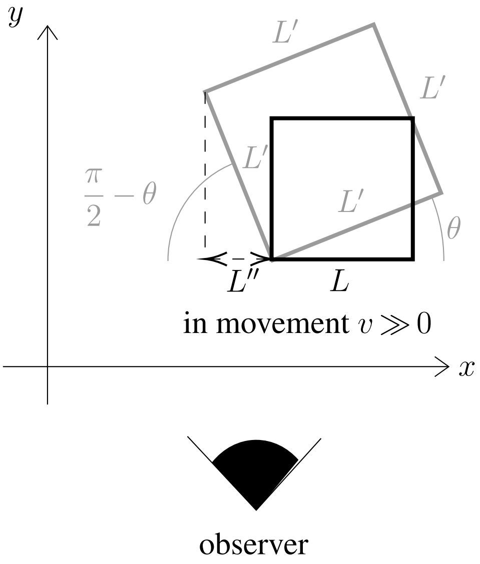
$$\arcsin(x)=\arccos\left(\sqrt{1-x^2}\right) \tag{12.3.165}$$

So the above relation can be written as the "relativistic apparent angle rotation":

$$\boxed{\theta = \arccos\left(\sqrt{1-\left(\frac{v}{c}\right)^2}\right) = \arcsin\left(\frac{v}{c}\right)} \tag{12.3.166}$$

If we assume the equivalence that a contraction is equivalent to a rotation! That means we should be able to see the left side of the rode (or stick) - that is not visible when the speed is zero - and therefore the total length observed is not only that of given by L (contracted length) but also we have to add to it a fraction of the thickness of the rode (or stick)! That also means that the illustration above with the Spaceship is inaccurate! We should be able to see the side of the ship as it approach the speed of light!

In the case of a cube of side L' we can illustrate the situation as following:



We have from the figure above:

$$\cos\left(\frac{\pi}{2}-\theta\right) = \frac{L''}{L'} \tag{12.3.167}$$

Hence using trigonometric identities:

$$\cos(\theta) = \frac{L''}{L'} \tag{12.3.168}$$

Therefore rearranging and using previous result:

$$L'' = L'\sin(\theta) = L'\sin\left(\arcsin\left(\frac{v}{c}\right)\right) = L'\frac{v}{c} \tag{12.3.169}$$

Hence the total length seen by the observer:

$$L'\frac{v}{c} + L'\sqrt{1-\left(\frac{v}{c}\right)^2} \tag{12.3.170}$$

The "Terrell rotation" or "Terrell effect" is the visual distortion that a passing object would appear to undergo, according to the special theory of relativity if it were travelling at a significant fraction of the speed of light. This behaviour was described independently by both Roger

Penrose and James Terrell. Penrose's article was submitted 29 July 11958 (holocene calendar) and published in January 11959 (holocene calendar). Terrell's article was submitted 22 June 11959 (holocene calendar) and published 15 November 11959 (holocene calendar). The general phenomenon was noted already in 11924 (holocene calendar) by Austrian physicist Anton Lampa.

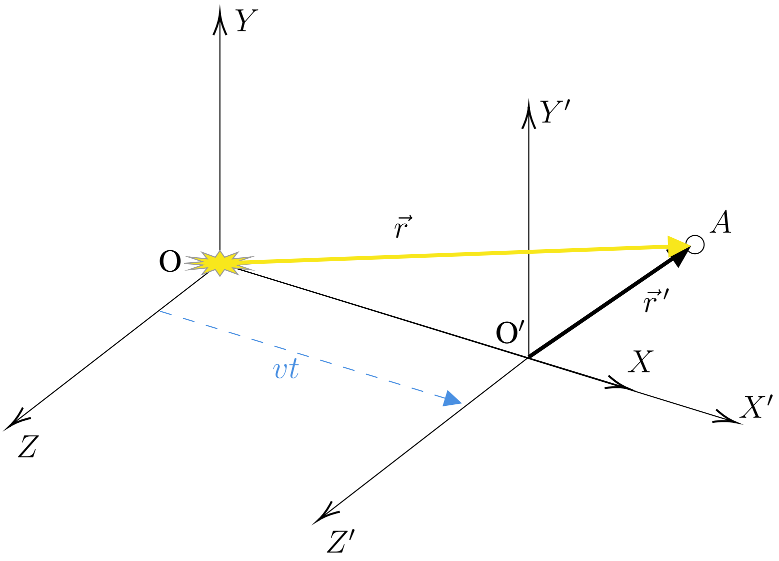
Due to a dispute about priority and correct attribution, the effect is also sometimes referred to as the "Penrose–Terrell effect", the "Terrell–Penrose effect" or the "Lampa–Terrell–Penrose effect", but not the "Lampa effect".

Notice that at the day we write these line (end of year 12026 according to Holocene calendar), as far as we know, it seems that there is still no direct experimental evidence of the Lampa-Terrell-Penrose effect (it's indeed quite hard to measure the detailed shape of an object while it is moving at very high velocity...).

12.3.2.8 Relativistic time variation (time dilatation)

An event is a phenomenon that occurs in a given place at a given time. The origin of time is difficult to determine, we often prefer to define the concept of "time interval" as the time elapsed between two events as it is often customary (see section Principia page 3083).

Let us now consider two consecutive events A and B that occur at the same location x' (!) in the repository in uniform translation:



For the observer in O′, the time interval is simply:

$$\Delta t' = t'_B - t'_A \qquad (12.3.171)$$

To measure this time interval, the observer O in the fixed reference repository should also require that x' is common to both events. Then using the relation proved earlier above:

$$t'=\gamma\left(t-\frac{v}{c^2}x\right)=\frac{t-\dfrac{v}{c^2}x}{\sqrt{1-\left(\dfrac{v}{c}\right)^2}} \quad (12.3.172)$$

we get:

$$\Delta t=t_B-t_A=\frac{t'_B+\dfrac{vx'}{c^2}}{\sqrt{1-\left(\dfrac{v}{c}\right)^2}}-\frac{t'_A+\dfrac{vx'}{c^2}}{\sqrt{1-\left(\dfrac{v}{c}\right)^2}}=\frac{t'_B-t'_A}{\sqrt{1-\left(\dfrac{v}{c}\right)^2}}=\frac{\Delta t'}{\sqrt{1-\left(\dfrac{v}{c}\right)^2}} \quad (12.3.173)$$

hence the remarkable result:

$$\boxed{\Delta t=\frac{\Delta t'}{\sqrt{1-\left(\dfrac{v}{c}\right)^2}}} \quad (12.3.174)$$

what we write under traditional condensed form:

$$t=\gamma\tau \quad (12.3.175)$$

where τ is obviously the "proper time".

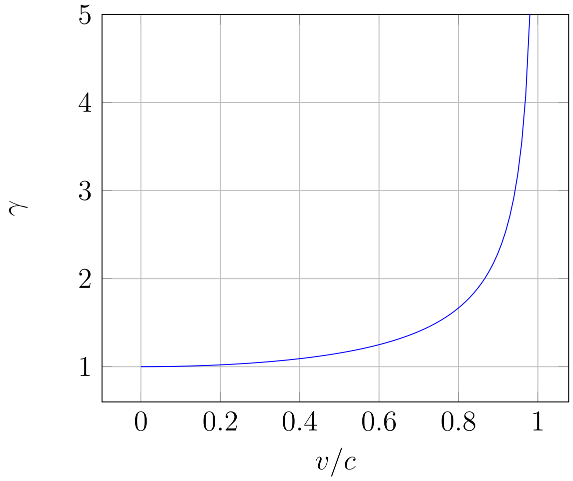


Figure 12.199: Lorentz factor time dilatation function trend

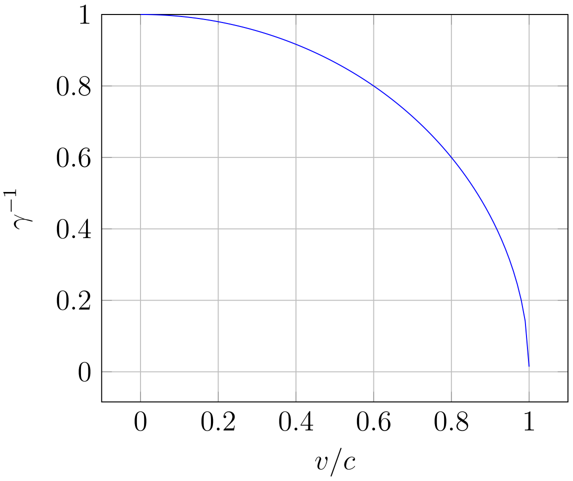

Figure 12.200: Lorentz length contraction function (reminder)

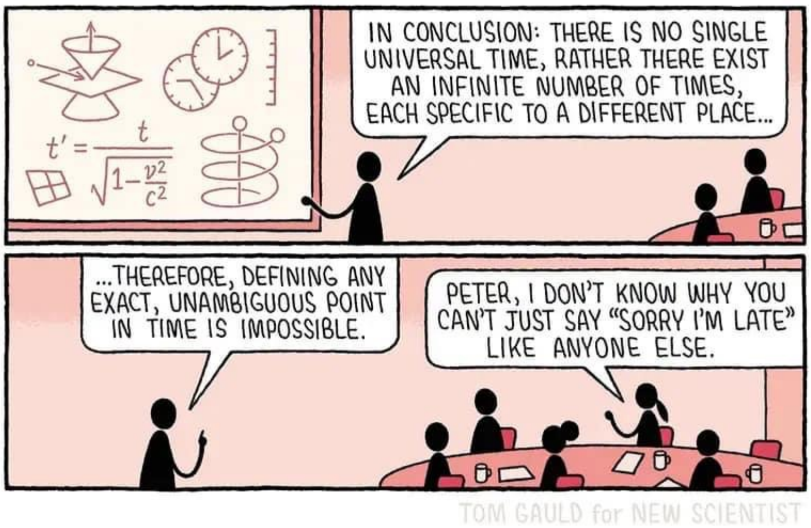
We also deduce taking an infinitesimal time element:

$$\frac{\mathrm{d}t}{\mathrm{d}t'}=\frac{1}{\sqrt{1-\dfrac{v^2}{c^2}}} \quad (12.3.176)$$

So the observer O (stationary) measures a time interval much larger than that one measured in the moving repository where the phenomenon takes place as it moves quickly. The time in the fixed repository (thus the "proper time" of the fixed reference frame!) seems like dilated compared to that in occurring in the mobile reference frame (that is to say relatively to the "proper time" of mobile reference frame!).

The conclusion is that there is no single universal time, rather there exist an infinite number of times, each specific to a different reference frame... therefore, defining any exact, unambiguous point in time is impossible (as far as we know today...)!



$t' = \frac{t}{\sqrt{1-\frac{v^2}{c^2}}}$
IN CONCLUSION: THERE IS NO SINGLE UNIVERSAL TIME, RATHER THERE EXIST AN INFINITE NUMBER OF TIMES, EACH SPECIFIC TO A DIFFERENT PLACE...
...THEREFORE, DEFINING ANY EXACT, UNAMBIGUOUS POINT IN TIME IS IMPOSSIBLE.
PETER, I DON'T KNOW WHY YOU CAN'T JUST SAY "SORRY I'M LATE" LIKE ANYONE ELSE.
TOM GAULD for NEW SCIENTIST

There are a few quite solid experimental direct evidence of relativistic lorentz time contraction. Like the variation of the rate of decay of mesotrons with momentum (see [468]) or the measurements of relativistic time dilatation for positive and negative muons in a circular orbit (see [37]). But we also have experimental evidence with atom clocks like the the study of the rate of a moving atomic clock (see [280] or [281]) or test of relativistic time dilation with fast optical atomic clocks at different velocities (see [461]) or with optical fiber connected to atomic clocks (see [137]). And to finish this list, we also have experimental evidence with optical clocks (see [99]).

Caution! A common error in Special Relativity is to think that time dilation is physical/real, i.e. the people (pr particles) moving will age more slowly. But that's wrong in Special Relativity (but not in General Relativity!) and for exactly the same reasons as for the length dilatation (you just have to consider the axis of space ct instead of the axis of pure time t).

12.3.2.8.1 Lewis Carrol Epstein interpretation

Let us now introduce a quite rare interpretation of time dilation and the fact that we can't move faster than line that Lewis Carrol Epstein liked to explain as following: «*The reason you can't go faster than light is that you can't go slower than light either. You're always going the speed of light. When you're "standing still" you're using all your speed to move through time from past to future. When your are "moving" you're using part of your speed to move through space, so there is less of it moving your through time.*»

If the quote of Lewis isn't crystal clear for you it's quite normal. Doing the maths will help!

The relevant formula for this is:

$$\beta^2+\frac{1}{\gamma^2}=1 \tag{12.3.177}$$

where for reminder $\beta=v/c$ is the ratio of the observed object's speed to the speed of light and:

$$\frac{1}{\gamma}=\sqrt{1-\frac{v^2}{c^2}} \tag{12.3.178}$$

is the reciprocal of the Fitzgerald factor.

Now remember that proper time τ is related to coordinate time t by the relation:

$$\tau=\frac{t}{\gamma} \tag{12.3.179}$$

Now let us take advantage what we just reminded by multiplying the reciprocal of the Fitzgerald factor by the speed of light and defining a new quantity that in essence tells us the "speed of aging" in the same dimensional units as speed (in space):

$$\frac{c}{\gamma}\equiv v_\tau \tag{12.3.180}$$

Here the $\equiv$ symbol means "is defined as" and v_τ is a quantity that could be named "motion in proper time". Now let's go back to the equation that related the proper time to coordinate time $\tau=t/\gamma$ and multiply both sides by the speed of light. Then we get:

$$c\tau=c\frac{t}{\gamma}=v_\tau t \tag{12.3.181}$$

Compare this to the classical motion in space, $d=vt$, we see that the two are exactly analogous: evidently the quantity $c\tau$ is analogous to a distance. Let us now consider the relationship we started off with, that for recall is:

$$\beta^2+\frac{1}{\gamma^2}=1 \tag{12.3.182}$$

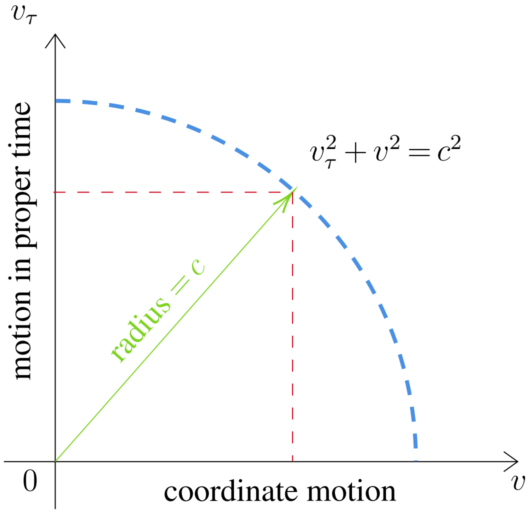
If we multiply both sides by the speed of light squared c^2 we then get:

$$c^2\beta^2+\frac{c^2}{\gamma^2}=c^2 \tag{12.3.183}$$

or, using $v = c\beta$ and the above definition of "motion in proper time":

$$v^2 + v_\tau^2 = c^2 \tag{12.3.184}$$

As the reader can see it, that's simply the Pythagorean theorem and can therefore be represented typically in the quarter of a circle (as in practice only positive speed are of interest).



This is it! Every object travels at the speed of light, but for objects that don't travel at the speed of light in space, it is distributed over motion in space and "motion in proper time". Indeed, notice that if $v = 0$ then the above reduces to:

$$v_\tau = c \tag{12.3.185}$$

This means that, right now, as you are sitting looking at your screen, you are travelling at the speed of light! The reason you don't notice this is that your motion is entirely distributed over "motion in proper time". Since you can never be in motion with respect to yourself, you always travel at the maximum speed in proper time in your rest frame. But when something travels in space relative to you, then their motion, as observed by you, is "redistributed" over motion in space, so, as observed by you, they won't travel as fast in proper time as you do, which is to say, you observe them to "age" more slowly than you do, and we come back to the above relationship between proper time and coordinate time.

Let me now finally address why we can't break the speed of light in space. Well, to break it, you have to first reach it. So why can't we, or any other space-time observer, reach the speed of light in space? If we follow the above chain of reasoning we are now in an excellent position to rephrase the question into an equivalent one that may get us closer to a satisfying answer, namely: Why can't we, or any other space-time observer, travel at zero "motion in proper time"?

Let us consider what it means to travel at zero "motion in proper time". For objects that travel at $v = c$ or equivalently:

$$v_\tau = 0 \tag{12.3.186}$$

if such objects had a space-time rest frame, then in their rest frame the moment they are observed to come into existence would be separated by the moment they go out of existence by exactly zero seconds. This follows directly from the standard relation:

$$c\tau = c\frac{t}{\gamma} = t\sqrt{c^2 - c^2} = 0 \qquad (12.3.187)$$

that relates proper time to coordinate, or we can simply conceptualize it from the fact that for $v_\tau = 0$ no proper time interval is traversed. This means, in particular, that if such objects had a space-time rest frame, then they would observe their own duration of existence in space-time to be exactly zero! (it is kinda a "photon existence paradox" because naively, if we didn't already know that photons exist, then surely this would have been used as an argument to justify why they could not exist...).

Now imagine that we could somehow transform to a frame in which our motion in proper time is zero. Then you would be sharing our rest frame with objects that observe their own duration of existence in space-time to be exactly zero. But, we already had a non-zero duration of existence in space-time before we transformed to that frame. As a result, if it was possible for us to reach the speed of light, then an observer could in our frame observe their own duration of existence in space-time to be both zero and non-zero. This is a contradiction, so that means we cannot transform to a frame in which our motion in proper time is zero, which is to say, we (or any other space-time observer) cannot transform to a frame in which we travel at the speed of light, and since we cannot reach the speed of light in space, we cannot break it, either, since in order to break it, we have to reach it first.

This can be illustrated in a schematic way (quarter of circle) named the "cosmic speedometer".

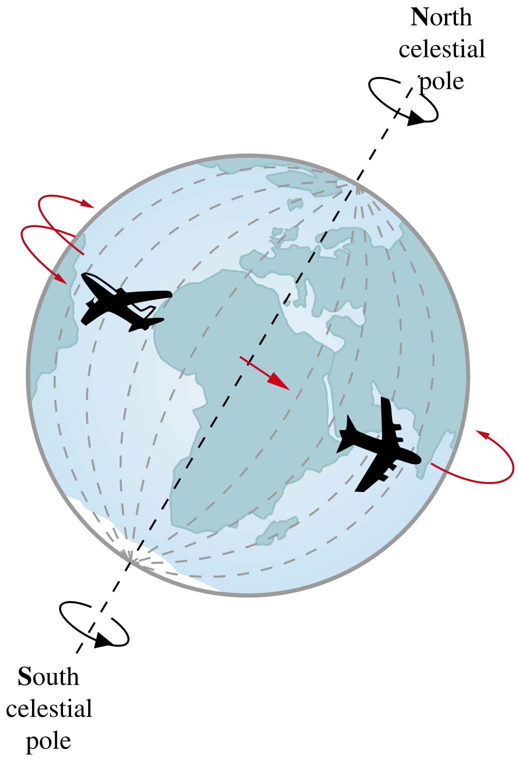
Let us see now two applied examples of what we have seen so far[40] that are so famous that they have their own name...:

12.3.2.8.2 Hafele–Keating experiment (special relativity version)

In 11971 (holocene calendar), direct experimental verification of time dilation was performed. Two airplanes in whose had been placed a cesium atomic clock during their regular commercial flights (one flying to the east, the other to west) compared their clocks to a third atomic clock remained on the ground (see [220]). This experiment made famous by time is named today "Hafele-Keating experiment" (Joseph C. Hafele, a physicist, and Richard E. Keating, an astronomer).

---

[40] Apart from these two famous examples, time dilatation helps particle physicists at the LHC (CERN) to track some particles during high energy collisions that have a too short lifetime to be correctly observed and studied but that thanks to their high speed have a significant longer proper life time due to time dilatation! Therefore with time dilatation particle physicists have the opportunity to study some specific particles properties what would not be possible without! Hourrra!



Because the Hafele–Keating experiment has been reproduced by increasingly accurate methods, there has been a consensus among physicists since at least the 11970s (holocene calendar) that the relativistic predictions of gravitational and kinematic effects on time have been conclusively verified. Criticisms of the experiment did not address the subsequent verification of the result by more accurate methods, and have been shown to be in error.

The idea is obviously that in a frame of reference at rest with respect to the center of the Earth, a clock aboard the plane moving eastward, in the direction of the Earth's rotation, has a greater velocity (resulting in a relative time loss) than one that remained on the ground, while a clock aboard the plane moving westward, against the Earth's rotation, had a lower velocity than one on the ground.

The plane flying eastward lost 59 [ns] while the plane flying westward gained 273 [ns] (the Earth rotates on itself in a day, from West to East. It was therefore measured a total difference:

$$\Delta t = t_{\text{East}} - t_{\text{West}} = (-59) - (+273) \cong -332\,[\text{ns}] \tag{12.3.188}$$

between the two clocks and this difference is even statistically significantly greater than that the one implied by Special Relativity (see detailed calculations just below).

Let us analyse the experience considering that all repositories are inertial (thus eliminating General Relativity).

Remark

Strictly speaking, the effect of General Relativity (slowing of clocks depending on the altitude in accordance with Einstein's effect proved in the section of General Relativity at page 5796) is absolutely not negligible since it is equivalent in amplitude that of Special Relativity. This is why we will study this experiment again in the section of General

Relativity.

Let us consider for our study three inertial reference points, one at the North Pole, one on Earth (elsewhere apart from the North Pole in the idea!) and one in a plane. The time intervals $t_{\text{North}}, t_{\text{Earth}}$ and t_{plane} respectively (which we will abbreviated t_N, t_E, t_P for the following developments), are connected by the previously proven relations (so the North pole is taken as the reference at rest in this experience and therefore the reference proper time!):

$$t_N = \gamma_E t_E = \gamma_P t_P \tag{12.3.189}$$

where we have:

$$\gamma_T = \frac{1}{\sqrt{1-\left(\frac{v_E}{c}\right)^2}} \qquad \gamma_P = \frac{1}{\sqrt{1-\left(\frac{v_P}{c}\right)^2}} \tag{12.3.190}$$

The repository on Earth and in the plane so have equation relative speeds v_E and v_P relative to the North Pole. The time by plane and on Earth are then linked by:

$$t_P = \frac{\gamma_E}{\gamma_P} t_E = \frac{\sqrt{1-\left(\frac{v_E}{c}\right)^2}}{\sqrt{1-\left(\frac{v_P}{c}\right)^2}} t_T \tag{12.3.191}$$

We will now rewrite this relation:

$$t_P = \frac{\gamma_E}{\gamma_P} t_T = \sqrt{\frac{1-(v_P/c)^2-(v_E/c)^2+(v_P/c)^2}{1-(v_P/c)^2}} t_E = \sqrt{1+\frac{(v_P/c)^2-(v_E/c)^2}{1-(v_P/c)^2}} t_E \tag{12.3.192}$$

We will accept the following approximation:

$$t_P = \frac{\gamma_E}{\gamma_P} t_E \cong \sqrt{1+[(v_P/c)^2-(v_E/c)^2]} t_E \tag{12.3.193}$$

where we have assumed that at the denominator:

$$(v_P/c)^2 \ll 1 \tag{12.3.194}$$

For square roots whose value is anyway close to 1 (since c is much larger than the considered relative speeds), we can do a Maclaurin expansion to the second order as x approaches zero (see section Sequences and Series page 1703):

$$\sqrt{1+x} \cong (1+x) + \frac{1}{1!}\frac{1}{2\sqrt{1+a}}(x-a) \underset{a=0}{=} = 1 + \frac{1}{2}x \tag{12.3.195}$$

Then we can write:

$$t_P = \frac{\gamma_E}{\gamma_P} t_P \cong \left(1+\frac{(v_P/c)^2-(v_E/c)^2}{2}\right) t_E \tag{12.3.196}$$

Thanks to these tricky successive approximations, we can easily write the difference between the two clocks that is then:

$$\Delta t_{AE} = t_P - t_E \cong t_E \frac{(v_P/c)^2-(v_E/c)^2}{2} \tag{12.3.197}$$

According to the initial assumptions, the cruising speed of the two aircraft from the ground is constant and is denoted v. The speed of each plane (!non-relativistic according to the preceding approximations) is then:

$$v_P=v_E-v \tag{12.3.198}$$

for the plane going eastwards and:

$$v_P=v_E+v \tag{12.3.199}$$

for the aircraft going respectively westward. So:

$$\begin{aligned}\Delta t=t_{\text{East}}-t_{\text{West}}&=\left(t_E\frac{\left(\dfrac{v_E-v}{c}\right)^2-\left(\dfrac{v_E}{c}\right)^2}{2}\right)-\left(t_E\frac{\left(\dfrac{v_E+v}{c}\right)^2-\left(\dfrac{v_E}{c}\right)^2}{2}\right)\\&=t_E\left(\frac{\left(\dfrac{v_E-v}{c}\right)^2}{2}-\frac{\left(\dfrac{v_E+v}{c}\right)^2}{2}\right)\end{aligned} \tag{12.3.200}$$

We will consider that (it's pretty rough ...):

$$\frac{v_E^2}{c^2}\ll\frac{2vv_E}{c^2}\frac{v^2}{c^2}\quad\ll\frac{2vv_E}{c^2} \tag{12.3.201}$$

So it remains:

$$\Delta t=t_{\text{East}}-t_{\text{West}}\cong t_E\left[\frac{-\dfrac{2vv_E}{c^2}}{2}-\frac{\dfrac{2vv_E}{c^2}}{2}\right]=t_E\left(-\frac{vv_E}{c^2}-\frac{vv_E}{c^2}\right)=-t_E\frac{2vv_E}{c^2} \tag{12.3.202}$$

We see well that obviously with the previous approximations we lost the asymmetry of time dilatation between East and West. The reader that this should disturb can then apply directly the numerical values in the prior previous relation.

The previous result that we got with all successive approximations already leaded us to see formally and quickly that the sign of the result will be in agreement with experimental results.

For a practical numerical application, we will take the constant speed of the commercial planes at that time that was:

$$v\cong 220\,[\text{m}\cdot\text{s}^{-1}] \tag{12.3.203}$$

and the total time travel of planes was of 41 hours according to the measurement at the ground, thus:

$$t_E=147,600\,[\text{s}] \tag{12.3.204}$$

and a point at the equator of the Earth's surface moves at the speed:

$$v_E=\frac{2\pi R}{t_{\text{day}}} \tag{12.3.205}$$

where the Earth's radius being of $6,371$ [km] (this suppose that the plans are above the equator radius). We then have applying all that numerical values:

$$\Delta t = -t_E \frac{2vv_E}{c^2} = -147,600 \frac{2 \cdot 200 \dfrac{2\pi \cdot 6,371,000}{24 \cdot 60 \cdot 60}}{299,792,458^2} = -147,600 \frac{2 \cdot 220 \cdot 463}{299,792,458^2} \cong 334\,[\text{ns}] \tag{12.3.206}$$

which leads to a result very close to the measurement that was performed.

And using directly the non-approximate version:

$$\begin{aligned}\Delta t = t_{\text{East}} - t_{\text{West}} &= \left(t_E \frac{\left(\dfrac{v_E - v}{c}\right)^2 - \left(\dfrac{v_E}{c}\right)^2}{2} \right) - \left(t_E \frac{\left(\dfrac{v_E + v}{c}\right)^2 - \left(\dfrac{v_E}{c}\right)^2}{2} \right) \\ &= -92 + (+173) = -265\,[\text{ns}]\end{aligned} \tag{12.3.207}$$

where we took this time the speed of the Earth at latitude consistent with the experience in 11971 (holocene calendar):

$$v_E = \frac{2\pi R \cos(38^\circ)}{t_{\text{day}}} \cong 365\,[\text{m} \cdot \text{s}^{-1}] \tag{12.3.208}$$

So we see that the result is therefore not very consistent with the experience! Indeed, we must now consider in that approximated case the time dilatation due to gravity. We'll have to use the Einstein's effect relation proved in the section of General Relativity (see page 5796) for approximated locally flat space:

$$\frac{\Delta t}{t_0} = \frac{gh}{c^2} \tag{12.3.209}$$

which expresses for recall the that at the ground time flows slower than the time at altitude h.

According to the records of the experiment, the aircraft flew at $10,000$ [m] above sea level. What gives (the acceleration g is not the same on the ground level than in altitude for recall!) and acceleration of time of:

$$\Delta t = \frac{gh}{c^2} t_0 \cong \frac{9.5 \cdot 10,000}{299,792,458^2} \cdot 147,600 = +156\,[\text{ns}] \tag{12.3.210}$$

But, we see that the two aircraft were both at the same height, we always have:

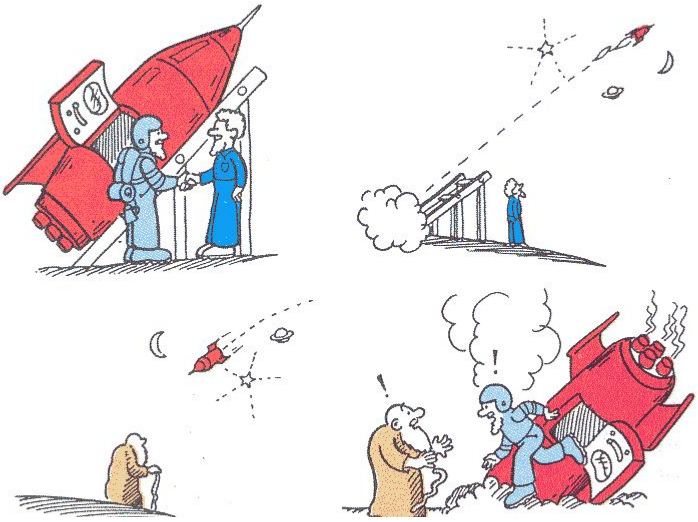
$$\Delta t = t_{\text{East}} - t_{\text{West}} = (-92 - 156) - (+173 - 156) = -265\,[\text{ns}] \tag{12.3.211}$$

So either there are other effects, of the order of General Relativity, which should be taken into account to explain the 67 [ns] of difference to the experience, or it is a accuracy problem of the time accuracy of the time clock at the time of the experiment.

In fact, we will see a detailed study of this experience in the section of General Relativity and see that the theoretical values are in very good agreement with experimental results.

12.3.2.8.3 Twins paradox

The twin paradox is a thought experiment in Special Relativity involving identical twins, one of whom makes a journey into space in a high-speed rocket and returns home to find that the twin who remained on Earth has aged more. This result appears puzzling because each twin sees the other twin as moving, and so, according to an incorrect and naive application of time dilation and the principle of relativity, each should paradoxically find the other to have aged more slowly. However, this scenario can be resolved (again contrary to a popular misconception) within the standard framework of Special Relativity: the travelling twin's trajectory involves two different inertial frames, one for the outbound journey and one for the inbound journey, and so there is no symmetry between the space-time paths of the two twins. Therefore, the twin paradox is not a paradox in the sense of a logical contradiction.



We can already consider the famous twin paradox in the framework of Special Relativity to show that the twin paradox does not only apply to non inertial systems. This is a rough approach (knowing that we will rigorously discussed the subject in the section of General Relativity).

Let us consider a rocket taking off at time t zero of the Earth and accelerating to 20 times the acceleration of Earth's gravity g up to a cruising speed of 90% the speed of light c. Let us suppose that the rocket continues at this speed during a terrestrial year and decelerate with the same intensity to resume its journey to Earth and accelerates again for its approach to the Earth and decelerate once again to its final zero velocity:

$$\Delta v=a\Delta t=20g(\Delta t_{\text{acc.}})=0.9c\Rightarrow\Delta t_{\text{acc.}}=\sqrt{\frac{0.9c}{20g}}=\sqrt{0.9c}20\cdot\cong 1.35\cdot 10^6\cong 15.6\,[\text{days}] \tag{12.3.212}$$

Thus, the total proper time spent for a human remained on Earth is:

$$\Delta {t'}_T\cong 15.6\cdot 4+365\cdot 2\cong 792.4\,[\text{days}] \tag{12.3.213}$$

For the traveller in the rocket, the proper time during the acceleration phase will be given roughly by:

$$\mathrm{d}{t'}_{a,f}=\sqrt{1-\frac{v^2}{c^2}}\mathrm{d}t=\sqrt{1-\frac{1}{c^2}(v)^2}\mathrm{d}t=\sqrt{1-\frac{1}{c^2}(gt)^2}\mathrm{d}t=\sqrt{1-\frac{g^2}{c^2}t^2}\mathrm{d}t \tag{12.3.214}$$

Thus by integrating (using the usual primitive proved in the section of Differential and Integral Calculus page 1534) for one of the phase of acceleration of the rocket it gives:

$$\begin{aligned}\Delta t'_{a,f}&=\int\limits_0^{\Delta t_{\text{acc}}}\sqrt{1-\frac{g^2}{c^2}t^2}\mathrm{d}t=\frac{g}{c}\int\limits_0^{\Delta t_{\text{acc}}}\sqrt{\left(\frac{c}{g}\right)^2-t^2}\mathrm{d}t\\&=\left[\frac{\left(\frac{c}{g}\right)^2}{2}\arcsin\left(\frac{t}{\frac{c}{g}}\right)+\frac{t}{2}\sqrt{\left(\frac{c}{g}\right)^2-t^2}\right]_0^{1.35\cdot 10^6}\qquad\cong 1.13\cdot 10^6\cong 13.1\,[\text{days}]\end{aligned}\tag{12.3.215}$$

And the proper time for the part with the constant cruising speed:

$$\Delta t'_{\text{cruising},f}=\int\limits_0^{365\,[\text{days}]}\sqrt{1-\frac{v^2}{c^2}}\mathrm{d}t\cong\int\limits_0^{365\,[\text{days}]}\sqrt{1-0.81}\mathrm{d}t=\sqrt{0.19}\int\limits_0^{365\,[\text{days}]}\mathrm{d}t\cong 159.1\,[\text{d}]\tag{12.3.216}$$

And therefore the total proper time in the rocket is:

$$\Delta t'_{\text{cruising},f}\cong 13.1+159.1=370.6\,[\text{days}]\tag{12.3.217}$$

So compared to the person remained on Earth, the one that was in the rocket has aged about half !!! This is a paradox (rather a "sophism" in reality) because we can not accurately apply Special Relativity to non-inertial frames. Nevertheless, even with General Relativity, there is a time difference!

Caution! But we haven't solved the Langevin's paradox here! Because in the framework of Special Relativity both observers can be switched independently. And that's the problem of making the calculations with Special Relativity: the acceleration is relative. That doesn't make sense in real life (even if it's possible on the paper) because in reality, one of the observer will feel an acceleration and deceleration when the other one won't. And that's what General Relativity can deal with: it makes acceleration absolute!

12.3.2.9 Apparent relativistic mass

First the reader must take careful (!!) The title is misleading by tradition! We will see why a little further below.

Meanwhile, imagine a frontal collision between two identical objects (1) and (2) having in the repository R_0 equal but opposite speeds. We will assume that the collision is elastic, that is to say that the kinetic energy and momentum are conserved.

Before the shock (collision), the components of objects speeds (1) and (2) are:

$$1=\begin{pmatrix}u_1\\v_1\end{pmatrix}\qquad 2=\begin{pmatrix}u_2\\v_2\end{pmatrix}=\begin{pmatrix}-u_1\\-v_1\end{pmatrix}\tag{12.3.218}$$

as shown below:

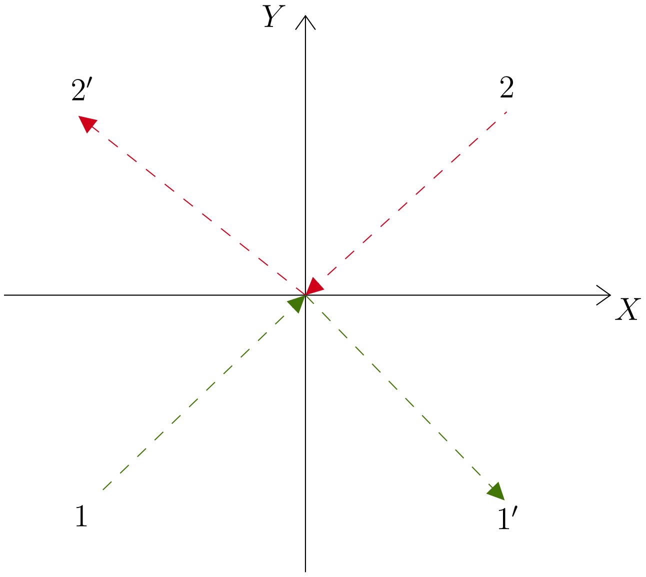


Figure 12.201: Configuration for the study of the apparent relativistic mass variation seen from R_0

After the collision, we have:

$$1'=\begin{pmatrix}u'_1\\v'_1\end{pmatrix}=\begin{pmatrix}u_1\\-v'_1\end{pmatrix}\qquad 2'=\begin{pmatrix}u'_2\\v'_2\end{pmatrix}=\begin{pmatrix}u_2\\-v_2\end{pmatrix}=\begin{pmatrix}-u_1\\v_1\end{pmatrix}\tag{12.3.219}$$

We will now apply the following Lorentz transformation:

- We give ourselves another repository R and assume that the repositories R_0 and R are in uniform translation speed u_1 along the x-axis in the positive direction (that is to say in the same direction and at the same horizontal speed than the particle (1)).
- For our particle (1) its trajectory became such is present not visible speed anymore along the x-axis.

Let's go! Let us place ourselves in repository R that moves relative to R_0 with the speed u_1 following the x-axis, the components of the speeds in this repository are ten before the collision:

$$1=\begin{pmatrix}U_1\\V_1\end{pmatrix}\qquad 2=\begin{pmatrix}U_2\\V_2\end{pmatrix}\tag{12.3.220}$$

and after the collision:

$$1'=\begin{pmatrix}U'_1\\V'_1\end{pmatrix}\qquad 2'=\begin{pmatrix}U'_2\\V'_2\end{pmatrix}\tag{12.3.221}$$

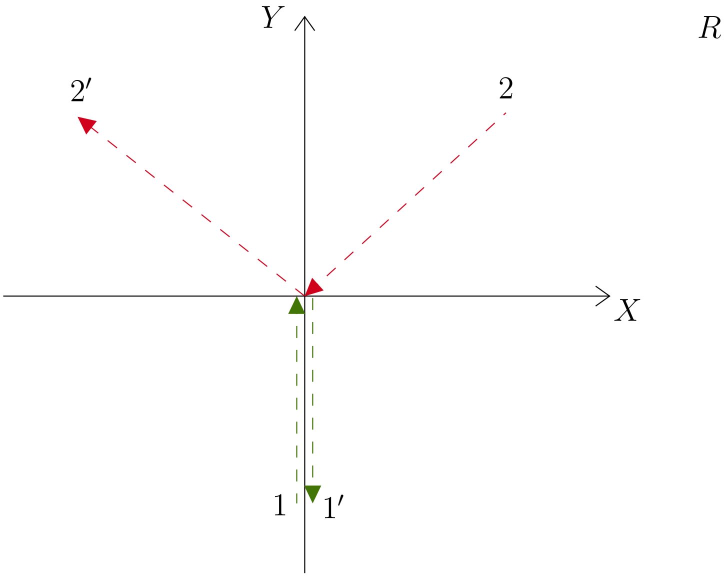

Figure 12.202: **Configuration for the study of the apparent relativistic mass variation seen from R**

So we have trivially in the reference frame R:

$$U'_1=U_1=0 \qquad V'_1=-V_1 \qquad U'_2=U_2 \qquad V'_2=-V_2 \tag{12.3.222}$$

but by applying the law of composition of speeds proved earlier above:

$$V'=\frac{x'}{t'}=\frac{v_2-v_1}{1-\dfrac{v_1v_2}{c^2}} \tag{12.3.223}$$

for the components of the horizontal axis we always have in the reference frame R:

$$\begin{aligned}&U_1=0\\&U_2=\frac{u_2-u_1}{1-\dfrac{u_2u_1}{c^2}}=\frac{(-u_1)-u_1}{1-\dfrac{(-u_1)(u_1)}{c^2}}=-\frac{2u_1}{1+\dfrac{u_1^2}{c^2}}\end{aligned} \tag{12.3.224}$$

and for the vertical movement, we have seen earlier above that:

$$v'_y=\frac{v_y}{\gamma\left(1-\dfrac{v}{c^2}v_x\right)} \tag{12.3.225}$$

Therefore we get:

$$\begin{aligned}&V_1=\frac{v_1}{\gamma\left(1-\dfrac{u_1}{c^2}u_1\right)}=\frac{v_1}{\gamma\left(1-\dfrac{u_1^2}{c^2}\right)}=\frac{\sqrt{1-\dfrac{u_1^2}{c^2}}v_1}{1-\dfrac{u_1^2}{c^2}}=\frac{v_1}{\sqrt{1-\dfrac{u_1^2}{c^2}}}=v_1\gamma\\&V_2=\frac{v_2}{\gamma\left(1-\dfrac{u_1}{c^2}u_2\right)}=\frac{v_2}{\gamma\left(1-\dfrac{u_1u_2}{c^2}\right)}=\frac{-v_1}{\gamma}\frac{1}{1+\dfrac{u_1^2}{c^2}}\end{aligned} \tag{12.3.226}$$

Passing from R_0 to R, the component following y of the total momentum must remain zero (as it was the case in R_0 initially). But:

$$V_1+V_2=\frac{v_1}{\gamma}\frac{1}{1-\dfrac{u_1^2}{c^2}}-\frac{v_1}{\gamma}\frac{1}{1+\dfrac{u_1^2}{c^2}}\neq 0 \tag{12.3.227}$$

To break this deadlock, we must admit that the respective apparent masses m_1 and m_2 may not be identical in R. So that brings us to require that:

$$|m_1V_1|=\frac{m_1v_1}{\gamma}\frac{1}{1-\dfrac{u_1^2}{c^2}}=|m_2V_2|=\frac{m_2v_1}{\gamma}\frac{1}{1+\dfrac{u_1^2}{c^2}} \tag{12.3.228}$$

which leads us to:

$$\frac{m_2}{m_1}=\frac{1+\dfrac{u_1^2}{c^2}}{1-\dfrac{u_1^2}{c^2}} \tag{12.3.229}$$

In R, the square of the norm of the two objects speeds gives:

$$\begin{gathered}U_1^2+V_1^2=V_1^2=v_1^2\gamma^2\\ U_2^2+V_2^2=\left(\frac{-2u_1}{1+\dfrac{u_1^2}{c^2}}\right)^2+\left(\frac{-v_1}{\gamma}\frac{1}{1+\dfrac{u_1^2}{c^2}}\right)^2=\frac{4u_1^2+v_1^2\left(1-\dfrac{u_1^2}{c^2}\right)}{\left(1+\dfrac{u_1^2}{c^2}\right)^2}=\frac{4u_1^2+V_1^2\left(1-\dfrac{u_1^2}{c^2}\right)^2}{\left(1+\dfrac{u_1^2}{c^2}\right)^2}\end{gathered} \tag{12.3.230}$$

The last relation can be written:

$$\frac{U_2^2+V_2^2}{c^2}\left(1+\frac{u_1^2}{c^2}\right)^2\left(1+\frac{u_1^2}{c^2}\right)^2=4\frac{u_1^2}{c^2}+\frac{V_1^2}{c^2}\left(1-\frac{u_1^2}{c^2}\right)^2=\left(1+\frac{u_1^2}{c^2}\right)^2-\left(1-\frac{u_1^2}{c^2}\right)^2+\frac{V_1^2}{c^2}\left(1-\frac{u_1^2}{c^2}\right)^2 \tag{12.3.231}$$

so that after rearrangement and factorization we get:

$$\left(\frac{U_2^2+V_2^2}{c^2}-1\right)\left(1+\frac{u_1^2}{c^2}\right)^2=\left(1-\frac{u_1^2}{c^2}\right)\left(\frac{V_1^2}{c^2}-1\right) \tag{12.3.232}$$

Therefore:

$$\frac{\left(1+\dfrac{u_1^2}{c^2}\right)^2}{\left(1-\dfrac{u_1^2}{c^2}\right)^2}=\frac{1-\dfrac{V_1^2}{c^2}}{1-\dfrac{U_2^2+V_2^2}{c^2}}=\frac{\Gamma_2^2}{\Gamma_1^2} \tag{12.3.233}$$

We thus found:

$$\frac{m_2}{m_1}=\frac{1+\dfrac{u_1^2}{c^2}}{1-\dfrac{u_1^2}{c^2}}=\frac{\Gamma_2}{\Gamma_1}\Leftrightarrow\frac{m_2}{\Gamma_2}=\frac{m_1}{\Gamma_1^2} \tag{12.3.234}$$

In the case as assumed above where both object are identical we will put $m_1 = m_2 = m_0$ and therefore:

$$\frac{m_0}{\Gamma_2} = \frac{m_0}{\Gamma_1} \tag{12.3.235}$$

And we will put them as an apparent relativistic mass denoted simply by m such that:

$$m = \frac{m_0}{\Gamma_2} = \frac{m_0}{\Gamma_1} \tag{12.3.236}$$

And as V_1^2 and $U_2^2 + V_2^2$ are simply the square norm of the velocity, we can write:

$$m = \frac{m_0}{\Gamma_2} = \frac{m_0}{\Gamma_1} = \gamma m_0 \tag{12.3.237}$$

So that finally:

$$\boxed{m = \gamma m_0 = \frac{m_0}{\sqrt{1 - \dfrac{v^2}{c^2}}}} \tag{12.3.238}$$

So we see that when $v = 0$, we have $m = m_0$ this is why we name m_0 the "rest mass" or "invariant mass".

Since the mass is a function of v (at least in appearance), some physicists note the rest mass as a function, that is to say: $m(0)$. But it is rather more common to use the notation m_0 to not have to tract too many parentheses in developments...

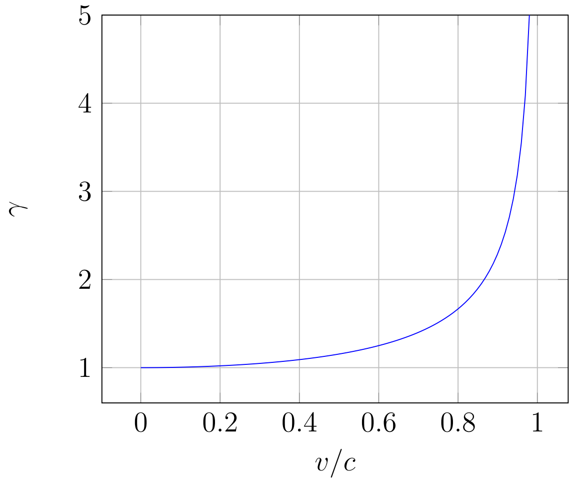

Figure 12.203: **Lorentz factor mass (and time) dilatation function trend**

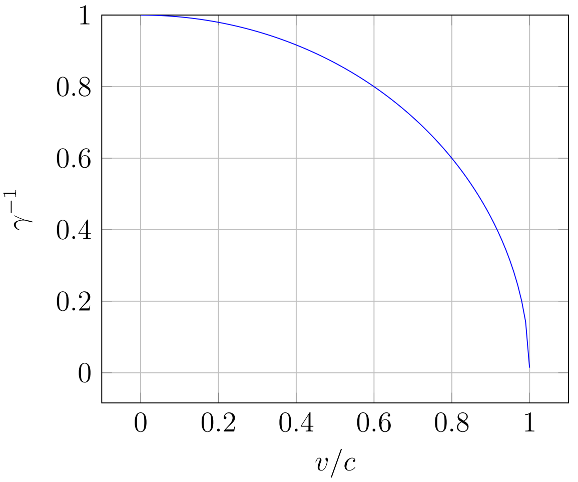

Figure 12.204: **Lorentz factor length contraction function trend (reminder)**

As the Michelson-Morley factor γ tends to infinity when the speed v approaches the speed c of light in a vacuum we have an additional reason to say that c is the upper limit assigned to the speed of any material object otherwise the apparent mass m would be infinite also, which is consistent with both the experience and the consequences already formulated by the Lorentz transformations!!!

It already follows an important conclusion: there are therefore two types of particles, those with a mass and will never go to the speed of light (as it then takes an infinite energy to get them there following our previous result), and those having a zero mass and which will therefore necessarily be at the speed of light.

As we will see it in the section of Quantum Field Theory interaction forces are short-range precisely because of the uncertainty principle and of the above statement. The greater the distance is between large particles that interacts together, the more time will be longer and therefore the smaller will be the energy involved. But in the case where the particle of interaction have no mass, the "force" is a long range one.

12.3.2.9.1 Why is Gold yellow?

One of the most famous use of Special Relativity in everyday life, and especially of relativistic mass, is very likely the legendary argument that gold should have a silvery shine just like other metals and the reason why it appears golden is said to be explained quite well by using Special Relativity! We will see what is the underlying idea, even if sadly, it's quite an urban legend as the reality is much more complex and involves material physics (see our explanations at the end).

One of the most important and familiar results of Special Relativity is that the relativistic mass of the electron increases as:

$$m_{\text{rel}}=\frac{m_e}{\sqrt{1-(v_e/c)^2}} \tag{12.3.239}$$

where m_e, v_e, c are the electron rest mass, velocity of the electron, and speed of light respectively.

This has an immediate implication on the Bohr radius (r_0) (see section Corpuscular Quantum Physics page 4630), which is given by:

$$r_0=\frac{\hbar}{m_e c\alpha} \tag{12.3.240}$$

where $\hbar$ is the reduced Planck's constant, and α is the fine-structure constant ($\alpha=\frac{1}{4\pi\varepsilon_0}\frac{e^2}{\hbar c}$).

If one substitutes the "relativistic mass" into the equation for the Bohr radius it can be written:

$$r_{\text{rel}}=\frac{\hbar\sqrt{1-(v_e/c)^2}}{m_e c\alpha} \tag{12.3.241}$$

It follows that:

$$\frac{r_{\text{rel}}}{r_0}=\sqrt{1-(v_e/c)^2} \tag{12.3.242}$$

The above ratio of the relativistic and nonrelativistic Bohr radii has been plotted as a function of the electron velocity:

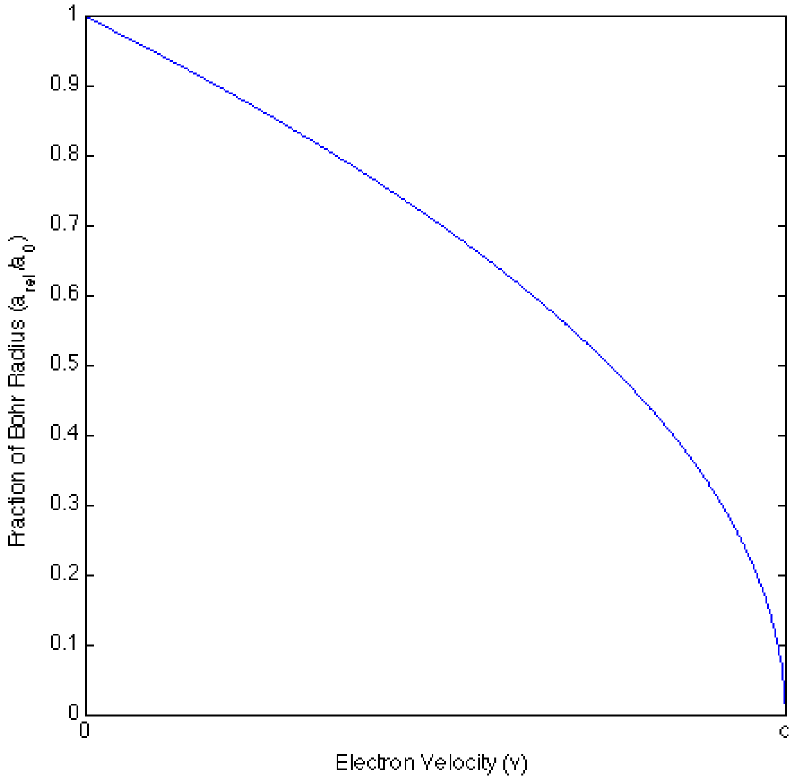

Figure 12.205: **Ratio of relativistic and nonrelativistic Bohr radii as a function of electron velocity (source: Wikipedia)**

Notice how the relativistic model shows the radius decreases with increasing velocity.

In the Bohr model, the angular momentum is given as we have already seen it by $m_e\omega_e r^2 = m_e v_e r = n\hbar$ (see section Corpuscular Quantum Physics page 4629). So multiplying both sides of the explicit definition of Bohr radius:

$$r = \frac{n^2\hbar^2 4\pi\varepsilon_0}{m_e Z e^2} \tag{12.3.243}$$

by $m_e v_e$, we get:

$$n\hbar = \frac{m_e v_e n^2\hbar^2 4\pi\varepsilon_0}{m_e Z e^2} \tag{12.3.244}$$

Simplifying and rearranging gives us:

$$v_e = \frac{Ze^2}{4\pi\varepsilon_0\hbar n} \tag{12.3.245}$$

Dividing both sides by c:

$$\frac{v_e}{c} = \frac{Ze^2}{4\pi\varepsilon_0\hbar c n} \tag{12.3.246}$$

Substituting this into the expression for the Bohr ratio mentioned above gives:

$$\frac{r_{\text{rel}}}{r_0} = \sqrt{1-\left(\frac{Ze^2}{4\pi\varepsilon_0\hbar c n}\right)^2} \tag{12.3.247}$$

At this point one can see that a low value of n and a high value of Z results in $\frac{r_{\text{rel}}}{r_0} \to 0$. This fits with intuition: electrons with lower principal quantum numbers will have a higher probability density of being nearer to the nucleus. A nucleus with a large charge will cause an electron to have a high velocity. A higher electron velocity means an increased electron relativistic mass, and as a result the electrons will be near the nucleus more of the time and thereby contract the radius for small principal quantum numbers.

For gold with $Z = 79$, $v_e \cong 0.58c$, so the $1s$ electron will be moving at 58% of the speed of light. Plugging this in for v/c in the equation for the relativistic mass, one finds that $m_{\text{rel}} = 1.22m_e$, and in turn putting this in for the Bohr radius above one finds that the radius shrinks by 22%.

The reflectivity (keep in mind that where reflectance is low, absorbance is high and vice-versa) of aluminium (Al), silver (Ag), and gold (Au) is shown in the graph below. The human eye sees electromagnetic radiation with a wavelength near 600 [nm] as yellow. Gold appears yellow because it absorbs blue light more than it absorbs other visible wavelengths of light; the reflected light reaching the eye is therefore lacking in blue compared to the incident light. Since yellow is complementary to blue, this makes a piece of gold under white light appear yellow to human eyes.

The electrons inside gold atom travel at speeds as high as half the speed of light. This causes relativistic effects (length contraction) and shrinks the shells closer to the nucleus such that the energy difference between the outermost shells now corresponds to blue light.

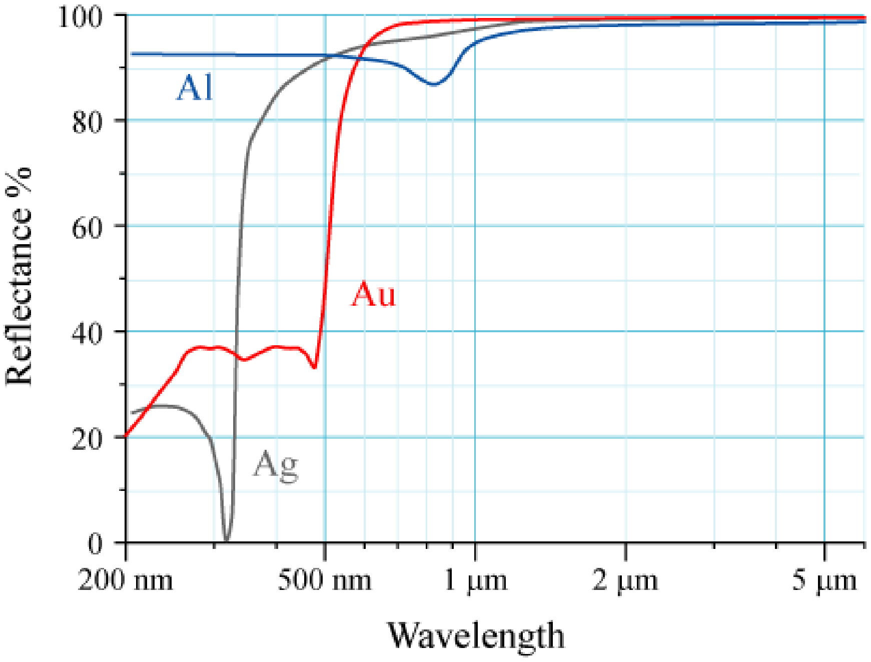

Figure 12.206: Spectral reflectance curves for aluminum, silver and gold metal mirrors (source: Wikipedia, author: Bob Mellish)

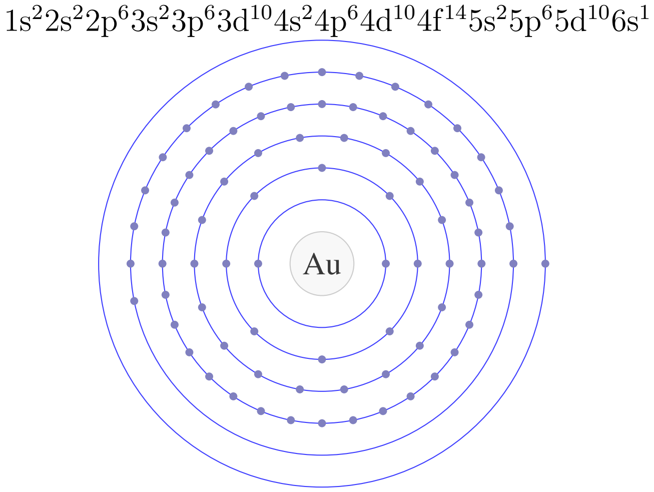
The electronic transition from the $5d$ orbital to the $6s$ orbital is responsible for this absorption.



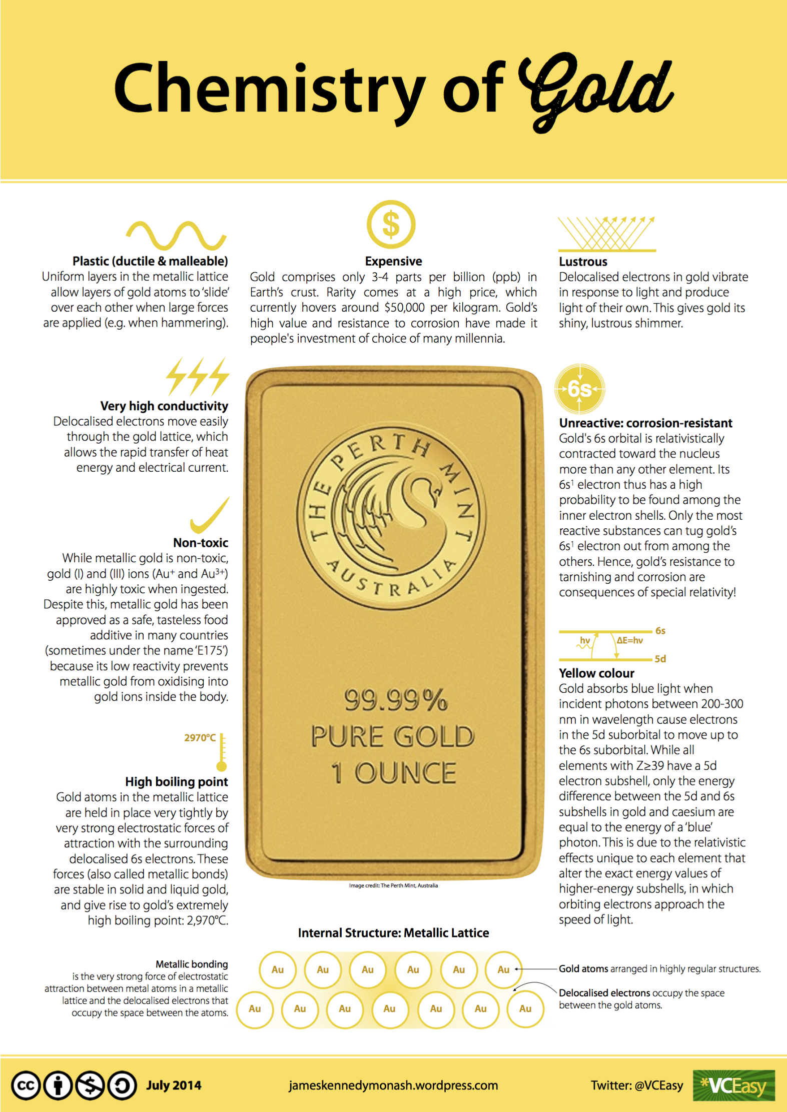
$1s^2 2s^2 2p^6 3s^2 3p^6 3d^{10} 4s^2 4p^6 4d^{10} 4f^{14} 5s^2 5p^6 5d^{10} 6s^1$
Au

Figure 12.207: **Gold Bohr naive model configuration**

When you compare color of pure elements, don't forget to compare only elements of the same column of the periodic table of elements (i.e. having the same electronic structure). Elements that occupy the same column on the periodic table (named a "group") have identical valence electron configurations and consequently behave in a similar fashion chemically!

An analogous transition occurs in silver (^{47}Ag), but the relativistic effects are smaller than in gold. While silver's $4d$ orbital experiences some relativistic expansion and the $5s$ orbital some contraction, the $4d-5s$ distance in silver is much greater than the $5d-6s$ distance in gold. The relativistic effects increase the $5d$ orbital's distance from the atom's nucleus and decrease the $6s$ orbital's distance.

Obviously the reality is much more complex (as always when we use toy models in physics) than using the simple Bohr model and assuming that a single atom behaves identically the same atoms in a bulk material. A robust treatment of the topic would involve Quantum Chemistry techniques (with more and more electrons being added, the difficulties mount rapidly because of screening and other factors) that can't be solved by hand and that would require intensive usage of Numerical Methods. All that means, is that the last few outer electrons of Au see a slightly different potential than they would have if there were no Special Relativity. In the end, given the binding energies for Au compared with Cu and Ag there really is not much difference (highly similar band structure and Fermi surfaces). The color differences of them are all done to the plasmon absorption in the visible, a bulk feature, with slight different plasmon energies for Cu, Ag, and Au. For comparison, Ag has 58.3 and 63.7 [eV], and Cu 75.1 and 73.3 [eV], respectively. So, really, the outer electrons of Au are not particularly different from the outer electrons of the other noble metals as one would expect from their band structures. In a solid, there are many available states above the Fermi surface (essentially a continuum considering all wave vectors $\vec{k}$), and once an electron is put up there it rapidly thermalizes back down through electron-electron and electron-phonon interactions (order picoseconds or less). The atomic physics is just sometimes very different from the material physics!



Chemistry of Gold

Plastic (ductile & malleable)
Uniform layers in the metallic lattice allow layers of gold atoms to 'slide' over each other when large forces are applied (e.g. when hammering).

Expensive
Gold comprises only 3-4 parts per billion (ppb) in Earth's crust. Rarity comes at a high price, which currently hovers around $50,000 per kilogram. Gold's high value and resistance to corrosion have made it people's investment of choice of many millennia.

Lustrous
Delocalised electrons in gold vibrate in response to light and produce light of their own. This gives gold its shiny, lustrous shimmer.

Very high conductivity
Delocalised electrons move easily through the gold lattice, which allows the rapid transfer of heat energy and electrical current.

Non-toxic
While metallic gold is non-toxic, gold (I) and (III) ions (Au^+ and Au^{3+}) are highly toxic when ingested. Despite this, metallic gold has been approved as a safe, tasteless food additive in many countries (sometimes under the name 'E175') because its low reactivity prevents metallic gold from oxidising into gold ions inside the body.

High boiling point
Gold atoms in the metallic lattice are held in place very tightly by very strong electrostatic forces of attraction with the surrounding delocalised 6s electrons. These forces (also called metallic bonds) are stable in solid and liquid gold, and give rise to gold's extremely high boiling point: 2,970°C.

Unreactive: corrosion-resistant
Gold's 6s orbital is relativistically contracted toward the nucleus more than any other element. Its $6s^1$ electron thus has a high probability to be found among the inner electron shells. Only the most reactive substances can tug gold's $6s^1$ electron out from among the others. Hence, gold's resistance to tarnishing and corrosion are consequences of special relativity!

Yellow colour
Gold absorbs blue light when incident photons between 200-300 nm in wavelength cause electrons in the 5d suborbital to move up to the 6s suborbital. While all elements with Z≥39 have a 5d electron subshell, only the energy difference between the 5d and 6s subshells in gold and caesium are equal to the energy of a 'blue' photon. This is due to the relativistic effects unique to each element that alter the exact energy values of higher-energy subshells, in which orbiting electrons approach the speed of light.

Figure 12.208: Chemistry of Gold

12.3.2.9.2 Mass–Energy equivalence

Under the action of a force F, the speed of a mass m increases or decreases on each portion of the trajectory. The work of the component $F\mathrm{d}x$ can then be interpreted into kinetic energy $\mathrm{d}E_c$.

In the relativistic theory, the mass varies with speed as we have just prove it, therefore:

$$E_c = \int F\mathrm{d}x = \int_0^v \frac{\mathrm{d}p}{\mathrm{d}t}\mathrm{d}x = \int_0^v \mathrm{d}p\frac{\mathrm{d}x}{\mathrm{d}t} = \int_0^v \mathrm{d}(mv)v \qquad (12.3.248)$$

The integration by parts (see section Differential and Integral Calculus page 1532):

$$\int a\mathrm{d}b = ab - \int b\mathrm{d}a \qquad (12.3.249)$$

give us:

$$\begin{aligned}
E_c&=mv^2-\int\limits_0^v mv\mathrm{d}v=\frac{m_0v2}{\sqrt{1-\dfrac{v^2}{c^2}}}-\int\limits_0^v\frac{m_0v}{\sqrt{1-\dfrac{v^2}{c^2}}}\mathrm{d}v\\
&\underset{\substack{x=(v/c)^2\\ \mathrm{d}x=2v\mathrm{d}v/c^2}}{=}\frac{m_0v^2}{\sqrt{1-\dfrac{v^2}{c^2}}}-\frac{m_0c^2}{2}\int\limits_0^{(v/c)^2}\frac{1}{\sqrt{1-x}}\mathrm{d}x=\frac{m_0v^2}{\sqrt{1-\dfrac{v^2}{c^2}}}-\frac{m_0c^2}{2}\left[-2\sqrt{1-x}\right]_0^{(v/c)^2}\\
&=\frac{m_0v^2}{\sqrt{1-\dfrac{v^2}{c^2}}}+m_0c^2\left[\sqrt{1-x}\right]_0^{(v/c)^2}=\frac{m_0v^2}{\sqrt{1-\dfrac{v^2}{c^2}}}+m_0c^2\left(\sqrt{1-\frac{v^2}{c^2}}-1\right)\\
&=\frac{m_0v^2}{\sqrt{1-\dfrac{v^2}{c^2}}}+m_0c^2\sqrt{1-\frac{v^2}{c^2}}-m_0c^2=\frac{m_0v^2+m_0c^2\left(1-\dfrac{v^2}{c^2}\right)^2}{\sqrt{1-\dfrac{v^2}{c^2}}}-m_0c^2\\
&=\frac{m_0v^2+m_0c^2-m_0v^2}{\sqrt{1-\dfrac{v^2}{c^2}}}-m_0c^2=\frac{m_0c^2}{\sqrt{1-\dfrac{v^2}{c^2}}}-m_0c^2=mc^2-m_0c^2=\Delta mc^2
\end{aligned}\tag{12.3.250}$$

The gain of kinetic energy of a particle can be considered as gain in its apparent mass. Since m_0 is the rest mass, the quantity m_0c^2 is named "rest energy" of the particle.

We then have:

$$E_c=mc^2-m_0c^2\Leftrightarrow mc^2=E_c+m_0c^2\tag{12.3.251}$$

where E_c represents the energy of motion (kinetic energy).

The sum of:

$$E_c+m_0c^2\tag{12.3.252}$$

therefore represents the total energy E of the particle in the absence of the potential field. Which brings us to write:

$$mc^2=E_c+m_0c^2\tag{12.3.253}$$

hence:

$$\boxed{E=mc^2}\tag{12.3.254}$$

This relation is confirmed in numerous ways, one of the most famous and precise experimental tests at a $\sim5\sigma$ threshold (0.00004%) being [452].

This relation can be interpreted as the fact that mass is an emergent property of the energy (we know nowadays that's the mass is a property acquired by fundamental particles interacting with the Higgs field). Especially, that kinetic energy can be converted into mass and vice versa and this is typically what most particles accelerators do million of times every day.

Remark

Actually nothing seems to indicate in our observable universe, the existence of negative mass. Even anti-particles don't have a negative mass (they have opposite charge but not opposite mass)! So their energy/mass don't cancels. The CERN-SPS (Super Proton Synchrotron) proton-antiproton collider was the first hadron collider operating with bunched beams. Their collision generated plenty of other particles (internal quarks and gluons).

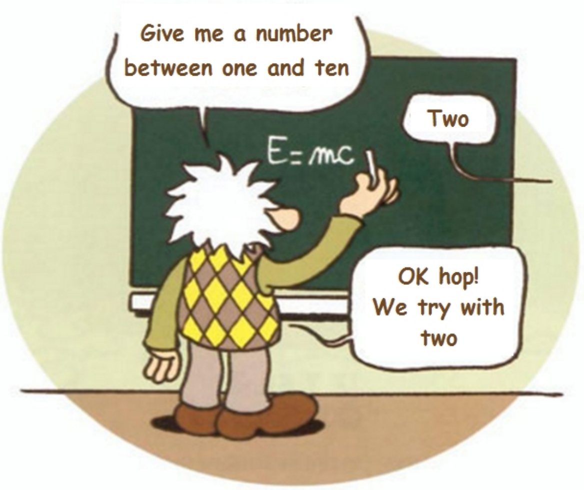
Many physicists like better to write that latter relation as following:

$$\Delta m=\frac{\Delta E}{c^2} \tag{12.3.255}$$

or in natural units (used by most professionals high level physicists):

$$E=m \tag{12.3.256}$$

So what you have to understand with this relation is that when for example (special case example!) you heat up an object in everyday life, you are increasing its mass even if it is not perceptible with a domestic balance!



Give me a number between one and ten
Two
E=mc
OK hop! We try with two

Finally we could also get the same result in another way using Lagrangian mechanics (see section Analytical Mechanics page 3152) as shown below:

12.3.2.9.3 Relativistic Lagrangian

The following developments will help us in the study of Electrodynamics (if this section has not been read yet), to determine the expression of the tensor of the electromagnetic field and in Relativistic Quantum Physics to determine the Klein-Gordon equation with magnetic field. So be sure to carefully read what follows.

In Special Relativity, so we want the equations of motion have the same form in all inertial frames. For this, we need the action S (see section Analytical Mechanics page 3161) to be invariant with respect to Lorentz transformations. Guided by this principle, trying to get the action of a free particle. Suppose that the action is in the reference frame O':

$$S_0=\int L_0\mathrm{d}t'=-mc^2\int \mathrm{d}t' \tag{12.3.257}$$

Remarks

R1. The choice of the minus sign will be evident in our study of electrodynamics.

R2. The notation L_0 instead of the L of Lagrangian lets just emphasize that this is a case study where the system is free. This distinction of notation will be useful in our study of General Relativity and determination of the Tensor of the Electromagnetic field in the section of Electrodynamics.

R3. We are not supposed to know what kind of mass we are dealing with (inertial rest mass), hence the fact that in the ignorance, we will work with the inertial mass m to perhaps correct this hypothesis later if necessary.

And let us recall that:

$$\mathrm{d}t=\frac{\mathrm{d}t'}{\sqrt{1-\dfrac{v^2}{c^2}}}\Leftrightarrow \mathrm{d}t'=\sqrt{1-\frac{v^2}{c^2}}\mathrm{d}t \tag{12.3.258}$$

In the repository O, then we have the "Lorentz invariant action":

$$S=-mc^2\int\sqrt{1-\frac{v^2}{c^2}}\mathrm{d}t \tag{12.3.259}$$

So according to our initial hypothesis, we have for the relativistic Lagrangian (in the absence of potential field... since the system is assumed to be "free"):

$$L_0=-mc^2\sqrt{1-\frac{v^2}{c^2}} \tag{12.3.260}$$

In the non-relativistic approximation $v\ll c$, we have following the Maclaurin development of the square root (see section Sequences and Series page 1703):

$$L_0=-mc^2\sqrt{1-\frac{v^2}{c^2}}\cong -mc^2\left(1-\frac{1}{2}\frac{v^2}{c^2}\right)=-mc^2+\frac{1}{2}mv^2 \tag{12.3.261}$$

We thus fall back on the usual Lagrangian of a free system in movement but more a constant $(-mc^2)$ that does not affect the equations of motion we got in Classical Mechanics but that will be absolutely necessary to us in Electrodynamics.

Let us recall now that the generalized momentum (see section Analytical Mechanics page 3180) is defined by:

$$p_i=\frac{\partial L}{\partial\dot{q}_i} \tag{12.3.262}$$

We will now see that this definition is not accidental. Indeed:

$$p=\frac{\partial L_0}{\partial v}=p\frac{\partial}{\partial v}\left(-mc^2\sqrt{1-\frac{v^2}{c^2}}\right)=-mc^2\left(\sqrt{1-\frac{v^2}{c^2}}\right)=mc^2\frac{v}{c^2\sqrt{1-\frac{v^2}{c^2}}}$$
$$=\frac{mv}{\sqrt{1-\frac{v^2}{c^2}}}\qquad(12.3.263)$$

The Hamiltonian (see section Analytical Mechanics page 3181) is equal to:

$$H(q_i,p_i)=\sum_{i=1}^{n}\dot{q}_ip_i-L(q_i,\dot{q}_i)\qquad(12.3.264)$$

Which gives:

$$H_0=vp-L_0=\frac{mv^2}{\sqrt{1-\frac{v^2}{c^2}}}+mc^2\sqrt{1-\frac{v^2}{c^2}}=\frac{mc^2}{\sqrt{1-\frac{v^2}{c^2}}}\qquad(12.3.265)$$

The Hamiltonian is in this case equal to the total energy of the particle. Its expression led us to change somewhat our initial hypothesis and finally to write m_0 instead of m in the expression of the action S.

So we finally have the Lagrangian of a free relativistic particle:

$$\boxed{L_0=-m_0c^2\sqrt{1-\frac{v^2}{c^2}}}\qquad(12.3.266)$$

and the corresponding Hamiltonian:

$$\boxed{H_0=\frac{m_0c^2}{\sqrt{1-\frac{v^2}{c^2}}}=mc^2}\qquad(12.3.267)$$

In the non-relativistic approximation $v\ll c$, H_0 becomes with a Maclaurin development (see section Sequences and Series page 1703):

$$H_0\cong m_0c^2+\frac{1}{2}m_0v^2\qquad(12.3.268)$$

We recognize the usual kinetic energy, plus a constant: the energy at rest. Which corresponds to the calculations we had made before where we got:

$$mc^2=E_c+m_0c^2=E\Rightarrow E=mc^2\qquad(12.3.269)$$

12.3.2.9.4 Relativistic (linear) momentum

The total energy E and the (linear) momentum $p=mv$ of a particle can therefore take any positive value (when the speed approaches the limit value c, the apparent mass suits for the product $p=mv$ to not be bounded).

In the expression of E, we can replace the speed v^2 by a function p^2:

$$p^2=m^2v^2=\frac{E^2}{c^4}v^2\Rightarrow v^2=\frac{p^2c^4}{E^2} \tag{12.3.270}$$

introduced into:

$$E=mc^2=\frac{m_0c^2}{\sqrt{1-\dfrac{v^2}{c^2}}} \tag{12.3.271}$$

we have:

$$E=\frac{m_0c^2}{\sqrt{1-\dfrac{p^2c^4}{E^2c^2}}}=\frac{m_0c^2}{\sqrt{E^2-p^2c^2}}E \tag{12.3.272}$$

Therefore:

$$\sqrt{E^2-p^2c^2}=m_0c^2\Rightarrow E^2-p^2c^2=m_0^2c^4 \tag{12.3.273}$$

hence (we will come back on that relation of the utmost importance during our proof of Einstein relation):

$$\boxed{E=c\sqrt{m_0^2c^2+p^2}} \tag{12.3.274}$$

We have not kept the negative part of the previous relation as it has no meaning in classical physics. However, when we will study Relativistic Quantum Physics, it will be essential to preserve it otherwise we will get absurdities.

However, we can obviously write this last relation also in the following form named "relativistic mass momentum relation":

$$\boxed{E^2=m_0^2c^4+p^2c^2} \tag{12.3.275}$$

or also (ugly!):

$$E^2=(E(m_0))^2+(E(c))^2 \tag{12.3.276}$$

In other words, the total energy of a moving particle is equal to its mass energy added to its kinetic energy (basically nothing new).

The relation above has two limit cases where we can simplify it:

1. For a particle at rest ($p=0$), we can reduce the expression to:

   $$E=m_0c^2 \tag{12.3.277}$$

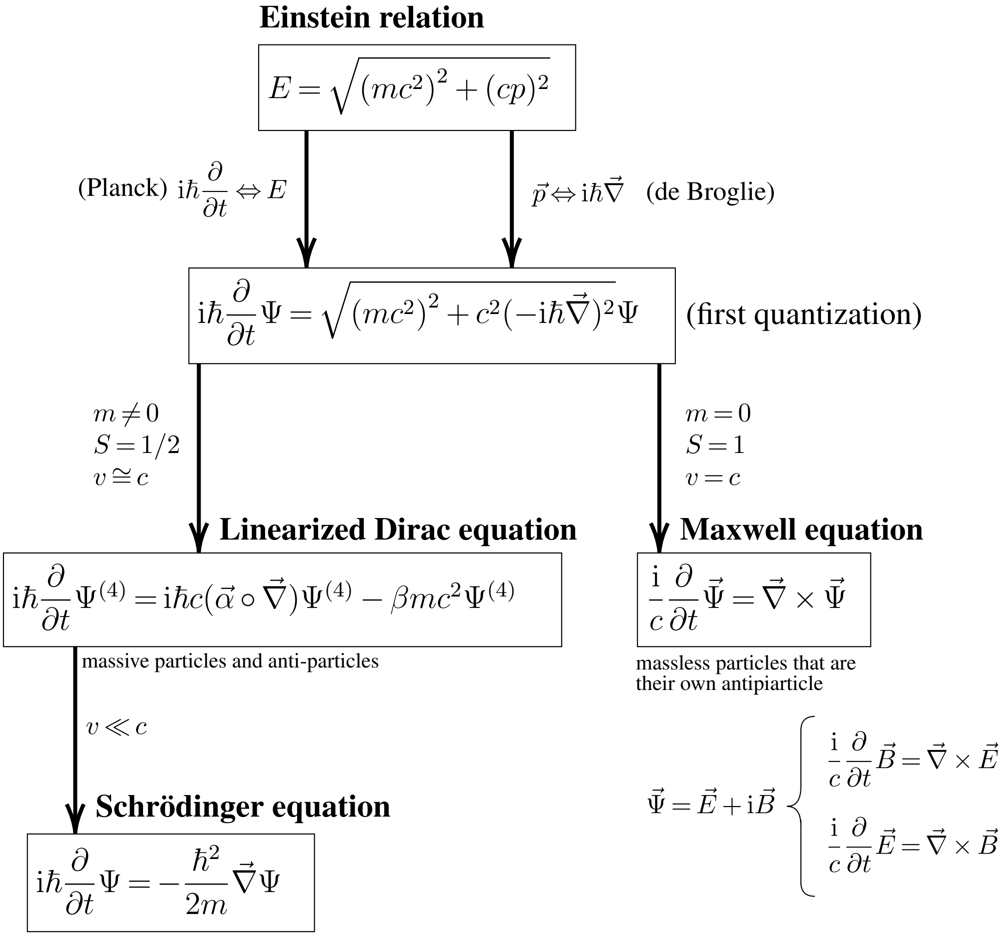
   by omitting the negative energy ... at least for now (sadly the above relation is sometimes denoted $E=mc^2$ by omitting the 0 subscript).

2. We can apply the equation to a particle without mass to eliminate the first term, which then gives us:

$$\boxed{E=pc} \tag{12.3.278}$$

A photon, for example, has a zero rest mass but it is never at rest ...by definition, it is a quantum of energy, kinetic energy is never zero and so it has a mass corresponding to its kinetic energy. Thus, a massless particle at rest moves at the speed of light, regardless of the chosen repository frame! Conversely, a particle with a non-zero rest mass can never reach the speed of light in any repository.

Notice that the relativistic mass moment relation we have proved just earlier above is the first step that has lead us to the Dirac and Schrödinger equation as illustrated below:



Einstein relation
$E=\sqrt{(mc^2)^2+(cp)^2}$
(Planck) $\mathrm{i}\hbar\frac{\partial}{\partial t}\Leftrightarrow E$
$\vec{p}\Leftrightarrow \mathrm{i}\hbar\vec{\nabla}$ (de Broglie)
$\mathrm{i}\hbar\frac{\partial}{\partial t}\Psi=\sqrt{(mc^2)^2+c^2(-\mathrm{i}\hbar\vec{\nabla})^2}\Psi$
(first quantization)
$m\neq 0$
$S=1/2$
$v\cong c$
$m=0$
$S=1$
$v=c$
Linearized Dirac equation
$\mathrm{i}\hbar\frac{\partial}{\partial t}\Psi^{(4)}=\mathrm{i}\hbar c(\vec{\alpha}\circ\vec{\nabla})\Psi^{(4)}-\beta mc^2\Psi^{(4)}$
massive particles and anti-particles
Maxwell equation
$\frac{\mathrm{i}}{c}\frac{\partial}{\partial t}\vec{\Psi}=\vec{\nabla}\times\vec{\Psi}$
massless particles that are their own antipiarticle
$v\ll c$
Schrödinger equation
$\mathrm{i}\hbar\frac{\partial}{\partial t}\Psi=-\frac{\hbar^2}{2m}\vec{\nabla}\Psi$
$\vec{\Psi}=\vec{E}+\mathrm{i}\vec{B}$
$\frac{\mathrm{i}}{c}\frac{\partial}{\partial t}\vec{B}=\vec{\nabla}\times\vec{E}$
$\frac{\mathrm{i}}{c}\frac{\partial}{\partial t}\vec{E}=\vec{\nabla}\times\vec{B}$

Figure 12.209: Relationships between most famous quantum physics equations

Remarks

R1. As we prove it further below (see the "Einstein relation"), from the construction of Planck's law (see section Thermodynamics page 3719), we can write $E=pc=h\nu$.

R2. The mass of the photon can hardly be non-zero! Indeed, quantum theory would be false otherwise. But it has never fail until now (see section Wave Quantum Physics page

4688). We would also have a small change on the Electrostatic force following that it is given by the Yukawa potential (see section Quantum Field Theory page 5164) and this would have been observed in laboratory since...

R3. The reason why some particles have masses and other not is related to Quantum Field Theory (QFT) and especially to something named the "Higgs mechanism" related to a quantum field named the "Higgs field". However why the Higgs field give masses to some particles are not to others is still an opened question in the early 121st century.

Let us now look after the relations between p and p' and between E and E', to make it possible for O' to write:

$$E'=c\sqrt{m_0^2c^4+p'^2} \tag{12.3.279}$$

We then begin to get rid of the square root:

$$E=c\sqrt{m_0^2c^4+p^2}\Rightarrow p^2-\frac{E^2}{c^2}=-m_0^2c^2 \tag{12.3.280}$$

If O write:

$$p_x^2+p_y^2+p_z^2-\frac{E^2}{c^2}=-m_0^2c^4 \tag{12.3.281}$$

O' must be able to write:

$$p'^2_{x'}+p'^2_{y'}+p'^2_{z'}-\frac{E'^2}{c^2}=-m_0^2c^4 \tag{12.3.282}$$

Therefore we have:

$$p_x^2+p_y^2+p_z^2-\frac{E^2}{c^2}=p'^2_{x'}+p'^2_{y'}+p'^2_{z'}-\frac{E'^2}{c^2} \tag{12.3.283}$$

If we identify:

$$x\equiv p_x \qquad y\equiv p_z \qquad z\equiv p_z \qquad ct\equiv\frac{E}{c} \tag{12.3.284}$$

we obtain similar expressions to those used for the Lorentz transformations of spatial and temporal components. We can then write, by similarity, that the changes to the (linear) momentum and energy are therefore given by:

$$\begin{aligned}
p'_{x'}&=\frac{p_x-v\dfrac{E}{c^2}}{\sqrt{1-\dfrac{v^2}{c^2}}}\Leftrightarrow p_x=\frac{p'_{x'}+v\dfrac{E'}{c^2}}{\sqrt{1-\dfrac{v^2}{c^2}}}\\
p'_{y'}&=p_y\Leftrightarrow p_y=p'_{y'}\\
p'_{z'}&=p_z\Leftrightarrow p_z=p'_{z'}\\
E'&=\frac{E-vp_x}{\sqrt{1-\dfrac{v^2}{c^2}}}\Leftrightarrow E=\frac{E'+vp'_x}{\sqrt{1-\dfrac{v^2}{c^2}}}
\end{aligned} \tag{12.3.285}$$

Again, if we take:

$$\gamma=\frac{1}{\sqrt{1-\dfrac{v^2}{c^2}}}=\frac{1}{1-\beta^2} \tag{12.3.286}$$

We therefore have by expressing all previous relations of transformation in the same units by remembering that $E\equiv pc$ (for a photon!):

$$\begin{aligned} p_x c &= \gamma({p'}_{x'}c+\beta E') \\ p_y c &= {p'}_{y'}c \\ p_z c &= {p'}_{z'}c \\ E &= \gamma(E'+\beta c{p'}_x) \end{aligned} \tag{12.3.287}$$

We can the define a matrix such that:

$$\begin{pmatrix} E \\ p_x c \\ p_y c \\ p_z c \end{pmatrix}=\begin{bmatrix} \gamma & \gamma\beta & 0 & 0 \\ \gamma\beta & \gamma & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix}\begin{pmatrix} E' \\ {p'}_{x'}c \\ {p'}_{y'}c \\ {p'}_{z'}c \end{pmatrix} \tag{12.3.288}$$

where we fall back on the "Lorentz matrix" or "symmetric Lorentz tensor" ${L'}_{\mu}^{\nu}$

The vector:

$$\boxed{p^{\nu}=\left(\frac{E}{c},p_x,p_y,p_z\right)=\left(\frac{E}{c},\vec{p}\right)=m\gamma(\vec{v})(c,\vec{v})} \tag{12.3.289}$$

is meanwhile, named the "four-vector energy-momentum" or just "four-momentum" Its utility is that its value is also conserved and this is especially useful for the study of nuclear reactions. If we add these vectors on all particles (without forgetting the photons as well!!!) before and after the reaction, we should found the same quantities for the 4 components!

Remarks

R1. The inverse transformation being done obviously with the inverse matrix that we have already outlined earlier above.

R2. We use in Relativistic Optics the four-vector $(\omega/c,\vec{k})$, where ω is for recall the pulsation of the wave and $\vec{k}$ the wave vector (see sections Wave Mechanics and Wave Optics page 3480). This four-vector is the equivalent for an electromagnetic wave of the four-vector $(E/c,\vec{p})$ for a particle multiplied by the reduced Planck's constant $\hbar=h/2\pi$. Indeed, the wave-particle duality (see section Wave Quantum Physics page 4688) attributes to a wave an energy according to the Planck-Einstein relation (see section Corpuscular Quantum Physics page 4627):

$$E=h\nu=\frac{h}{2\pi}\omega=\hbar\omega \tag{12.3.290}$$

and a linear momentum which norm is:

$$p=\frac{E}{c}=\hbar\frac{\omega}{c}=\hbar k \qquad (12.3.291)$$

Now let us come back to the following relation that is of main importance in some areas of quantum physics:

$$p_x^2+p_y^2+p_z^2-\frac{E^2}{c^2}=-m_0^2c^4 \qquad (12.3.292)$$

Therefore:

$$\frac{E^2}{c^2}-(p_x^2+p_y^2+p_z^2)=m_0^2c^4 \qquad (12.3.293)$$

Which can be written in vector form (very common form):

$$\frac{E^2}{c^2}-\|\vec{p}\|=m_0^2c^4 \qquad (12.3.294)$$

This latter relation will be very useful in the section of Relativistic Quantum Physics to calculate the energy of virtual photons exchange.

For photons, since the mass is zero, we have:

$$\frac{E^2}{c^2}-\|\vec{p}\|=0 \qquad (12.3.295)$$

Finally let us also notice that the four-momentum is also related to a another quantity named "four-wave vector" as following:

$$\boxed{p^\nu=\left(\frac{E}{c},\vec{p}\right)=\hbar k^\nu=\hbar\left(\frac{\omega}{c},\vec{k}\right)} \qquad (12.3.296)$$

as we know that (for the first component):

$$E=h\nu=\hbar\omega \qquad (12.3.297)$$

and that for all other components :

$$p=mc=\frac{E}{c}=\frac{h\nu}{c}=\frac{\hbar\omega}{c}=\frac{\hbar kc}{c}=\hbar k \qquad (12.3.298)$$

12.3.2.9.4.1 Einstein relation

Following the principle of relativity, we wish that the relation between the linear momentum and energy of an electromagnetic wave can be written in the same way for two inertial observers in translation relative to the other!

If O writes:

$$E=c\sqrt{m_0^2c^4+p^2} \qquad (12.3.299)$$

then O' must be able to write:

$$E' = c\sqrt{m_0^2c^4 + p'^2} \tag{12.3.300}$$

Let us take the first relation above and put it to the square without forgetting that the photon has a zero rest mass m_0. Therefore:

$$\boxed{E^2 = m_0^2c^4 + p^2c^2} \tag{12.3.301}$$

and as $m_0 = 0$ for the photon:

$$E = pc \tag{12.3.302}$$

Given the known Planck's law (see section Thermodynamics page 3719):

$$E = h\nu \tag{12.3.303}$$

we are led to write the famous "Einstein's relation" that we will find very often in Quantum Physics and in Thermodynamics:

$$\boxed{p = \frac{h\nu}{c}} \tag{12.3.304}$$

So even if the photon has no mass at rest, it has a "relativistic mass". This relativistic mass is in Special Relativity for the photon the equivalent to the electric charge in Electrodynamics.

Remark

Notice that a priori nothing seems to prevent us to write $E = h\nu = mc^2$. Therefore it means that without mass there is no frequency. By extrapolation in a Universe without mass (made only of radiation) there is no clock and therefore no time and hence no distance. In the late 120th century (holocene calendar) this is speculative and need to be verified experimentally if it's possible...

12.3.2.9.4.2 Time of flight

Suppose we get a beam made of massive particles. The rest mass is m_0. The particle travels a distance L in its inertial frame. The particle has an energy E in that frame. Therefore, the so-called "time of flight" from two points at $x = 0$ and $x = L$ will be:

$$T = \frac{L}{v} = \frac{m_0\gamma L}{m_0\gamma v} = \frac{m_0\gamma L}{p} = \frac{m\gamma c^2 L}{pc^2} \tag{12.3.305}$$

where we use the relativistic definition of momentum:

$$p = m_0\gamma v \tag{12.3.306}$$

Now, knowing that the relativistic energy is:

$$E = m_0\gamma c^2 \tag{12.3.307}$$

using the time that a mass-less light beam uses to travel the proper distance L, easily calculated to be:

$$\tau=\frac{L}{c} \tag{12.3.308}$$

we get:

$$T=\frac{EL}{pc^2}=\frac{E\tau}{pc}=\frac{\tau}{pc/E} \tag{12.3.309}$$

But we have just proved that:

$$p^2c^2=E^2-m_0^2c^4 \tag{12.3.310}$$

Therefore:

$$\frac{p^2c^2}{E^2}=1-\frac{m_0c^4}{E^2} \tag{12.3.311}$$

and then:

$$\frac{pc}{E}=\sqrt{1-\left(\frac{m_0c^2}{E}\right)^2} \tag{12.3.312}$$

Thus, the time of flight is finally written as follows:

$$\boxed{T=\frac{\tau}{\sqrt{1-\left(\dfrac{m_0c^2}{E}\right)^2}}} \tag{12.3.313}$$

This equation is very important in practical applications. Specially in Astrophysics and baseline beam experiments, like those involving the neutrinos! Indeed, we usually calculate the difference between the photon (or any other massless) time of arrival and that of massive particles, e.g. the neutrinos. Several neutrino experiments can measure this difference using a well designed experimental set-up. The difference between those times of flight (the neutrino time of flight minus the photon time of flight) is:

$$T-\tau=\frac{\tau}{\sqrt{1-\left(\dfrac{m_0c^2}{E}\right)^2}}-\tau \tag{12.3.314}$$

or equivalently:

$$\Delta t=T-\tau=\tau\left(\frac{\tau}{\sqrt{1-\left(\dfrac{m_0c^2}{E}\right)^2}}-1\right) \tag{12.3.315}$$

or as well:

$$Q=\frac{\Delta t}{\tau}=\left(\frac{\tau}{\sqrt{1-\left(\dfrac{m_0c^2}{E}\right)^2}}-1\right) \tag{12.3.316}$$

This last expression can also be expressed in terms of the speed of light and neutrinos, since:

$$c=\frac{L}{\tau} \qquad \text{and} \qquad v_\nu=\frac{L}{T} \tag{12.3.317}$$

so:

$$\frac{T-\tau}{\tau}=\frac{T/L-\tau/L}{\tau/L}=\frac{1/v_\nu-1/c}{1/c}=\frac{c-v_\nu}{v_\nu} \tag{12.3.318}$$

Therefore:

$$\boxed{Q=\frac{\Delta t}{\tau}=\frac{c-v_\nu}{v_\nu}} \tag{12.3.319}$$

In the special case of very non-heavy left-handed neutrinos, the rest mass is tiny (likely sub-[eV] and next to the [meV] scale), and then we can make a Taylor expansion for Q if:

$$x=\frac{mc}{E}\ll 1 \tag{12.3.320}$$

Then:

$$Q=\frac{\Delta t}{\tau}=\left(\frac{\tau}{\sqrt{1-\left(\dfrac{m_0c^2}{E}\right)^2}}-1\right)\cong\left(1+\frac{1}{2}\left(\frac{m_0c^2}{E}\right)^2\right)-1=\frac{1}{2}\left(\frac{m_0c^2}{E}\right)^2 \tag{12.3.321}$$

Then, we would expect, accordingly to Special Relativity, of course, that:

$$\frac{c-v_\nu}{v_\nu}=\frac{T-\tau}{\tau}\cong\frac{1}{2}\left(\frac{m_0c^2}{E}\right)^2 \tag{12.3.322}$$

We can guess how large it is plugging "typical" values for the neutrino mass and energy. For instance, taking $m_\nu\cong 1$ [meV] and $E\cong 1$ [GeV] the Q value is about 10^{-24}.

Nowadays, we have no clock with this precision, so the neutrino mass measurement using this approach is impossible with current technology. However, it is clear that if we could make clocks with that precision, we would measure the neutrino mass with this "time of flight" procedure. It is a challenge. We can not do that in these times (circa 12012 according to holocene calendar), and thus we don't measure any time delay in baseline experiments. Then, neutrinos move with $v_\nu=c$ and since there is no observed delay (beyond the OPERA result, already corrected), neutrinos are, thus, ultra-relativistic particles, and for them $E=pc$ with great accuracy.

12.3.2.9.4.3 Relativistic force

Following the principle of relativity, we want that the relation between force and linear momentum to be written in the same way by two inertial observers in translation relative to each other!

Therefore if O writes:

$$\vec{F}=\frac{\mathrm{d}\vec{p}}{\mathrm{d}t} \tag{12.3.323}$$

O' must be able to write:

$$\vec{F}\,' = \frac{\mathrm{d}\vec{p}\,'}{\mathrm{d}t'} \tag{12.3.324}$$

The relation between $\vec{F}$ and $\vec{F}\,'$ is quite complicated in the general case. We will limit ourselves here to the particular case where a body is momentarily at rest in O' and therefore where the observer O' will only take into account the force $\vec{F}\,'$ that he applies. He will name this the "proper force" because it has not to worry about other forces (such as centrifugal (fictional) force, for example).

It is necessary to substitute p' and t' by p and t in:

$$F'_x = \frac{\mathrm{d}p'_x}{\mathrm{d}t'} \qquad F'_y = \frac{\mathrm{d}p'_y}{\mathrm{d}t'} \qquad F'_z = \frac{\mathrm{d}p'_z}{\mathrm{d}t'} \tag{12.3.325}$$

Since:

$$\frac{\mathrm{d}t}{\mathrm{d}t'} = \frac{1}{1-\dfrac{v^2}{c^2}} \tag{12.3.326}$$

we will have:

$$\begin{aligned}F'_x &= \frac{\mathrm{d}p'_x}{\mathrm{d}t'} = \frac{\mathrm{d}p'_x}{\mathrm{d}t} = \frac{\mathrm{d}t}{\mathrm{d}t'}\frac{\mathrm{d}}{\mathrm{d}t}\left(\frac{p_x - v\dfrac{E}{c^2}}{\sqrt{1-\dfrac{v^2}{c^2}}}\right) = \frac{\mathrm{d}t}{\mathrm{d}t'}\frac{\mathrm{d}}{\mathrm{d}t}\left(\frac{1}{\sqrt{1-\dfrac{v^2}{c^2}}}\left(p_x - v\frac{E}{c^2}\right)\right)\\ &= \frac{\mathrm{d}t}{\mathrm{d}t'}\left(\frac{1}{\sqrt{1-\dfrac{v^2}{c^2}}}\right)\frac{\mathrm{d}}{\mathrm{d}t}\left(p_x - v\frac{E}{c^2}\right) = \left(\frac{1}{\sqrt{1-\dfrac{v^2}{c^2}}}\right)\left(\frac{1}{\sqrt{1-\dfrac{v^2}{c^2}}}\right)\frac{\mathrm{d}}{\mathrm{d}t}\left(p_x - v\frac{E}{c^2}\right)\\ &= \frac{1}{\sqrt{1-\dfrac{v^2}{c^2}}}\frac{\mathrm{d}}{\mathrm{d}t}\left(p_x - v\frac{E}{c^2}\right) = \frac{1}{\sqrt{1-\dfrac{v^2}{c^2}}}\left(\frac{\mathrm{d}p_x}{\mathrm{d}t} - \frac{v}{c^2}\frac{\mathrm{d}E}{\mathrm{d}t}\right)\end{aligned} \tag{12.3.327}$$

We have seen also previously that:

$$E = E_c + m_0c^2 \Rightarrow \frac{\mathrm{d}E}{\mathrm{d}t} = \frac{\mathrm{d}E_c}{\mathrm{d}t} + 0 = \frac{F_x\mathrm{d}x}{\mathrm{d}t} = F_xv \tag{12.3.328}$$

Therefore it remains:

$$F'_x = \frac{1}{1-\dfrac{v^2}{c^2}}\left(F_x - \frac{v}{c^2}F_xv\right) = F_x \tag{12.3.329}$$

The component of the force is therefore invariant in the direction of the movement.

For the directions y and z perpendicular to the movement:

$$F'_y = \frac{\mathrm{d}p'_y}{\mathrm{d}t'} = \frac{\mathrm{d}t}{\mathrm{d}t'}\frac{\mathrm{d}p_y}{\mathrm{d}t} = \frac{F_y}{\sqrt{1-\dfrac{v^2}{c^2}}} \qquad \text{and} \qquad F'_z = \frac{\mathrm{d}p'_z}{\mathrm{d}t'} = \frac{\mathrm{d}t}{\mathrm{d}t'}\frac{\mathrm{d}p_z}{\mathrm{d}t} = \frac{F_z}{\sqrt{1-\dfrac{v^2}{c^2}}} \tag{12.3.330}$$

So for summary:

$$\boxed{\begin{gathered}F'_x = F_x \Leftrightarrow F_x = F'_x \\ F'_y = \frac{F_y}{\sqrt{1-\dfrac{v^2}{c^2}}} \Leftrightarrow F_y = F'_y\sqrt{1-\frac{v^2}{c^2}} \\ F'_z = \frac{F_z}{\sqrt{1-\dfrac{v^2}{c^2}}} \Leftrightarrow F_z = F'_z\sqrt{1-\frac{v^2}{c^2}}\end{gathered}} \tag{12.3.331}$$

However, to change from one reference frame to another, it is better to use again the "four-vector force" defined as the derivative of the four momentum vector with respect to the proper time:

$$\boxed{F^\nu = \frac{\mathrm{p}^\nu}{\mathrm{d}t'} = \frac{\mathrm{d}t}{\mathrm{d}t'}\frac{\mathrm{d}p^\nu}{\mathrm{d}t} = \gamma\frac{\mathrm{d}p^\nu}{\mathrm{d}t} = \gamma\frac{\mathrm{d}}{\mathrm{d}t}\left(\frac{E}{c},\vec{p}\right) = \gamma\left(\frac{\vec{F}\circ\vec{v}}{c},\vec{F}\right)} \tag{12.3.332}$$

Indeed, let us recall that:

$$\frac{\mathrm{d}E}{\mathrm{d}t} = \vec{F}\circ\vec{v} \qquad \vec{F} = \frac{\mathrm{d}\vec{p}}{\mathrm{d}t} \tag{12.3.333}$$

12.3.2.10 Relativistic electrodynamics

With a mass spectrometer we establish that the ratio m/q of the mass m of a particle by its electrical charge q varies in the same way as the mass m when the velocity v of the particle varies:

$$\boxed{\frac{m}{q}=\frac{m_0/q_0}{\sqrt{1-\dfrac{v^2}{c^2}}}=\frac{1}{q_0}\frac{m_0}{\sqrt{1-\dfrac{v^2}{c^2}}}=\frac{m}{q_0}} \tag{12.3.334}$$

Thus, it comes that:

$$q=q_0 \tag{12.3.335}$$

The charge of a particle is therefore independent of its velocity, as we have proved in the section of Electromagnetism (see section Electrodynamics page 4114) when determining the charge conservation equation.

Let us consider now two charges q and Q immobile a reference frame O' in translation at speed v with respect to another one centered on O:

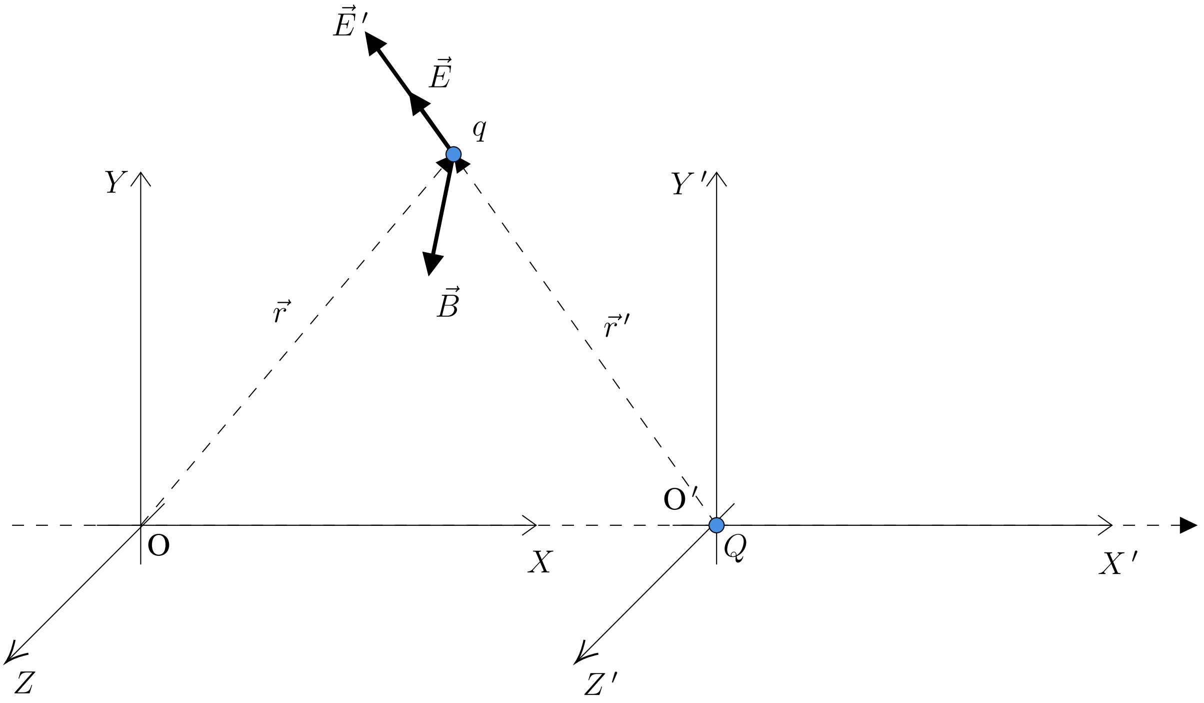


Figure 12.210: **Configuration for the study of transformations of electric and magnetic fields**

We will restrict ourselves to the case where the velocity $\vec{v}$ is parallel to the Ox-axis:

$$\vec{v}=(v_x,0,0) \tag{12.3.336}$$

and we write the vector at the horizontal to spare time and paper...

The electric charge Q is place on O' and is therefore fixed for O'. The observer O' makes the conclusions that an electrostatic force:

$$\vec{F}'=q\vec{E}' \tag{12.3.337}$$

act on the reference particle q placed on $\vec{r}'$:

$$F'_x = qE'_x \qquad F'_y = qE'_y \qquad F'_z = qE'_z \tag{12.3.338}$$

The observer O also sees an electrostatic field $\vec{E}$ in $\vec{r}$, but he also sees that Q is in movement along the Ox-axis. He thus deduces the existence of a magnetic field $\vec{B}$ on $\vec{r}$ oriented in the plane YZ plane:

$$\vec{B} = (0, B_y, B_z) \tag{12.3.339}$$

It therefore measures the supposedly known Lorentz's force (see section Magnetostatics page 4052):

$$\vec{F} = q(\vec{E} + \vec{v} \times \vec{B}) \tag{12.3.340}$$

But:

$$\vec{v} \times \vec{B} = \begin{pmatrix} v_x \\ 0 \\ 0 \end{pmatrix} \times \begin{pmatrix} 0 \\ B_y \\ B_z \end{pmatrix} = \begin{pmatrix} 0-0 \\ 0 - v_x B_z \\ v_x B_y \end{pmatrix} = \begin{pmatrix} 0 \\ -vB_z \\ vB_y \end{pmatrix} \tag{12.3.341}$$

Therefore:

$$F_x = qE_x \qquad F_y = q(E_y - vB_z) \qquad F_z = q(E_z + vB_y) \tag{12.3.342}$$

We have now seen:

$$\begin{aligned} F'_x &= F_x = qE_x \\ F'_y &= \frac{F_y}{\sqrt{1-\dfrac{v^2}{c^2}}} = \frac{q(E_y - vB_z)}{\sqrt{1-\dfrac{v^2}{c^2}}} \\ F'_z &= \frac{F_z}{\sqrt{1-\dfrac{v^2}{c^2}}} = \frac{q(E_z + vB_y)}{\sqrt{1-\dfrac{v^2}{c^2}}} \end{aligned} \tag{12.3.343}$$

The comparison of the expressions above gives the relativistic transformations of the electric field:

$$\boxed{\begin{gathered} E'_x = E_x \Leftrightarrow E_x = E'_x \\ E'_y = \frac{E_y - vB_z}{\sqrt{1-\dfrac{v^2}{c^2}}} \Leftrightarrow E_y = \frac{E'_y + vB'_z}{\sqrt{1-\dfrac{v^2}{c^2}}} \\ E'_z = \frac{E_z + vB_y}{\sqrt{1-\dfrac{v^2}{c^2}}} \Leftrightarrow E_z = \frac{E'_z - vB'_y}{\sqrt{1-\dfrac{v^2}{c^2}}} \end{gathered}} \tag{12.3.344}$$

As for the Lorentz transformation of the spatial and temporal components, we have obtained the inverse transformations by exchanging the fields and considering that O' sees O going back away (we therefore replace v by $-v$).

The above relations, sometimes named "Joules-Bernoulli equations of the electric field", make it clear that if, for example, the electric field in one of the reference systems is zero but the magnetic field is not, then an electric field exists from the point of view of the other reference frame !!! It is therefore an absolute victory of relativity in comparison to classical mechanics!

To get the relativistic transformations of the magnetic field, we proceed as follows:

$$E'_y=\frac{E_y-vB_z}{\sqrt{1-\dfrac{v^2}{c^2}}}=\frac{\dfrac{E'_y+vB'_z}{\sqrt{1-\dfrac{v^2}{c^2}}}-vB_z}{\sqrt{1-\dfrac{v^2}{c^2}}} \tag{12.3.345}$$

After some small manipulations of very elementary algebra, we get:

$$B_z=\frac{B'_z+\dfrac{v}{c^2}E'_y}{\sqrt{1-\dfrac{v^2}{c^2}}} \tag{12.3.346}$$

And identically:

$$E_y=\frac{E'_y-vB'_z}{\sqrt{1-\dfrac{v^2}{c^2}}}=\frac{\dfrac{E_y-vB_z}{\sqrt{1-\dfrac{v^2}{c^2}}}+vB_z}{\sqrt{1-\dfrac{v^2}{c^2}}} \tag{12.3.347}$$

After a few simple manipulations of very elementary algebra, we get:

$$B'_z=\frac{B_z-\dfrac{v}{c^2}E_y}{\sqrt{1-\dfrac{v^2}{c^2}}} \tag{12.3.348}$$

And so on. Finally, we get:

$$\boxed{\begin{gathered}B'_x=B_x\Leftrightarrow B_x=B'_x\\ B'_y=\frac{B_y+\dfrac{v}{c^2}E_z}{\sqrt{1-\dfrac{v^2}{c^2}}}\Leftrightarrow B_y=\frac{B'_y-\dfrac{v}{c^2}E'_z}{\sqrt{1-\dfrac{v^2}{c^2}}}\\ B'_z=\frac{B_z-\dfrac{v}{c^2}E_y}{\sqrt{1-\dfrac{v^2}{c^2}}}\Leftrightarrow B_z=\frac{B'_z+\dfrac{v}{c^2}E'_y}{\sqrt{1-\dfrac{v^2}{c^2}}}\end{gathered}} \tag{12.3.349}$$

The above relations, sometimes named "Joules-Bernoulli equations of the magnetic field", make it clear that if, for example, the magnetic field in one of the reference frame is zero but the electric field is not, then a magnetic field exists from the point of view of the other reference fame !!! It is therefore once again an absolute victory of relativity in comparison to classical mechanics!

Let us now study the behaviour of the electromagnetic field of a moving charge:

Let us consider two parallel referentials O and O', in translation at constant velocity v along the axis XX':

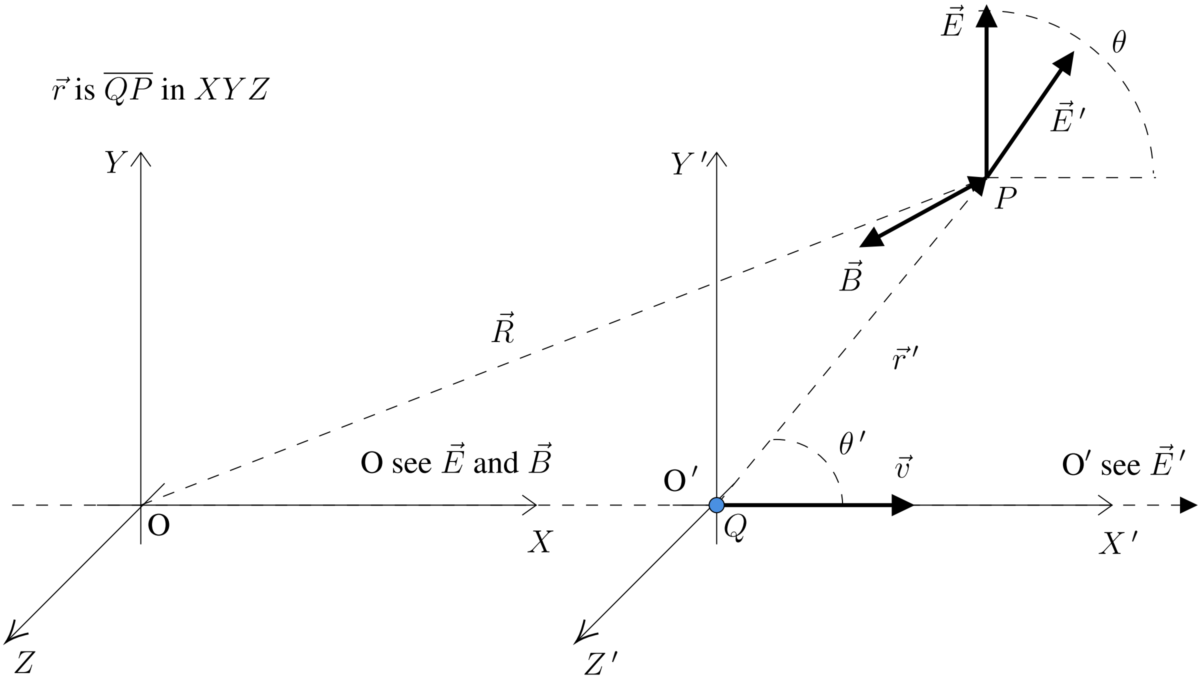

Figure 12.211: **Configuration for the study of electrodynamic transformations**

where a fixed electric charge Q is placed at O'.

It is clear that the observer O measures $\vec{B}=\vec{0}$ everywhere and that at the point P of the plane $X'Y'$, on $\vec{r}\,'=(x',y',0)$ he measures the electrostatic field (see section Electrostatics page 3968):

$$\vec{E}\,'=\begin{pmatrix}E'_x\\E'_y\\0\end{pmatrix}=\frac{Q}{4\pi\varepsilon_0 r'^3}\vec{r}\,'=\frac{Q}{4\pi\varepsilon_0}r'^3\begin{pmatrix}x'\\y'\\0\end{pmatrix}\qquad(12.3.350)$$

If the observer O is informed of the values of $\vec{E}\,'$ and of $\vec{B}\,'=\vec{0}$, he can introduce them into the relativistic transformation giving the electric field $\vec{E}$ that he observes:

$$E_x=E'_x\qquad(12.3.351)$$

$$E_y=\frac{E'_y+vB'_z}{\sqrt{1-\dfrac{v^2}{c^2}}}=\frac{E'_y}{\sqrt{1-\dfrac{v^2}{c^2}}}\qquad(12.3.352)$$

$$E_z=\frac{E'_z-vB'_y}{\sqrt{1-\dfrac{v^2}{c^2}}}=\frac{E'_z}{\sqrt{1-\dfrac{v^2}{c^2}}}\qquad(12.3.353)$$

To write an expression of the field $\vec{E}$ at the point P, the observer O must determine, at a time t of its local time, the components of the vector $\vec{r}=(x,y,0)$ which separates the point P from the electric charge Q (by summing the position vectors of the latter two material points).

The coordinates of the point P and of the charge Q that he sees in the plane XYZ are given by the usual Lorentz transformations:

$$\vec{R}_P=\left(\frac{x'+vt}{\sqrt{1-\frac{v^2}{c^2}},y',0}\right) \qquad \text{and} \qquad \vec{R}_Q=\left(\frac{vt}{\sqrt{1-\frac{v^2}{c^2}},0,0}\right) \tag{12.3.354}$$

He thus easily deduces, by summation, the distances x, y.

Another simpler possible method is that since the x component is a length, it therefore undergoes Lorentz transformations and:

$$\vec{r}=(x,y,z)=\left(x'\sqrt{1-\frac{v^2}{c^2}},y',0\right) \tag{12.3.355}$$

Since for recall:

$$x'=\frac{x}{\sqrt{1-\frac{v^2}{c^2}}} \qquad \text{and} \qquad y'=y \tag{12.3.356}$$

The relativistic transformation of the electric field then gives:

$$E_x=E'_x=\frac{Q}{4\pi\varepsilon_0 r'^3}x'=\frac{Q}{4\pi\varepsilon_0 r'^3}\frac{x}{\sqrt{1-\frac{v^2}{c^2}}} \tag{12.3.357}$$

$$E_y=\frac{E'_y}{\sqrt{1-\frac{v^2}{c^2}}}=\frac{1}{\sqrt{1-\frac{v^2}{c^2}}}\frac{Q}{4\pi\varepsilon_0 r'^3}y'=\frac{Q}{4\pi\varepsilon_0 r'^3}\frac{y}{\sqrt{1-\frac{v^2}{c^2}}} \tag{12.3.358}$$

and:

$$E_z=E'_z=0 \tag{12.3.359}$$

Written in vector form:

$$\vec{E}=\frac{Q\vec{r}}{4\pi\varepsilon_0\sqrt{1-\frac{v^2}{c^2}}}\frac{1}{r'^3} \tag{12.3.360}$$

We must also determine how to express r' as a function of r:

$$r'2=x'^2+y'^2=\frac{x^2}{1-\frac{v^2}{c^2}}+y^2=\frac{x^2+\left(1-\frac{v^2}{c^2}\right)y^2}{1-\frac{v^2}{c^2}}=\frac{r^2-\frac{v^2}{c^2}y^2}{1-\frac{v^2}{c^2}} \tag{12.3.361}$$

as (Pythagorean theorem):

$$x^2+y^2=r^2 \tag{12.3.362}$$

The writing is simplified if we use the angle formed by the electric field vector and the x-axis. We then denote then θ' in O' and the θ in O the angles given by:

$$\tan(\theta')=\frac{y'}{x'} \qquad \text{and} \qquad \tan(\theta)=\frac{y}{x} \tag{12.3.363}$$

with $\theta\geq\theta'$ due to the expansion of the lengths along the x-axis.

We eliminate y with:

$$y^2=r^2\sin^2(\theta)\Rightarrow r'=\frac{r\left[1-\dfrac{v^2}{c^2}\sin^2(\theta)\right]^{1/2}}{\sqrt{1-\dfrac{v^2}{c^2}}} \tag{12.3.364}$$

Thus, the electric field $\vec{E}$ that sees O is given by:

$$\boxed{\vec{E}=\frac{Q\vec{r}}{4\pi\varepsilon_0\sqrt{1-\dfrac{v^2}{c^2}}}\frac{1}{r'^3}=\frac{1-\dfrac{v^2}{c^2}}{\left[1-\dfrac{v^2}{c^2}\sin^2(\theta)\right]^{3/2}}\frac{Q\vec{r}}{4\pi\varepsilon_0 r^3}} \tag{12.3.365}$$

The factor containing $\sin(\theta)$ shows that the electric field $\vec{E}$ of a moving charge no longer has a spherical symmetry!!! It depends on the direction of the vector $\vec{r}$.

At equal distances, the electric field is more intense in the vertical direction to that of the displacement $(\theta=\pi/2)$ than in the direction of the displacement of the electric charge $(\theta=0)$.

If $v=0$, we fall back on the classic known expression:

$$\vec{E}=\frac{Q\vec{r}}{4\pi\varepsilon_0 r^3} \tag{12.3.366}$$

Remark

Let us recall that we have carried out (and continue in this sense) here a study of an electric charge in uniform rectilinear motion, that is to say at constant speed!

To find now the expression of the magnetic field $\vec{B}$, we introduce:

$$\vec{B}=(B'_x,B'_y,B'_z)=(0,0,0) \tag{12.3.367}$$

and:

$$\begin{aligned}E'_x&=E_x\\E'_y&=E_y\sqrt{1-\frac{v^2}{c^2}}\\E'_z&=E_z\sqrt{1-\frac{v^2}{c^2}}\end{aligned} \tag{12.3.368}$$

in:

$$\begin{aligned}B_x&=B'_x\\B_y&=\frac{B'_y-v\dfrac{E'_z}{c^2}}{\sqrt{1-\dfrac{v^2}{c^2}}}\\B_z&=\frac{B'_z-v\dfrac{E'_y}{c^2}}{\sqrt{1-\dfrac{v^2}{c^2}}}\end{aligned} \tag{12.3.369}$$

We therefore get:

$$B_x=0 \qquad B_y=-\frac{vE_z}{c^2} \qquad B_z=\frac{vE_y}{c^2} \tag{12.3.370}$$

Which are the components of:

$$\vec{B}=\vec{v}\times\vec{E}c^2 \tag{12.3.371}$$

To know $\vec{B}$ as a function of $\vec{r}$, we substitute the expression obtained for $\vec{E}$:

$$\boxed{\vec{B}=\frac{Q}{c^2\varepsilon 4\pi r^3}\frac{1-\dfrac{v^2}{c^2}}{\left[1-\dfrac{v^2}{c^2}\sin^2(\theta)\right]^{3/2}}\vec{v}\times\vec{r}} \tag{12.3.372}$$

In the case where the velocity is small, the relativistic term tends to 1 and the field $\vec{B}$ of an electric charge Q moving at the velocity v becomes:

$$\vec{B}=\frac{Q}{c^2\varepsilon 4\pi r^3}\vec{v}\times\vec{r}=\frac{\mu_0 Q}{4\pi r^3}\vec{v}\times\vec{r} \tag{12.3.373}$$

because as we have seen in the section of Electrodynamics (see page 4140):

$$\mu_0=\frac{1}{c^2\varepsilon_0} \tag{12.3.374}$$

Remarks

R1. At each location, the lines of the field $\vec{B}$ are contained in a plane perpendicular to the direction of motion of the electric charge Q (vector product oblige...!).

R2. If the moving electric charge is seen as a $\mathrm{d}Q$ attached to the point O', we can interpret its displacement at velocity v as a current I at a point of the referential O where O' is located. Therefore:

$$\mathrm{d}Q\vec{v}=\mathrm{d}Q\frac{\mathrm{d}\vec{x}}{\mathrm{d}t}=\frac{\mathrm{d}Q}{\mathrm{d}t}\mathrm{d}\vec{x}=I\mathrm{d}\vec{x} \tag{12.3.375}$$

Therefore:

$$\mathrm{d}\vec{B}(\vec{r})=\frac{\mu_0\mathrm{d}Q}{4\pi r^3}\vec{v}\times\vec{v}\times\vec{r}=\frac{\mu_0 I}{4\pi r^3}\mathrm{d}\vec{x}\times\vec{r} \tag{12.3.376}$$

We then fall back here the "Biot and Savart law" as proved in the section of Electromagnetism. So this a success of the Special Relativity theory again!!!

It is interesting to remember that an electric charged particle in motion will be seen in the frame of reference of the particle as emitting no electromagnetic field (there will be just an electrostatic field). This is not the case for a repository at rest. There is thus here a sort of flagrant counter-intuitive contradiction.

But this poses another problem, in a fast-moving frame of reference, a charged particle normally emits an acceleration radiation (see section Electrodynamics page 4163), this radiation in quantum mechanics must necessarily be accompanied by the emission of a quanta, which exists either or does not exist (a medium term does not exist). The very existence of photons would therefore be purely relative. And yet it is! Some particles have only a relative existence!!!! The complicated answer is therefore to know what the photons have become.

But here we reach the limit of what we master perfectly in the physics of the end of the 120th century (holocene calendar), because we speak of accelerated references frames (which implies to be in General Relativity and not the special one) and quantum field theory. The rigorous framework for dealing with this (which would encompass Quantum Gravitation) does not yet exist as far as we know. But a first step has been taken with the development of the Quantum Field Theory in curved space.

12.3.2.10.1 Tensor field transformation

We have seen and proved in the section of Electrodynamics that the whole electromagnetic field was summarized by the tensor of the same name (see page 4121). It would then be good to look at how this tensor transforms itself and if it does so correctly in relation to the results obtained above.

Let us consider the transformation (where the tensor of the electromagnetic field is in natural units !!!):

$$\boxed{F'^{\mu\nu}=L^{\mu}_{\nu}L^{\nu}_{\beta}F^{\alpha\beta}} \tag{12.3.377}$$

with the tensor of the electromagnetic field in contravariant components in the Minkowski metric $+---$:

$$F^{\mu\nu}=\begin{bmatrix}0 & -E_x & -E_y & -E_z\\ E_x & 0 & -B_z & B_y\\ E_y & B_z & 0 & -B_x\\ E_z & -B_y & B_x & 0\end{bmatrix} \tag{12.3.378}$$

And also by construction:

$$F'^{\mu\nu}=\begin{bmatrix}0 & -E'_x & -E'_y & -E'_z\\ E'_x & 0 & -B'_z & B'_y\\ E'_y & B'_z & 0 & -B'_x\\ E'_z & -B'_y & B'_x & 0\end{bmatrix} \tag{12.3.379}$$

Let us take, for example, the velocity parallel to the x-axis, then we have proved above that:

$$L=\begin{bmatrix}\gamma & -\beta\gamma & 0 & 0\\ -\beta\gamma & \gamma & 0 & 0\\ 0 & 0 & 1 & 0\\ 0 & 0 & 0 & 1\end{bmatrix} \tag{12.3.380}$$

Therefore:

$$L^0_0=\gamma \qquad L^0_1=-\beta\gamma \qquad L^1_0=-\beta\gamma \qquad L^2_1=\gamma \tag{12.3.381}$$

where as we can see, it is often customary in the field of Special Relativity and Electrodynamics to number the components of matrices / tensors starting from 0 (instead of 1 for most of the other chapters of this textbook).

We calculate the transformation (remember that the tensor of the electromagnetic field is antisymmetric!):

$$\begin{aligned}F'^{01}&=L^0_{\alpha}L^1_{\beta}F^{\alpha\beta}=L^0_0L^1_0F^{00}+L^0_1L^1_0F^{10}+L^0_0L^1_1F^{01}+L^0_1L^1_1F^{11}=L^0_1L^1_0F^{10}+L^0_0L^1_1F^{01}\\&=\beta^2\gamma^2F^{10}+\gamma^2F^{01}=F^{01}\gamma^2(1-\beta^2)=F^{01}\end{aligned} \tag{12.3.382}$$

We thus deduce, for the electric field (which corresponds perfectly to what we obtained above):

$$E'_x=E_x \tag{12.3.383}$$

We make a second calculation for the perpendicular component:

$$F'^{02}=L_\alpha^0 L_\beta^2 F^{\alpha\beta}F^{\alpha\beta}=L_\alpha^0 F^{\alpha 2}=L_0^0 F^{02}+L_1^0 F^{12} \quad (12.3.384)$$

hence:

$$-E'_y=\gamma(-E_y+\beta B_z)\Rightarrow E'_y=\gamma(E_y-vB_z) \quad (12.3.385)$$

which again corresponds perfectly to what we had obtained earlier above (in natural units, do not forget that we then have $\beta=v$)!

The same applies to the magnetic field:

$$F'^{23}=L_\alpha^2 L_\beta^3 F^{\alpha\beta}=F^{23}\Rightarrow B'_x=B_x \quad (12.3.386)$$

and:

$$F'^{12}=L_\alpha^1 L_\beta^2 F^{\alpha\beta}=L_\alpha^1 F^{\alpha 2}=L_1^1 F^{12}+L_0^1 F^{02}=\gamma F^{12}-\gamma\beta F^{02} \quad (12.3.387)$$

Which gives (in natural units, again do not forget that we then have $\beta=v$)! :

$$-B'_z=\gamma(-B_z+\beta E_y)\Rightarrow B'_z=\gamma(B_z-vEy) \quad (12.3.388)$$

etc.

12.3.3 Minkowski space-time

We have proved earlier above that:

$$t=\frac{t'}{\sqrt{1-\dfrac{v^2}{c^2}}} \quad (12.3.389)$$

Let us write this in the form:

$$\frac{t'^2}{t^2}=1-\frac{v^2}{c^2} \quad (12.3.390)$$

Let us multiply the two members by $(ct)^2$:

$$\frac{t'^2c^2t^2}{t^2}=c^2t^2-\frac{v^2c^2t^2}{c^2} \quad (12.3.391)$$

which gives us:

$$t'^2c^2=c^2t^2-v^2t^2 \quad (12.3.392)$$

If $v=c$ the equation vanishes:

$$t'^2c^2=0 \quad (12.3.393)$$

This result translates the fact that the dimensions of space and time are as stopped in the relativistic referential, because the relative speed of the object is equal to that of the light!

Let us now imagine that a light beam is emitted at the instant $t=0$ and propagates from the origin of a referential. We know that in space-time (application of the Pythagoras theorem in three-dimensional Euclidean space for recall...) the distance travelled by the photon is:

$$c=\frac{\sqrt{x^2+y^2+z^2}}{t} \tag{12.3.394}$$

By changing t of member and bringing the whole to the square to remove the root, we get:

$$ct=\sqrt{x^2+y^2+z^2}\Leftrightarrow ct^2=x^2+y^2+z^2 \tag{12.3.395}$$

Therefore:

$$ct^2-(x^2+y^2+z^2)=0 \tag{12.3.396}$$

Remark

We can assimilate this relation to the representation of a spherical wavefront of a light wave propagating at the speed of light (see the equation of a sphere originally centered in the section of Analytical Geometry).

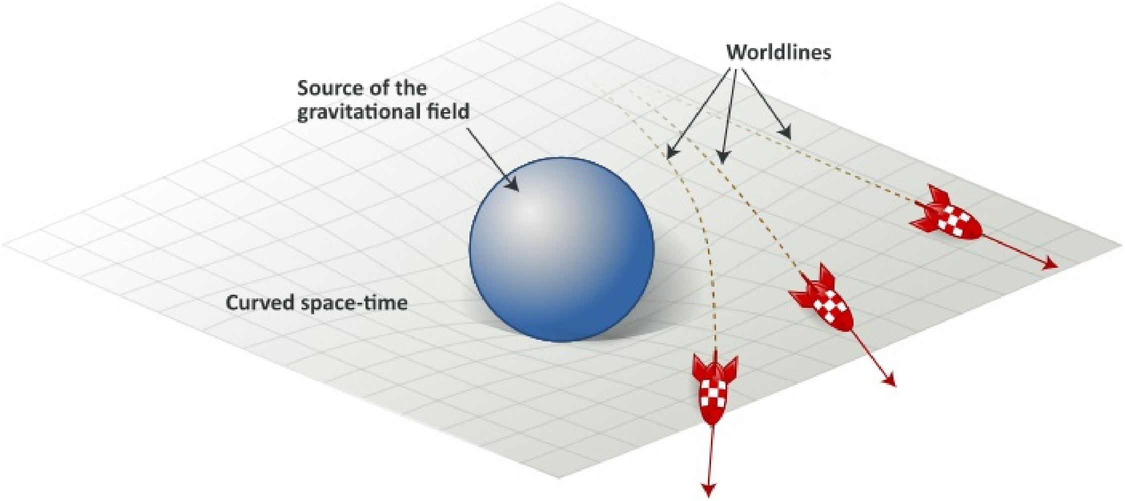
Let us now consider two coordinate events (x_1,y_1,z_1,t_1) and (x_2,y_2,z_2,t_2) and we denote by $\mathrm{d}s$ the "space-time abscissa" (or "proper-distance"). We can then write the spatio-temporal interval as such:

$$(\mathrm{d}s^2)=c^2(t_2-t_1)^2-\left((x_2-x_1)^2+(y_2-y_1)^2+(z_2-z_1)^2\right) \tag{12.3.397}$$

By passing to the limit, we get the famous quadratic form of the "interval invariant":

$$\boxed{\mathrm{d}s^2=c^2\mathrm{d}t^2-(\mathrm{d}x^2+\mathrm{d}y^2+\mathrm{d}z^2)=c^2\mathrm{d}t^2-\mathrm{d}L^2} \tag{12.3.398}$$

which has the same shape and value regardless of the reference system considered as we have already proved it earlier above. The infinitesimal interval of space-time $\mathrm{d}s^2$ between two infinitely neighbouring events is therefore a relativistic invariant that we often name the "space-time curvilinear abscissa" or more simply the "worldline" (an observer "riding" the worldline does not see - or "feel" - himself moving through space if he no have any observable reference object visible, only through time or more exactly it's "proper time" as we already know it).



Worldlines
Source of the gravitational field
Curved space-time

Figure 12.212: **Worldline**

It is the interval of space-time or, as Albert Einstein simply said, the "square of distance" .... The fact that this magnitude may be positive, negative (!) or zero is linked to the absolute character of the speed of light (we will come back to this later).

Remark

Equivalently we have $\mathrm{d}s^2=-c^2\mathrm{d}t^2+(\mathrm{d}x^2+\mathrm{d}y^2+\mathrm{d}z^2)$. That we can rewrite as $\mathrm{d}s^2=c^2\mathrm{d}(\mathrm{i}t)^2+(\mathrm{d}x^2+\mathrm{d}y^2+\mathrm{d}z^2)$. Therefore imaginary times makes space-time Euclidean.

We can also now turn our attention to the relativistic character of this metric. If it is invariant, it must also be invariant by Lorentz transformations. We then say that "the metric is invariant by Lorentz transformation". Such a transformation can be found on the basis of that used for the tensor of the electromagnetic field (see above). The reader will readily verify from the detailed example of the electromagnetic field that for the metric tensor we have the relation (as always we can detail on request if necessary):

$$\eta'_{\mu\nu}=L_\alpha^\mu L_\beta^\nu \eta_{\mu\nu} \tag{12.3.399}$$

The curvilinear abscissa can also be expressed by the norm of the quadrivector displacement which we defined above as (ct,x,y,z). Indeed, the norm (see section Tensor Calculus page 2051) is written by taking down the indices using the "Minkowski metric" $\eta_{\mu\nu}$ or "pseudo-Riemannian metric":

$$\mathrm{d}s^2=\mathrm{d}x^\nu(\eta_{\mu\nu}\mathrm{d}x^\nu)=\eta_{\mu\nu}\mathrm{d}x^\nu\mathrm{d}x^\nu=\mathrm{d}x^\nu\mathrm{d}x_\nu=c^2\mathrm{d}t^2-\mathrm{d}x^2-\mathrm{d}y^2-\mathrm{d}z^2 \tag{12.3.400}$$

with the definition of the "Minkowski's matrix" (we will return to this in detail at the beginning of our study of General Relativity):

$$\eta_{\mu\nu}=\begin{bmatrix}1&0&0&0\\0&-1&0&0\\0&0&-1&0\\0&0&0&-1\end{bmatrix} \tag{12.3.401}$$

where as usual in this textbook we make the abuse of notation (already mentioned in the section of Tensorial Calculation) not to put $\eta_{\mu\nu}$ in brackets (since a tensor and its matrix form are normally two distinct things in rigorously speaking).

If we put the following two relations in correspondence:

$$c^2t^2-(x^2+y^2+z^2)=0 \qquad \text{and} \qquad \mathrm{d}s^2=c^2\mathrm{d}t^2-(\mathrm{d}x^2+\mathrm{d}y^2+\mathrm{d}z^2) \tag{12.3.402}$$

we then have $\mathrm{d}s^2=0$ when the two events are connected to the speed of light.

Moreover, if we put:

$$\mathrm{d}x^2+\mathrm{d}y^2+\mathrm{d}z=\mathrm{d}r^2 \tag{12.3.403}$$

we can then write:

$$\boxed{\mathrm{d}s^2+\mathrm{d}r^2=c^2\mathrm{d}t^2} \tag{12.3.404}$$

This is nothing more than the equation of a cone (see section Analytical Geometry page 2823) of axis of ordinate $c^2\mathrm{d}t^2$... the famous "light cone of Universe" (to which we devote a study further below). Every event is therefore by extension in this cone and the evolution of any system can thus be described (by its spatial and temporal position), by what we name its "line of Universe" or "World line". The Universe line of a particle is therefore the sequence of events it unfolds during its lifetime.

12.3.3.1 Four-vectors

We have just defined what Minkowski's metric was, we can now correctly define the concept of quadrivector that we have already addressed without always knowing what we were doing.

Definition (#12.3.541): In a four-dimensional space of Minkowski type, the four quantities:

$$K^{\nu}=(K_t,K_x,K_y,K_z) \tag{12.3.405}$$

(regardless of the order of terms for this definition or whether the indices are numbers or letters corresponding to the four spatio-temporal components) form a covariant "four-vector" if they transform following the Lorentz transformation:

$$\begin{aligned} K'_x&=\gamma(K_x-\beta K_t) & K_x&=\gamma(K'_{x'}+\beta K'_{t'})\\ K'_y&=K_y & K_y&=K'_y\\ K'_z&=K_z & K_z&=K'_z\\ K'_t&=\gamma(K_t-\beta K_x) & K_t&=\gamma(K'_{t'}+\beta K'_{x'}) \end{aligned} \tag{12.3.406}$$

The "pseudo-norm" of a quadrivector in a Minkowski space of metric $\eta_{\mu\nu}$ is then:

$$K^{\mu}K_{\mu}=K^{\mu}(\eta_{\mu\nu}K^{\mu})=K_t^2-K_x^2-K_y^2-K_z^2 \tag{12.3.407}$$

where we see that the contravariant four-vector multiplied by the metric returns the contravariant four-vector (see section Tensor Calculus page 2059).

The following quantity being invariant by change of Galilean referential as we proved it almost at the beginning of this section:

$$K_{\mu}K^{\mu}=K'_{\mu}K'^{\mu} \tag{12.3.408}$$

This property of invariance by change of Galilean referential of the four-vector is their main property. Thus, two observers in relative motion, which are uniform in relation to each other, must compare the results of the same measure using the norm of the four-vectors. Similarly, the laws they seek to determine to be as general as possible must use these invariant quantities!

We can also write the norm of a four-vector in the form:

$$\begin{aligned} K_{\nu}K^{\nu}&=K_0K^0+K_1K^1+K_2K^2+K_3K^3\\ &=(K_0)^2-(K_1)^2-(K_2)^2-(K_3)^2\\ &=(K^0)^2-(K^1)^2-(K^2)^2-(K^3)^2\\ &=(K^0)^2-\|\vec{K}\|^2 \end{aligned} \tag{12.3.409}$$

and the four-vector themselves:

$$K^{\nu}=(K^0,\vec{K}) \qquad K_{\nu}=(K_0,-\vec{K}) \tag{12.3.410}$$

So for summary let us give the list of the four-vectors we have determined so far in this section but by standardizing the notations (and only those four-vectors that will be useful for other sections of this textbook!):

- The space-times four-vector ("four-position"):

$$x^{\nu}=(ct,x,y,z)=(ct,\vec{x}) \tag{12.3.411}$$

- The velocity four-vector ("four-velocity"):

$$u^{\nu}=\gamma(\vec{v})(c,v_x,v_y,v_z)=\gamma(\vec{v})(c,\vec{v}) \tag{12.3.412}$$

- The current four-vector ("four-current"):

$$j^{\nu}=\rho_0\gamma(\vec{v})(c,\vec{v}) \tag{12.3.413}$$

- The acceleration four-vector ("four-acceleration"):

$$a^{\nu}=\gamma^4\left(\vec{\beta}\circ\vec{a},\vec{a}+\vec{\beta}\times(\vec{\beta}\times\vec{a})\right) \tag{12.3.414}$$

- The energy-momentum four-vector ("four-momentum"):

$$p^{\nu}=\left(\frac{E}{c},p_x,p_y,p_z\right)=\left(\frac{E}{c},\vec{p}\right)=m\gamma(\vec{v})(c,\vec{v}) \tag{12.3.415}$$

- The gradient four-vector ("four-gradient") introduced in the section of Tensor Calculus:

$$\vec{\partial}=\left(\frac{\partial}{\partial x_0},-\frac{\partial}{\partial x_1},-\frac{\partial}{\partial x_2},\frac{\partial}{\partial x_3}\right)=\left(\frac{1}{c}\frac{\partial}{\partial t},-\nabla\right) \tag{12.3.416}$$

Obviously we have considered here four-vectors in the context of Special Relativity. Although the concept of four-vectors also extends to General Relativity, some of the results stated above require modification in General Relativity.

12.3.3.2 Universe light cone

The topology of the light cone has its origin in the relations of anteriority and posteriority of relativistic events, which makes it possible to distinguish between an event in the past of another or in the future of it.

The principal objective of the light cones in the popularization works of theoretical physics is to map out the history of light pulses emitted at a point in the space where certain conditions may prevail. The points are represented in space by a series of snapshots at various times t_1, t_2, t_3, etc. (see figure below), the spherical wave front of the light magnifying in space. In space-time, the same event (at the bottom on the figure) is represented by a "light cone", whose apex is the point of emission.

On a sheet of paper, we have to remove one of the spatial dimensions. The spatial axes are drawn in the horizontal plane and the time axis directed upwards. The cone sections at the instants t_1, t_2, t_3 correspond to the snapshots of the spatial representation: the two-dimensional wavefronts are circles whose radius is that of the spherical wavefront at the instant considered.

The light cone shows in a single diagram the continuous history of the wavefront of a light signal.

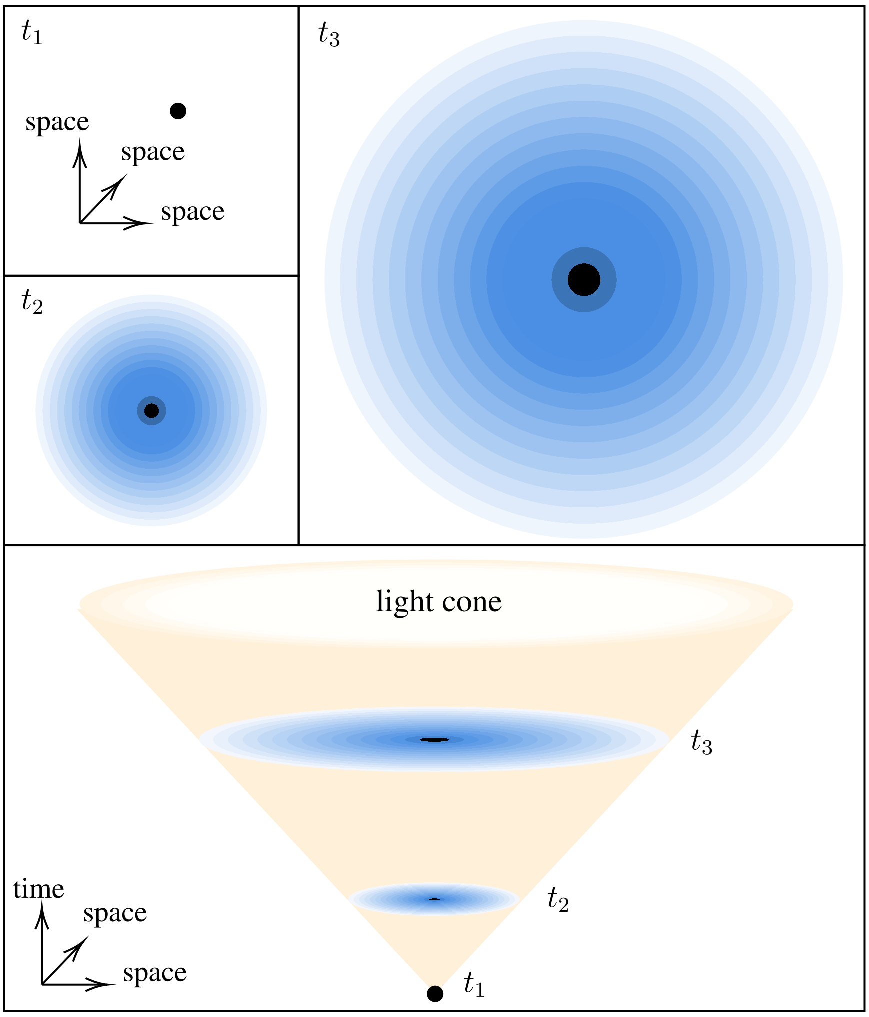


Figure 12.213: **Idea of light-cone**

More precisely, the "snapshots" mentioned above are named "punctual events" and these appear instantaneous (approximation based on geometric optics) to any observer capable seeing them. A collision between two point particles provides an example of a punctual event. It is quite possible that a non-punctual instantaneous event appears instantaneous to a certain observer but, because of the finite propagation velocity of the light, not instantaneous to another observer.

Definitions (#12.3.542):

D1. Two punctual events occupy the same "time-space point" if they appear simultaneously to any observer able to see them.

D2. The set M of all points of space-time is named the "space-time" and it is a mathematical model that fuses the three dimensions of space and the one dimension of time into a single four-dimensional space continuum.

More technically, space-time is a pseudo-Riemannian manifold (for reminder a manifold is a topological space that is locally homeomorphic to Euclidean space and pseudo-

Riemannian means that is equipped with a metric tensor that is everywhere nondegenerate[41]) and that is most of the time[42] Lorentz invariant (for reminder Lorentz invariance refers to the invariance of physical laws under Lorentz transformations, which include boosts - velocity changes - and rotations in four-dimensional space-time) in $\mathbb{R}^4$.

D3. The boundary defined by the Universe cone is named the "cosmological horizon"

Let us recall that if no force acts on a point particle, we say from it that is an "inertial" or "free" particle. We also say that it is in "inertial motion".

Given the point p, $N(p)$ is an absolute geometric structure independent of the observer. Its future component will be denoted $N^+(p)$; Its past component $N^-(p)$ and it will be represented by the following cone:

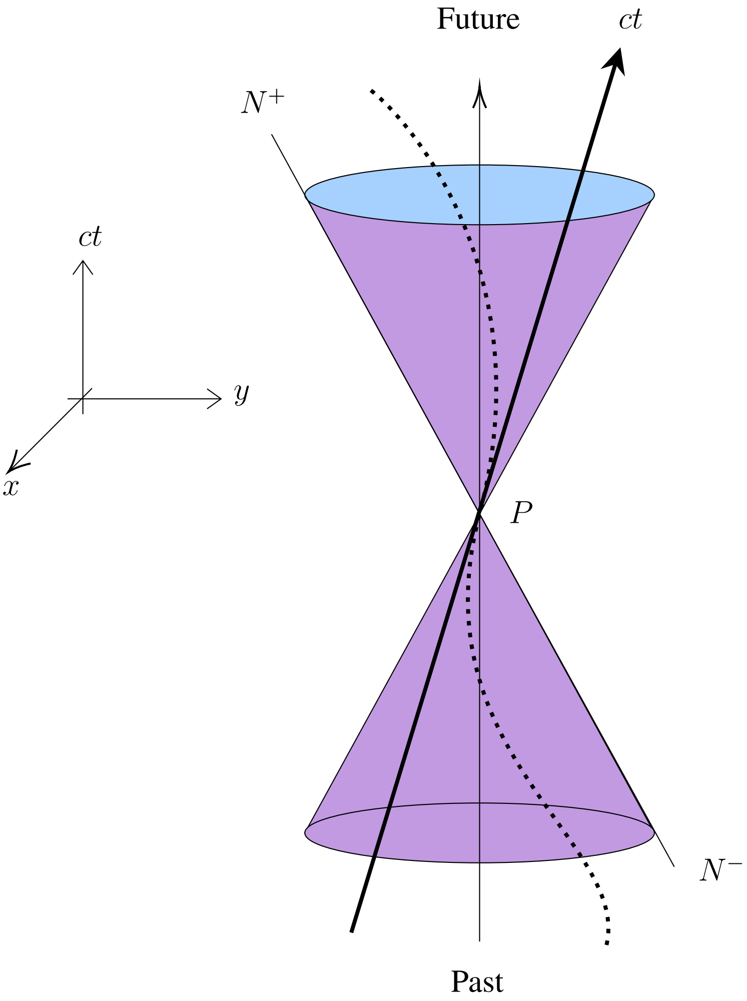

Figure 12.214: **Past and future light cones of an event of a worldline**

Indeed, let us recall that the Minkowski equation is invariant since:

$$c\mathrm{d}t'^2-(\mathrm{d}x'^2+\mathrm{d}y'^2+\mathrm{d}z'^2)=c\mathrm{d}t^2-(\mathrm{d}x^2+\mathrm{d}y^2+\mathrm{d}z^2) \qquad (12.3.417)$$

---

[41] Unlike Riemannian manifolds (where the metric is positive-definite), pseudo-Riemannian manifolds allow for more general metric signatures.

[42] Minkowski and Schwarzschild metric are Lorentz invariant but for example the Roberstswon-Walker metric among many others... is not Lorentez invariant.

We have, when we reduced to three parameters (we remove a spatial dimension to simplify the conceptualisation), if the punctual events are related to the speed of light (see earlier above):

$$c\mathrm{d}t^2-(\mathrm{d}x^2+\mathrm{d}y^2)=0 \qquad (12.3.418)$$

What we can also write in the form:

$$c\mathrm{d}t^2=(\mathrm{d}x^2+\mathrm{d}y^2) \qquad (12.3.419)$$

to be compared with the equation of a cone (see section Analytical Geometry page 2823):

$$(z\tan(\theta))^2=x^2+y^2 \qquad (12.3.420)$$

when we put $c=1$ (which is frequent in theoretical physics as we have already mentioned many times).

Therefore the Minkowski equation can be indeed presented by a cone.

Remark

If we would have keep the three spatial parameters and the time interval constant, the reader will then perhaps have noticed that we would fall back neither on the equation of a cone but on that of a sphere. It is the "celestial sphere" where at a given instant, on its surface, multiple cones of light are created.

The universe line of any observer which occupies instantly p and whose line of the Universe passes through p itself, is contained within $N(p)$ defined by a single point on its celestial sphere (the one that is described by the information vector - the photon - in all directions of space). This means that there can be, in extenso, as many null rays (foci of cones) passing through p as points on a sphere.

The following example will (we hope) appear more obvious:

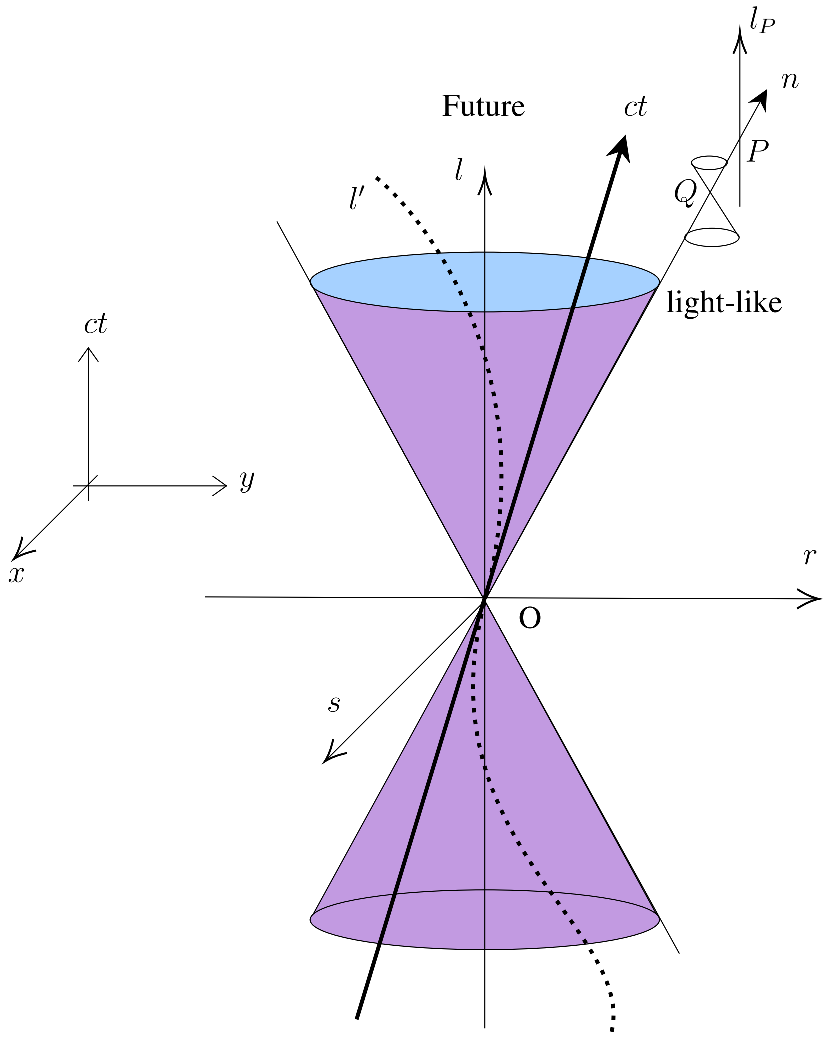

Figure 12.215: **Universe Line Principle with its associated cone**

As illustrated in the figure above, a light event at the point O of the space-time produces a beam of photons, all in the zero cone of the future O, $N^+(\mathrm{O})$ (these photons have been emitted by atoms in various states of movements whose universe lines l and l' pass through O, but are entirely contained within the $N^+(\mathrm{O})$). The universe line n can only be described by a particle moving at the speed of light because it defines the boundary of the cone (we then say that the line of the Universe is of "light type").

Remark

The representation of the Universe lines in the lower part (inverted cone) comes from the fact that an event can also have a past... so the scheme generalizes the particular example.

Let l_p be the universe line of a stationary person P (hence the verticality of its Universe line in the figure above) and n that of a light ray having the origin O. Both lie in the four dimension space and they intersect at a single point P. The points O and P lie on a zero radius (of a cone of the future), n, of $N^+(\mathrm{O})$. In P, the person P sees a sudden flash in the direction defined by n, for him the direction of the luminous event (described only by its velocity therefore, so a universe line of an inertial particle can be described only by time and speed).

An atom whose Universe line cuts n at the point Q absorbs a photon of the luminous event O and re-emits a beam of photons shortly after. These, in turn, form zero rays in $N^{+}(Q)$, but only those of direction n will reach the person P and will be seen by him at the point P.

If P is inside $N(\mathrm{O})$, the zero cone of O, we will say that its universe line is of the "time type". In this case, O and P are located on the universe line of an observer or a massive particle. There are, of course, two types of time displacement:

1. If P is in the future of O (according to an observer whose universe line passes through O and P), we will say that P "points to the future".
2. If not, we will of course say that it "points to the past".

If P is on $N(\mathrm{O})$ - that is to say on the surface of the cone - then we say that it is "null" or of "light type" and if P is neither zero nor of time, then P is outside of $N(\mathrm{O})$ and then we say that it is of "space type":

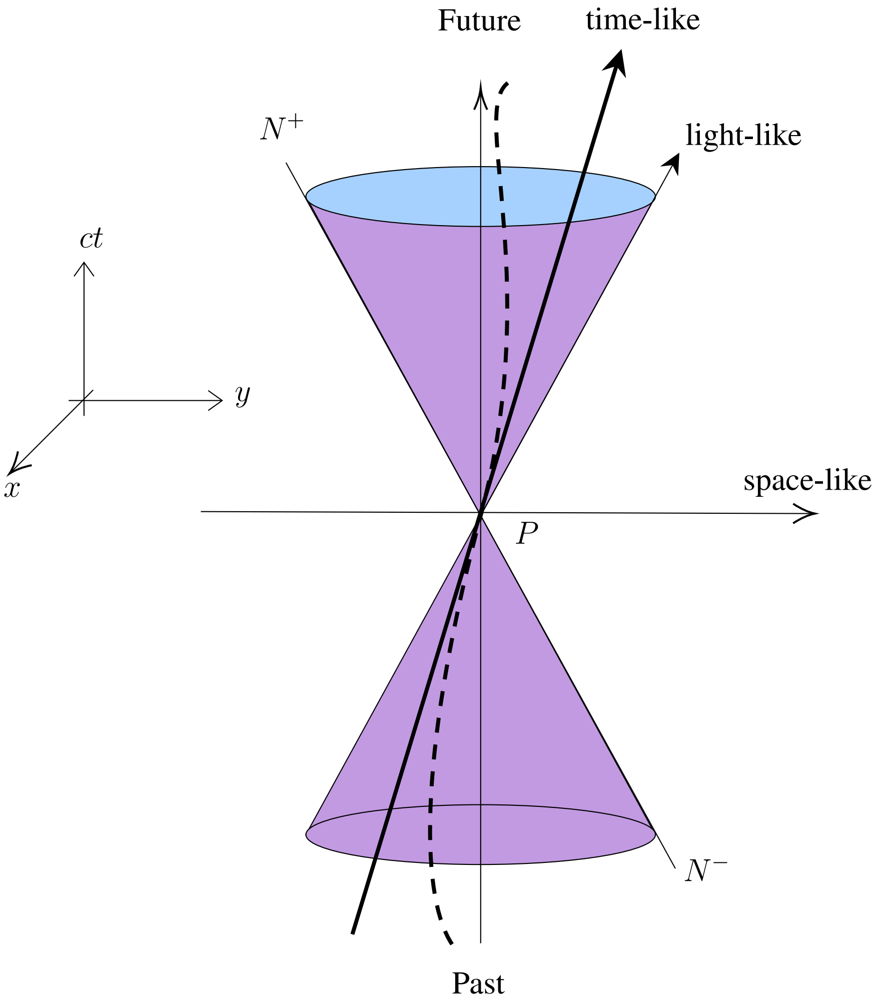

Figure 12.216: Types of universe lines

This is mathematically translated by remembering (see above) that the invariant interval (in the case of the Minkowski metric) is given by:

$$\mathrm{d}s^2=\mathrm{d}x^{\nu}(\eta_{\mu\nu}\mathrm{d}x^{\nu})=\mathrm{d}x^{\nu}\mathrm{d}x_{\nu}=c^2\mathrm{d}t^2-\mathrm{d}x^2-\mathrm{d}y^2-\mathrm{d}z^2 \quad (12.3.421)$$

- $\mathrm{d}s^2=0$ (then $r^2=c^2\Delta^2$): The universe line is therefore "light-like" and it is that latter which describes the surface of the cone by definition (according to what we have demonstrated previously and whatever the choice of the metric) is such that:

  $$c^2\mathrm{d}t^2=\mathrm{d}x^2+\mathrm{d}y^2+\mathrm{d}z^2 \tag{12.3.422}$$

  which is the case of a photon (hence the name ...). In other words, the spatial separation is equal to the distance light travels.

- $\mathrm{d}s^2<0$ (then $r^2<c^2\Delta^2$: We then say that the Universe line is "space-like", therefore such that:

  $$c^2\mathrm{d}t^2<\mathrm{d}x^2+\mathrm{d}y^2+\mathrm{d}z^2 \tag{12.3.423}$$

  Two events that take place simultaneously but at different places are therefore space-like. In other words, the spatial separation is less than the distance light travels.

- $\mathrm{d}s^2>0$ (then $r^2>c^2\Delta^2$: We then say that the Universe line is "time-like", therefore such that:

  $$c^2\mathrm{d}t^2>\mathrm{d}x^2+\mathrm{d}y^2+\mathrm{d}z^2 \tag{12.3.424}$$

  In other words the spatial separation is greater than the distance light travels.

Figure 12.217: **Light Cone in 2d Space plus a Time Dimension**

Let us return to our equations after this small interlude ... the equations therefore lead us to several observations. Thus, in the four-dimensional Euclidean Universe of Minkowski, the trajectories of objects in space-time are always straight lines. Indeed, the trivial example consists in considering that the object remains at rest, then only the time then continues to flow. We have therefore:

$$t'^2c^2 = c^2t^2 - v^2t^2 \qquad (12.3.425)$$

by putting $v = 0$, this gives us:

$$c^2t'^2 = c^2t^2 \qquad (12.3.426)$$

therefore:

$$c^2\mathrm{d}t'^2 = c^2\mathrm{d}t^2 \qquad (12.3.427)$$

hence:

$$\mathrm{d}s^2 = c^2\mathrm{d}t^2 \qquad (12.3.428)$$

and also:

$$\mathrm{d}s = c\mathrm{d}t' \qquad (12.3.429)$$

The primitive being (integration constant taken as zero):

$$s = ct' \qquad (12.3.430)$$

which is indeed a straight line and therefore represents the universe line of the object considered in the universe cone. We can also observe that in this case, the evolution of the phenomenon is purely temporal when the interval is positive (which supports what we said earlier).

Now to be sure things are crystal clear....! Imagine computing the interval:

$$\Delta s^2 = (c\Delta t)^2 - \left(\Delta x^2 + \Delta y^2 + \Delta z^2\right),$$

between two events on the worldlines of a massless particle and of a massive particle. This interval will have the same value not matter which inertial reference frame is used to compute it. For the massive particle, we can simplify the computation by choosing to do the calculation in its rest frame. There the space part of the interval is zer and we have

$$\Delta s^2 = (c\Delta t_{\text{rest}})^2 - (\text{ zero })$$

which you used to define the proper time, τ, between the two events.

For the massless particle, that doesn't work: no reference frame exists where the massless particle is at rest. Instead, the massless particle is observed to travel at speed c in all reference frames. The only freedom we have is to orient the velocity along one axis, so that we can say e.g.:

$$\Delta x = c\Delta t \quad \Delta y = \Delta z = 0$$

For this case the interval is:

$$\Delta s^2 = (c\Delta t)^2 - (c\Delta t)^2 = 0$$

which explains why we say that a photon doesn't experience time! Another way to see that is to remember that definition of the proper time interval, for a particle with an arbitrary motion $\vec{v}$ in a reference frame $\mathcal{R}$ between times t_1 and t_2 in this reference frame, is:

$$\Delta\tau = \tau_2 - \tau_1 = \int\limits_{t_1}^{t_2} \mathrm{d}\tau = \int\limits_{t_1}^{t_2} \sqrt{1 - \frac{\vec{v}(t)^2}{c^2}}\mathrm{d}t$$

So, if the particle is a photon, $\vec{v}(t)^2 = c^2$ which leads to $\mathrm{d}\tau = 0$ and $\Delta\tau = 0$: the proper time that elapses between any two events on the world line of a photon is zero!

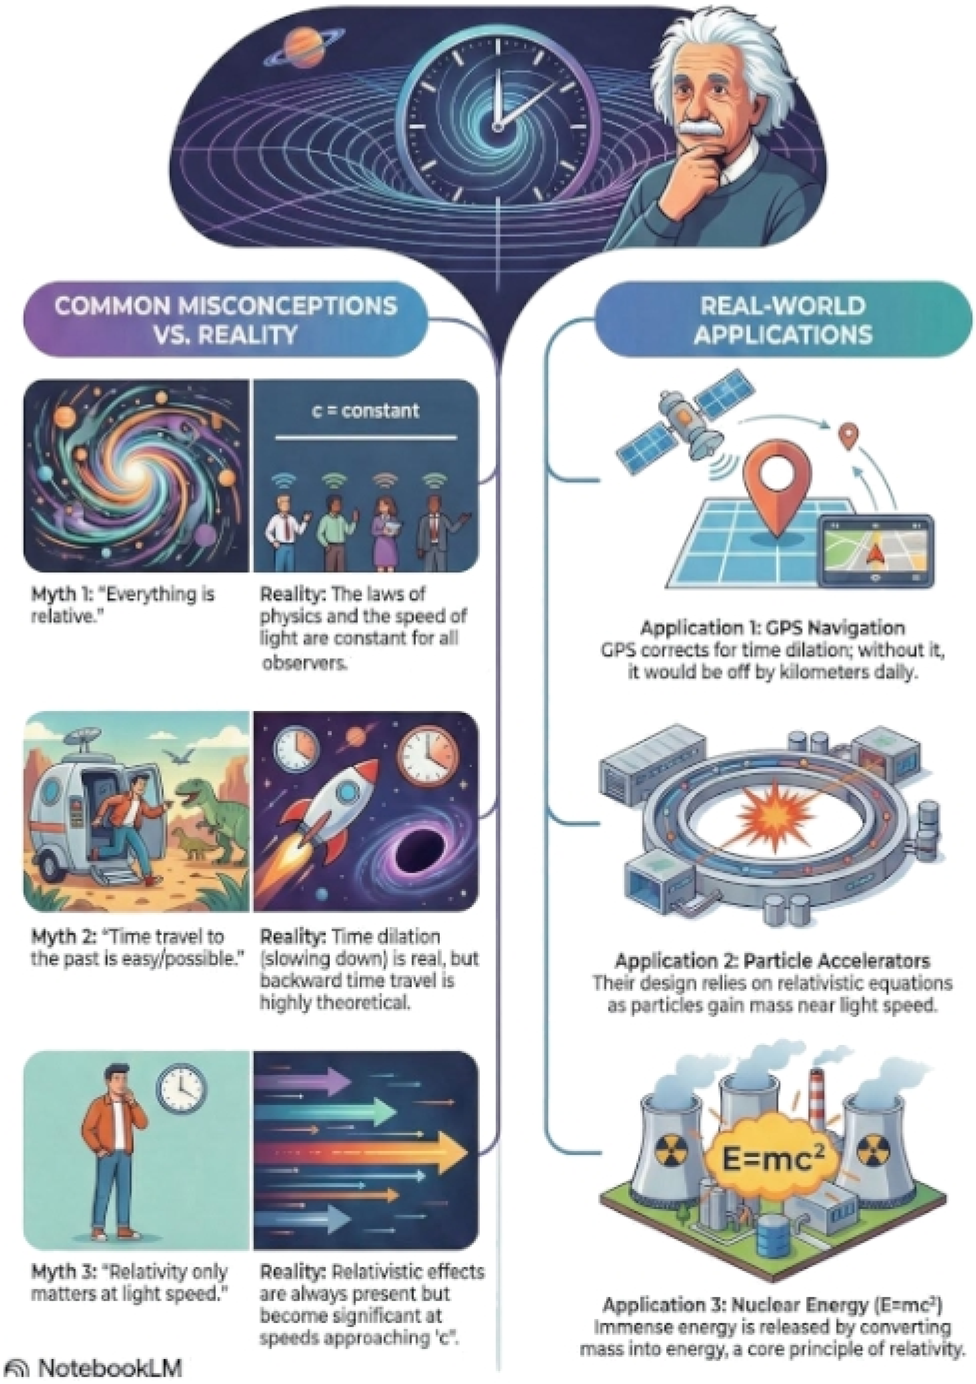
Remarks

R1. If the speed of light is infinite, we fall back on the particular case of the Newtonian universe, where a phenomenon can instantly occur. Time is absolute and there is no cosmological horizon because the cone has a maximum aperture (right angle).

R2. If we put that the velocity of light as equal to 1 (natural units), as we have done it already sometimes, the axis of the ordinate of the cone is named a "purely temporal axis".

R3. It is necessary to understand that our Universe has its own cone of Universe (cone... if the space is of Minkowsky-like of course...).

Finally, let us say that the theory of Special Relativity, like that of General Relativity, does not impose a given number of spatial dimensions in order to remain consistent: this is a pity for theoretical physicists who would like a theory which, imposes on itself a finite number of dimensions to remain consistent (that on the other hand the theory of the strings or superstring).



Myth 1: "Everything is relative."

Reality: The laws of physics and the speed of light are constant for all observers.

Myth 2: "Time travel to the past is easy/possible."

Reality: Time dilation (slowing down) is real, but backward time travel is highly theoretical.

Myth 3: "Relativity only matters at light speed."

Reality: Relativistic effects are always present but become significant at speeds approaching 'c'.

Application 1: GPS Navigation
GPS corrects for time dilation; without it, it would be off by kilometers daily.

Application 2: Particle Accelerators
Their design relies on relativistic equations as particles gain mass near light speed.

Application 3: Nuclear Energy ($E=mc^2$)
Immense energy is released by converting mass into energy, a core principle of relativity.

12.3.4 Empirical evidence of Special Relativity theory

We will now review the 7 classical experimental checks of the 120th century (holocene calendar) of the Special Relativity theory which are:

1. **Michelson-Morley Experiment:** An interferometer was used to compare the speed of light in different directions as Earth moved through space. No measurable difference in the interference pattern was observed. This result showed that the speed of light is the same in all directions and does not depend on the motion of the observer, exactly as

predicted by Special Relativity.

2. **Muon Lifetime (Time Dilation):** Muons are unstable particles created in the upper atmosphere that normally decay very quickly. Despite their short lifetime, many more muons reach Earth's surface than classical physics predicts. This occurs because time passes more slowly for rapidly moving muons, providing direct evidence of relativistic time dilation.

3. **Relativistic Doppler Effect:** Light from stars and other astronomical objects changes wavelength when the source moves relative to the observer. Objects moving away produce a redshift, while objects moving toward the observer produce a blueshift. The measured wavelength shifts match the relativistic Doppler formula and confirm Einstein's theory.

4. **Relativistic Aberration of Light:** The apparent position of stars changes when the observer is moving relative to the incoming light. The observed shift in direction follows the exact relationship predicted by Special Relativity. This demonstrates that measurements of direction in space depend on the relative motion between source and observer.

5. **Mass-Energy Equivalence:** Nuclear reactions can transform a small amount of mass into a large amount of energy. The energy released is quantitatively consistent with the famous equation $E = mc^2$. These observations confirm that mass and energy are equivalent manifestations of the same physical quantity.

6. **Particle Acceleration Near Light Speed:** Experiments with particle accelerators show that particles require increasingly larger amounts of energy as their speeds approach the speed of light. Even enormous increases in energy produce only small increases in velocity near this limit. These results confirm the relativistic prediction that no object with mass can be accelerated to the speed of light.

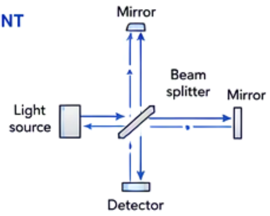
7. **GPS Satellites:** Clocks carried by GPS satellites do not tick at the same rate as clocks on Earth's surface because the satellites are moving at high speed. Relativistic corrections must be continuously applied to maintain accurate positioning. The everyday success of GPS navigation provides a practical and continuously operating verification of Special Relativity.

EXPERIMENTAL EVIDENCE OF
SPECIAL RELATIVITY

Nature consistently confirms the predictions of Einstein's theory.

1 Michelson–Morley Experiment (1887)

An interferometer was used to detect Earth's motion through the "luminiferous ether". No shift in the interference pattern was observed.



WHAT IT SHOWS:

The speed of light is the same in all directions for all observers (no preferred frame of rest).

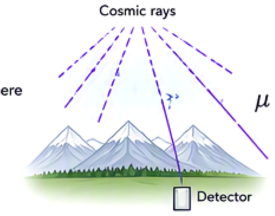
$$\boxed{\Delta L = 0}$$

KEY REFERENCE (PAPER):

A. A. Michelson, E. W. Morley, "On the Relative Motion of the Earth and the Luminiferous Ether", *American Journal of Science*, 34, 333–345 (1887).

2 Time Dilation: Muon Lifetime (1941)

Muons produced in the upper atmosphere reach Earth in larger numbers than expected because their lifetimes are dilated.



WHAT IT SHOWS:

Moving clocks run slower than at rest.

(Time dilation is real.)

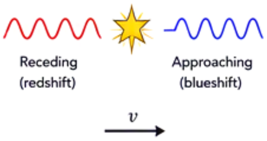
$$\boxed{\Delta t = \gamma \Delta t_0}$$

KEY REFERENCE (PAPER):

J. Clay, R. Van de Water, "Evidence for the Relativistic Time Dilation of Muons in Flight", *Physical Review*, 60, 872–873 (1941).

3 Relativistic Doppler Effect: Starlight Shift (1950s)

Light from stars moving relative to Earth shows the wavelength shift predicted by the relativistic Doppler formula.



WHAT IT SHOWS:

Observed wavelengths shift exactly as relativistic Doppler effect predicts.

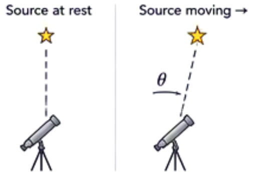
$$\frac{\lambda_{\text{obs}}}{\lambda_{\text{emit}}} = \sqrt{\frac{1+v/c}{1-v/c}}$$

KEY REFERENCE (PAPER):

W. W. Campbell, "Illustration of the Relativistic Doppler Effect in Stellar Spectra", *Physical Review*, 78, 230–237 (1950).

4 Relativistic Aberration of Light (1925)

The apparent position of stars shifts in the direction of motion, as predicted by special relativity.



WHAT IT SHOWS:

Light direction depends on the relative motion of the observer.

$$\cos\theta = \frac{\cos\theta'}{\gamma(1+\frac{v}{c}\cos\theta')}$$

KEY REFERENCE (PAPER):

W. W. Campbell, "The Aberration of Light According to the Theory of Relativity", *Astrophysical Journal*, 61, 357–371 (1925).

5 Relativistic Mass–Energy Equivalence (1932)

Nuclear experiments confirmed that mass can be converted into energy, with the exact amount predicted by $E = mc^2$.

Mass (m)
Energy (E)

WHAT IT SHOWS:

Mass and energy are equivalent.

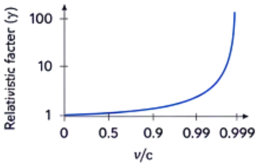
$$\boxed{E = mc^2}$$

KEY REFERENCE (PAPER):

C. D. Anderson, "The Positive Electron", *Physical Review*, 43, 491–494 (1933). (positron discovery)

6 Particle Acceleration Near Light Speed (1960s)

Electrons accelerated to speeds very close to c require increasingly more energy, as predicted by relativistic dynamics.



WHAT IT SHOWS:

As $v \to c$, γ increases without bound: more energy is needed to go faster.

$$\gamma = \frac{1}{\sqrt{1-v^2/c^2}}$$

KEY REFERENCE (PAPER):

M. Sands et al., "Observation of the High-Energy Behavior of Electrons in Storage Rings", *Physical Review Letters*, 5, 278–280 (1960).

7 GPS Satellites (Real-World Test)

GPS satellites experience time dilation due to both their speed and weaker gravity. Relativistic corrections are essential for meter-level accuracy.

WHAT IT SHOWS:

Relativity is required in everyday technology: time runs differently in moving frames.

KEY REFERENCE (PAPER):

T. M. Eubanks, "Relativistic Clock Synchronization", *GPS Solutions*, 6(3), 50–62 (2002). (Review of relativistic effects in GPS)

THE BIG PICTURE

Time is relative. Moving clocks run slower.

Space is relative. Distances and directions depend on motion.

Energy and mass are the same. $E = mc^2$

Across many experiments, all observations agree with the predictions of Special Relativity.

12.4. General Relativity

As we saw it, in the previous section, Special Relativity is a remarkable achievement from a theoretical point of view as well as a practical point of view, forming a continuum of space-time where the space variables and time are given the same physical dimension (that of a distance metric for reminder!). However, this applies only to the Euclidean frames and to inertial/Galileans reference frames (constant speed reminder...). It is therefore appropriate to first generalize the entire mechanic theory by expressing its principles and fundamental results in a generalized form independent of the type of coordinate system chosen (that is to say: independent of the space properties) using for this purpose tensor calculus and then to take into account the non-inertial systems. The equivalence of inertial systems by Special Relativity and the non-equivalence of inertial systems can then shortly be resumed (a little bit basically...) by saying that speed is relative but the acceleration is absolute! Thus, we can never rest distinguish a uniform motion, but we can distinguish them from an accelerated motion.

It should also be consider the fact that Special Relativity applies only to Galileans frames is restrictive because any mass generates a gravitational field whose scope is endless. To find a true Galilean frame, it is therefore necessary to lie infinitely far from any mass. Relativistic mechanics built from Special Relativity therefore constitutes an approximation of the laws of nature, where the gravitational fields or accelerations are low enough. This application limitation is not more suited to relativistic astrophysics whose activity has intensified in the late 120th century (holocene calendar).

Remark

Following multiple requests here is a summary of the differences between the textbook *Gravitation* (considered as an old reference) of C. W. Misner, K. S. Thorne, J. A. Wheel and *Opera Magistris* for the subjects related to Gravitation and Special/General Relativity: The content and topics covered are quite similar; however *Gravitation* lacks many detailed proofs. The notations and the technology used to write *Gravitation* is quite outdated (11973 according to holocene calendar) and can be a bit cumbersome to read (and in addition all the figures and the few photos are in grayscale...). If we calculate the ratio of pages sizes including all the margins, in 12024 (holocene calendar) the number of pages related to the subjects of Gravitation and General Relativity is almost identical in both textbooks (within about ten pages). Furthermore, the content of *Gravitation* isn't updated anymore since 11973 (holocene calendar) to reflect recent experimental observations, new parameter values, improved models and new speculative ones.

Definition (#12.4.543): "General Relativity", also known as the "general theory of relativity", and as "Einstein's theory of gravity", is the geometric theory of gravitation that generalizes Special Relativity and refines Newton's law of universal gravitation, providing a unified description of gravity as a geometric property of space and time, or four-dimensional space-time. In particular, the curvature of space-time is directly related to the energy, momentum and stress of whatever is present, including matter and radiation.

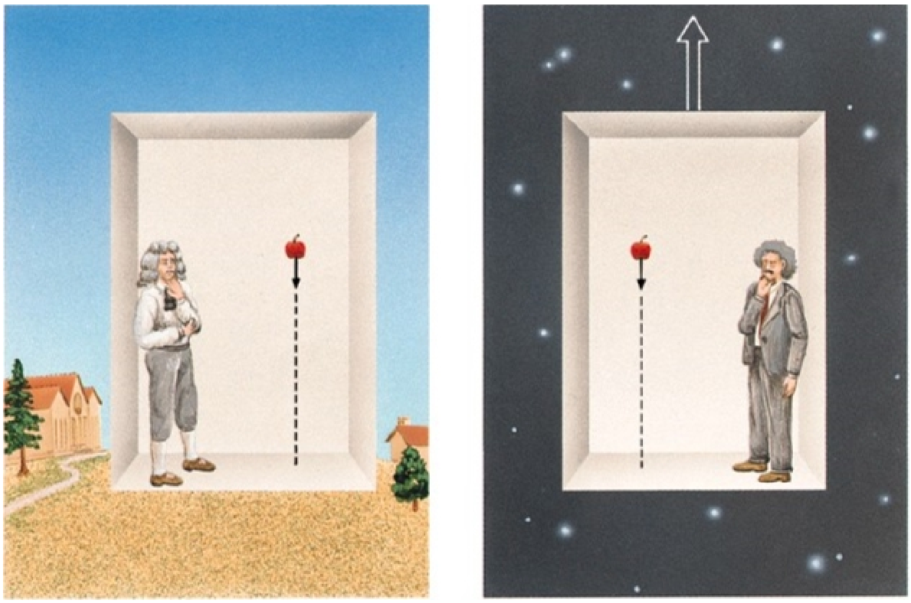
12.4.1 Assumptions and Principles

Albert Einstein and some others of his time believed in a physics that not to favour any frame system since that was in their eyes the reality of the Universe (we have already mentioned this point of view). But how can we subtract ourselves to the phenomenon of acceleration? The brilliant idea was to state the "equivalence postulate" below (which still in this early 121st century (holocene calendar) has not show any default by recent known experiences) plus the "invariance postulate" and "cosmological principle" we have already stated in the section of Special Relativity and the assumption that the motion of a particle that does not undergo any other interaction that gravitation follows a geodesic line (see below for the detailed proof).

12.4.1.1 Equivalence Postulates

At first, Albert Einstein will improve the equivalence postulate (also named "equivalence principle") whose older versions are due to Galileo and Newton:

Postulate: The (uniform!) acceleration of a mass (outside gravitational field) due to application of mechanical force and the acceleration of that mass subjected to a gravitational field are supposed completely equivalent. Thus, the results of mathematical analysis in one case may apply to the other (here this is already smart but consistent ... the idea is very good still had to have it...!).



In other words, the gravity field has a fundamental property which distinguishes it from all other fields known in nature: the free fall movement of bodies is universal, independent of the mass and composition of the bodies.

Corollary: The rest mass of a body must be the same whether it is measured in a frame within a gravitational field or outside a gravitational field (we speak then about "inertial mass" and of "gravitational mass" as we have already studied it in the section of Classical Mechanics at page 3087).

Remark

We must be careful and check that the corollary of the assumption of the equivalence principle is true otherwise all General Relativity would collapse (in the early 121st century (holocene calendar) experiments are trying to show a default to this principle)!

So all static and uniform gravitational field is equivalent to an accelerated frame in vacuum. We can consider any physical gravitational field as static and uniform in a relatively small region of space, and for a relatively short period of time to avoid the tides effects. We are thus led to state the "Weak Equivalence Principle" (WEF): For any event in space-time in an arbitrary gravitational field, we can choose a frame named "locally inertial frame" such as in the neighbourhood of the event of interest the free movement of all body (which are also in the gravity field!) is straight and uniform as we are able to apply the Lorentz transformations (see section Special Relativity page 5633). In other words, it is not possible to distinguish a system in vacuum space far away from any star (gravitational source) from as system falling in a constant homogeneous gravitational field.

If we experimentally show that WEF fails, then we have put into default the equivalence principle itself ... which has never been achieved in the laboratory to this date! For information the equivalence principle has even been confirmed at the quantum level (see [152]).

Remark

The concept of "locality" is very important because in reality we don't know any natural uniform gravitational field. For example, on Earth, two body distant of a certain length dropped from a certain height will fall to the ground with a shorter distance than the distance between them when they were released. This is what we name in physics the "tide effect": the gravitational field is never uniform (as far as we know...).

So the postulate of equivalence (which includes the principle of weak equivalence) finally asserts that the Newton's force on inertial mass m_i:

$$\vec{F}=m_i\vec{a} \tag{12.4.1}$$

and that of gravitation in the form of the Newton-Poisson law (see section Astronomy page 5267) with gravitational mass m_g:

$$\vec{F}_g=m_g\vec{g}=-m_g\vec{\nabla}\cdot\phi \tag{12.4.2}$$

are equivalent such as the inertial mass equals the gravitational mass and acceleration equal to gravity and that it is not possible to distinguish the both such that:

$$\begin{gathered} m_i = m_g \\ \updownarrow \\ \vec{a} = \vec{g} \end{gathered} \tag{12.4.3}$$

Remark

We must be careful and check that the corollary of the assumption of the equivalence principle is true otherwise all General Relativity would collapse! In this early 121st century - holocene calendar - experiments (like [482]) are still trying to find a default to this principle!

In what this postulate allows to resolve all the problems therefore? It's simple! The idea is the following:

When we will consider a body in acceleration, we first always equate it to the acceleration due to the fall in a gravitational field (by applying the postulate of equivalence). Then, we will assume, and will have to check (see proof further below) by rediscovering Newton's law, that acceleration due to the gravitational field is not due to the field itself but to the geometry of the deformed space by the presence of the mass (i.e. energy) that generates the gravitational field. Thus, the object is no longer in "free fall" but will be seen as sliding on the distorted spatial frame to acquire therefore its acceleration.

1. If the tensor calculus gives the possibility to express the laws of classical and relativistic mechanics in any coordinate system, it is then possible to see how the coordinate system (metric) acts on the expression of the laws of the Universe (Albert Einstein did not know that fact as he had not completed his calculations but had a presentiment about this)!
2. If the natural tensor expression of the laws of mechanics shows slippage (i.e. acceleration) on the spatial frame following the (local) considered metric, then the bet is won and then the acceleration can be seen as an effect whose cause is purely geometrical.

✍**Example:**

Suppose that two rockets, which we denoted by A and B are in a region of space away from any body. Their engines are stopped which physically results in a uniform motion. In each rocket, physicists are making mechanics experiments with objects which they know the inert mass. Suddenly the engine of the rocket A starts and communicates to it an acceleration whose effects felt inside the spaceship is an inertia force that constraint objects going to the floor. For physicists A rocket laws of mechanics are then the same as that observed in a gravitational field. They are logically led to interpret the force of inertia as the manifestation of a gravitational field. Using a balance, they can weigh their objects and assign to them a gravitational mass.

Suppose now that the physicists in rocket B could observe what happens in the rocket A. They know what their colleagues interpret as the weight of objects is in fact a force of inertia. The inertial force is proportional to the acceleration and the inertial mass. If the gravitational mass was different from the inertial mass the physicists of the rocket A could distinguish the effects of inertial forces from those of a gravitational field because the measured masses are distinct. We know that the inertial and gravitational mass are equivalent (Galilean principle of equivalence). It follows that the physicists of the rocket A have no way to differentiate between inertial forces resulting from an accelerated motion of their spaceship and the gravitational attraction forces.

However, we must temper the conclusions from this experience: the real gravitational fields differ from an accelerated frame since the gravitational acceleration varies with the distance to the main body while in an accelerated reference frame, the acceleration is the same at any point in space. However, locally, a gravitational field and an accelerated frame can not be differentiated!!!

We are led now to state the "Einstein's Equivalence Principle" (EEP) as did Albert Einstein: locally all the laws of physics are the same in a gravitational field and a uniformly accelerated frame.

This has a consequence: If the mass (which is equivalent to the energy as we have proved in the section of Special Relativity at page 5679) of an object is not differentiable that we are in a gravitational field or a uniformly accelerated frame that means that all types of energies (nuclear cohesion energy, electrostatic energy, proper gravitational energy of the object, etc.) of this object are indistinguishable. So the laws of Special Relativity are also valid whatever the considered frame and the principle of equivalence leads to two testable conclusions about the propagation of light. If the effects of gravitation and acceleration are indistinguishable, then rays of light should bend in a gravitational field. As well, light moving up through a gravitational field should be redshifted!

If the laws are not the same, then EEP (Einstein Equivalence Principle) is faulted, so verbatim WEF (weak equivalence principle) also and more globally the principle of equivalence in general but this has never happened experimentally as far as we know at this day.

✍**Example:**

By the WEF, it is interesting to note that the gravitational field also acts on the gravitational potential energy of the other bodies. We say then that the gravitational field is a "coupled field".

Caution! It turns out that in General Relativity, it's very hard to make the notion of "gravitational potential energy" precise. For example, you can't talk about the gravitational potential energy density at a point, because you can always go into a freely falling frame there, where the observed gravitational field is zero. For this reason, relativity textbooks generally say that the gravitational potential energy is not defined at all; instead energy (defined as not including this extra ill-defined piece) simply isn't conserved in General Relativity. If the reader may think this is unacceptable, remember that the only reason we elevated conservation of energy to an important principle in the 119th century (holocene calendar) was that it was observed to work in everyday situations. We never tested it in exotic situations like those with curved space-time, so there's no reason to expect the principle to continue to hold up (but many textbooks on General Relativity do so and we will also do it later ourselves...). At a deeper level, Noether's theorem tells us that energy conservation is related to time translation invariance (i.e. «our system will work the same if we start it at some other time» to not be confused with time reflection symmetry where «our system will work the same if we run it backwards»), and we don't have that in an expanding universe (indeed the energy carried by radiation decreases as the universe expands since every photon's wavelength increases).

Given that in General Relativity, the gravitational field is supposed to be described by the metric $g_{\mu\nu}$ (from which the 4-dimensional differentiable manifold that is space-time is supposed to be made), we can see a locally inertial frame as a coordinate system of space-time in which the metric becomes flat (pseudo-Riemannian):

$$g_{\mu\nu} \cong \eta_{\mu\nu} \tag{12.4.4}$$

using the notation introduce in the section of Tensor Calculus.

Such a coordinate system will by hypothesis always exists, indicating the existence, for any gravitational field, of locally inertial frames!

However when the metric is not flat the coordinates are named "Riemann normal coordinates" and then describes a Riemann metric space (curved space) and itself depends in a non-trivial way of the coordinates system (see sections Tensor Calculus page 2092 and Non-euclidean Geometry page 2672).

12.4.1.2 Mach Principle

If the equivalence principle highlights the equality of inert and gravitational mass, it does not enlighten us about the nature of these two masses. Finally, what are the inert and gravitational mass?

The deep nature of the inert mass should inform us about the inertia itself. The inertia is manifested in a passive form - the principle of inertia - and an active form - the second Newton's law. In general, it expresses a universal behaviour of bodies to resist to the change of movement. But we know that inertial motion is relative, that is to say that there is no absolute referential frame. Is it the same with the accelerated movement? Consider, to illustrate this question, a rocket in which has taken place a physicist and let us carry two experiments:

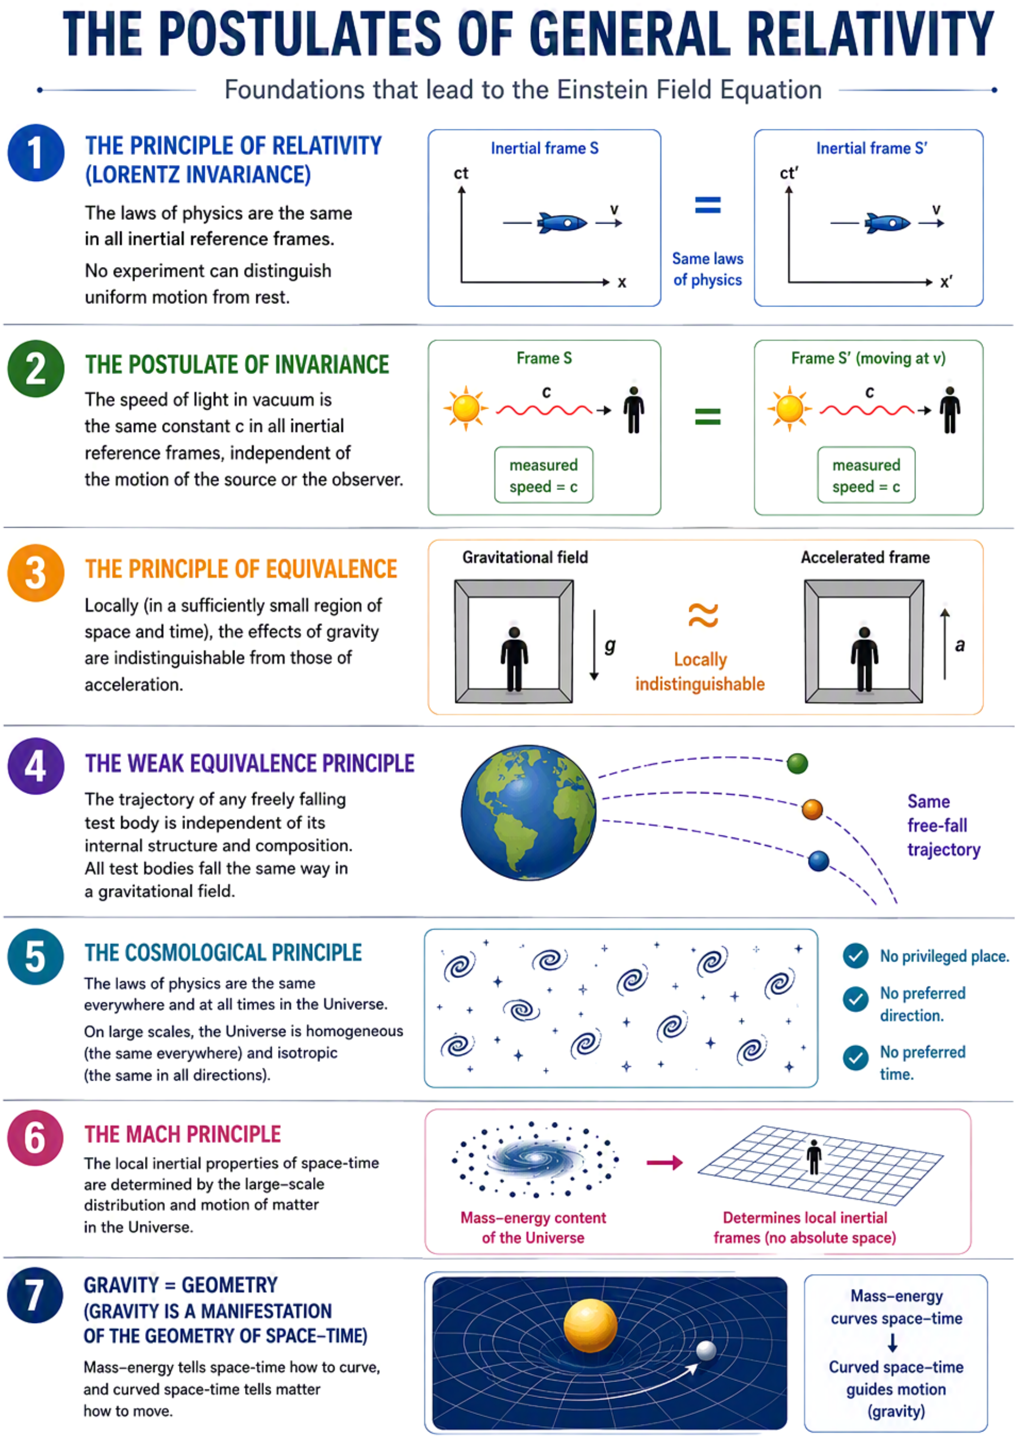
1. First experience: The rocket accelerates and the physicist is subjected to an inertial force oriented in the direction opposite to that of acceleration.
2. Second experience. Now assume that we gives to the whole Universe - at the exception of the rocket that moves in an inertial motion - an acceleration exactly opposite to the one of the rocket of the preceding experiment.

If the accelerated motion is relative then, for an observer, it is not possible to distinguish the two experiments. In particular, the physicist located inside the rocket must observe the emergence of an inertial force absolutely identical to the one he noted in the first experiment. The inert mass could then has its origin in the interactions of the gravitational mass of bodies with all the gravitational mass of the Universe! It is as if by moving all masses of the Universe, they dragged with them the objects in the rocket, the physicist therefore experienced a force that pulls in the same direction as the acceleration applied to stars.

Following Ernst Mach, physicist and philosopher of the 119th century (holocene calendar), the movement whatsoever inertial or accelerated, is relative.

This theory was named by Albert Einstein "Mach principle". At this date, Mach's principle has not been confirmed, but nor rejected! It is true that its experimental verification far exceeds our actual human capacities!

So if we add up in an infography the above postulates plus those of Special Relativity, we get:



THE POSTULATES OF GENERAL RELATIVITY

Foundations that lead to the Einstein Field Equation

1 THE PRINCIPLE OF RELATIVITY (LORENTZ INVARIANCE)

The laws of physics are the same in all inertial reference frames.

No experiment can distinguish uniform motion from rest.

Inertial frame S
ct
v
x
=
Same laws of physics
Inertial frame S′
ct′
v
x′

2 THE POSTULATE OF INVARIANCE

The speed of light in vacuum is the same constant c in all inertial reference frames, independent of the motion of the source or the observer.

Frame S
c
measured speed = c
=
Frame S′ (moving at v)
c
measured speed = c

3 THE PRINCIPLE OF EQUIVALENCE

Locally (in a sufficiently small region of space and time), the effects of gravity are indistinguishable from those of acceleration.

Gravitational field
g
≈
Locally indistinguishable
Accelerated frame
a

4 THE WEAK EQUIVALENCE PRINCIPLE

The trajectory of any freely falling test body is independent of its internal structure and composition. All test bodies fall the same way in a gravitational field.

Same free-fall trajectory

5 THE COSMOLOGICAL PRINCIPLE

The laws of physics are the same everywhere and at all times in the Universe.

On large scales, the Universe is homogeneous (the same everywhere) and isotropic (the same in all directions).

✓ No privileged place.
✓ No preferred direction.
✓ No preferred time.

6 THE MACH PRINCIPLE

The local inertial properties of space-time are determined by the large–scale distribution and motion of matter in the Universe.

Mass–energy content of the Universe
Determines local inertial frames (no absolute space)

7 GRAVITY = GEOMETRY (GRAVITY IS A MANIFESTATION OF THE GEOMETRY OF SPACE–TIME)

Mass–energy tells space-time how to curve, and curved space-time tells matter how to move.

Mass–energy curves space–time
↓
Curved space–time guides motion (gravity)

Figure 12.218: **Summary of the postulates of General Relativity**

12.4.2 Metrics

Albert Einstein assumed that gravity was only the manifestation of space-time distortions (see [13]). To try to illustrate in the more possible simple and illustrated way the idea of Albert Einstein, consider a rolling gear at constant speed (say, one tooth at a second) on a rack. Imagine that we have the power to simultaneously change the pitch of the rack and the wheel when and where we wish. Let us do things such that the pitch of the rack slightly increases from one tooth to another. For fixed observers the gear is then driven with a uniformly accelerated motion as, in effect, at each turn thereof always travels a greater distance. On the other hand, if one chooses the rack as a reference and thereof the pitch as a standard to measure the movement of the wheel is then uniform (one tooth per second). The acceleration of the wheel is the consequence of the increase in the pitch of the rack.

Let us continue the analogy: the pitch of the rack acts as a local measurement standard in our one-dimensional space that represents the rack. In geometry, it is named the "metric". The metric is what determines the distance between two points, it is somehow the standard infinitesimal space unit. In Euclidean geometry, the metric is constant, allowing us to define universal measurement standards. Bernhard Riemann, for example, invented a metric geometry which can vary from one point to another in space, which allowed him to describe curved spaces like the surface of a sphere, for example (see section Non-Euclidean Geometry page 2663).

During our study of Tensor Calculus, Non-Euclidean Geometries and Differential Geometry (section that the reading is more than recommended!!!) we have seen that the measurement of the curvilinear distance ds between two points positioned in a two or three dimensions space can be made using a large number of coordinate system by the "metric equation" (see section Special Relativity page 5704 and section of Non-Euclidean Geometry page 2669):

$$\mathrm{d}s^2=\mathrm{d}x_\nu \mathrm{d}x^\mu=g_{\mu\nu}\mathrm{d}x^\mu \mathrm{d}x^\nu \tag{12.4.5}$$

In General Relativity, the idea is to make the theoretical model independent of the background and thus build it in a covariant form (which some physicists liken to assimilate to a postulate named the "covariance principle"). An excellent candidate for this type of approach is to use the tensor formalism. This is the reason why the metric equation is therefore one of the pillars.

✍**Examples:**

E1. Rectangular coordinates (in $\mathbb{R}^3$):

$$\boxed{\mathrm{d}s^2=\mathrm{d}x^2+\mathrm{d}y^2+\mathrm{d}z^2} \tag{12.4.6}$$

If the squared distance satisfies this relation then we are in a flat space or at least locally flat (see section Non-Euclidean Geometry page 2669).

E2. Polar coordinates (in $\mathbb{R}^2$):

$$\begin{aligned}x=r\cos(\phi)&\Rightarrow \mathrm{d}x=\mathrm{d}r\cos(\phi)-r\sin(\phi)\mathrm{d}\phi\\ y=r\sin(\phi)&\Rightarrow \mathrm{d}x=\mathrm{d}r\sin(\phi)+r\cos(\phi)\mathrm{d}\phi\end{aligned} \tag{12.4.7}$$

Therefore:

$$\begin{aligned}\mathrm{d}s^2&=\mathrm{d}x^2+\mathrm{d}y^2=(\mathrm{d}r\cos(\phi)-r\sin(\phi)\mathrm{d}\phi)^2+(\mathrm{d}r\sin(\phi)+r\cos(\phi)\mathrm{d}\phi)^2\\&=\mathrm{d}r^2\cos^2(\phi)-\cancel{2r\mathrm{d}r\sin(\phi)\cos(\phi)\mathrm{d}\phi}+r^2\sin^2(\phi)\mathrm{d}\phi^2+\mathrm{d}r^2\sin^2(\phi)\\&+\cancel{2r\mathrm{d}r\sin(\phi)\cos(\phi)\mathrm{d}\phi}+r^2\cos^2(\phi)\mathrm{d}\phi^2\\&=\mathrm{d}r^2(\cos^2(\phi)+\sin^2(\phi))+r^2(\cos^2(\phi)+\sin^2(\phi))\mathrm{d}\phi^2\end{aligned}\tag{12.4.8}$$

Therefore:

$$\boxed{\mathrm{d}s^2=\mathrm{d}r^2+r^2\mathrm{d}\phi^2}\tag{12.4.9}$$

If the squared distance satisfies this relation then we are in a flat space or at least locally flat (see section Non-Euclidean Geometry page 2669).

E3. Cylindrical coordinates (in $\mathbb{R}^3$):

$$\begin{aligned}x=r\cos(\phi)&\Rightarrow\mathrm{d}x=\mathrm{d}r\cos(\phi)-r\sin(\phi)\mathrm{d}\phi\\y=r\sin(\phi)&\Rightarrow\mathrm{d}x=\mathrm{d}r\sin(\phi)+r\cos(\phi)\mathrm{d}\phi\\z=z&\Rightarrow\mathrm{d}z=\mathrm{d}z\end{aligned}\tag{12.4.10}$$

when we put this into $\mathrm{d}s^2=\mathrm{d}x^2+\mathrm{d}y^2+\mathrm{d}z^2$ we get in a similar way as before:

$$\mathrm{d}s^2=\mathrm{d}r^2+r^2\mathrm{d}\phi^2+\mathrm{d}z^2\tag{12.4.11}$$

If the squared distance satisfies this relation then we are in a curved space (cylindrical type) but that may be locally flat (see section Non-Euclidean Geometry page 2669). In fact, to have the metric of the cylinder surface and not simply of the plane expressed in cylindrical coordinates, we must take the following metric:

$$\boxed{\mathrm{d}s^2=\mathrm{d}r^2+r^2\mathrm{d}\phi^2}\tag{12.4.12}$$

whose origin was proved in the section of Differential Geometry and also... just previously...

E4. Spherical coordinates (in $\mathbb{R}^3$) for which we have:

$$\begin{aligned}&x=r\sin(\theta)\cos(\phi)\Rightarrow\mathrm{d}x=\mathrm{d}r\sin(\theta)\cos(\phi)+r\cos(\theta)\mathrm{d}\theta\cos(\phi)-r\sin(\theta)\sin(\phi)\mathrm{d}\phi\\&y=r\sin(\theta)\sin(\phi)\Rightarrow\mathrm{d}x=\mathrm{d}r\sin(\theta)\sin(\phi)+r\cos(\theta)\mathrm{d}\theta\sin(\phi)+r\sin(\theta)\cos(\phi)\mathrm{d}\phi\\&z=r\cos(\theta)\Rightarrow\mathrm{d}z=\mathrm{d}r\cos(\theta)-r\sin(\theta)\mathrm{d}\theta\end{aligned}\tag{12.4.13}$$

when we put this into $\mathrm{d}s^2=\mathrm{d}x^2+\mathrm{d}y^2+\mathrm{d}z^2$ we get:

$$\begin{aligned}\mathrm{d}s^2=&(\mathrm{d}r\sin(\theta)\cos(\phi)+r\cos(\theta)\mathrm{d}\theta\cos(\phi)-r\sin(\theta)\sin(\phi)\mathrm{d}\phi)^2\\&+(\mathrm{d}r\sin(\theta)\sin(\phi)+r\cos(\theta)\mathrm{d}\theta\sin(\phi)+r\sin(\theta)\cos(\phi)\mathrm{d}\phi)^2\\&+(\mathrm{d}r\cos(\theta)-r\sin(\theta)\mathrm{d}\theta)^2\end{aligned}\tag{12.4.14}$$

Now remember that (see section Algebra Calculus page 1361):

$$\begin{aligned}(a+b-c)^2&=a^2+b^2+c^2+2(ab-ac-bc)\\(a+b+c)^2&=a^2+b^2+c^2+2(ab+ac+bc)\\(a-b)^2&=a^2-2ab-b^2\end{aligned}\qquad(12.4.15)$$

Therefore:

$$\begin{aligned}\mathrm{d}s^2=&\,\mathrm{d}r^2\sin^2(\theta)\cos^2(\phi)+r^2\cos^2(\theta)\mathrm{d}\theta^2\cos^2(\phi)+r^2\sin^2(\theta)\sin^2(\phi)\mathrm{d}\phi^2\\&+2(r\mathrm{d}r\mathrm{d}\theta\cos(\theta)\sin(\theta)\cos^2(\phi)-r\mathrm{d}r\mathrm{d}\phi\sin^2(\theta)\cos(\phi)\sin(\phi)\\&-r^2\mathrm{d}\theta\mathrm{d}\pi\cos(\theta)\sin(\theta)\cos(\phi)\sin(\phi)\\&+\mathrm{d}r^2\sin^2(\theta)\sin^2(\phi)+r^2\cos^2(\theta)\mathrm{d}\theta^2\sin^2(\phi)+r^2\sin^2(\theta)\cos^2(\phi)\mathrm{d}\phi^2\\&+2(r\mathrm{d}r\mathrm{d}\theta\sin(\theta)\cos(\theta)\sin^2(\phi)+r\mathrm{d}r\mathrm{d}\phi\sin^2(\theta)\sin(\phi)\cos(\phi)\\&+r^2\mathrm{d}\theta\mathrm{d}\phi\cos(\theta)\sin(\theta)\sin(\phi)\cos(\phi)\\&+\mathrm{d}r^2\cos^2(\theta)-2r\mathrm{d}r\mathrm{d}\theta\cos(\theta)\sin(\theta)+r^2\sin^2(\theta)\mathrm{d}\theta^2\end{aligned}\qquad(12.4.16)$$

After a first set of factorization and basic simplifications of identical terms, we get:

$$\mathrm{d}s^2=\mathrm{d}r^2+r^2\mathrm{d}\theta^2+r^2\sin^2(\theta)\mathrm{d}\phi^2\qquad(12.4.17)$$

If the squared distance satisfies this relation then we are in a curved space (spherical type) but that locally may be flat (see section Non-Euclidean Geometry page 2669). In fact, for the metric of the surface of the sphere and not simply of the plane expressed in spherical coordinates, we have to take the following metric:

$$\boxed{\mathrm{d}s^2=r^2\mathrm{d}\theta^2+r^2\sin^2(\theta)\mathrm{d}\phi^2}\qquad(12.4.18)$$

whose origin has been proved in the section of Differential Geometry (see page 2884). We also checked in the section of Tensor Calculus, that the Ricci curvature of the spherical prior-previous metric was zero (see page 2127). By cons, we had right after checked that if we took the previous metric of the surface of the sphere, the Ricci curvature was not zero (and it is still happy!).

Until then, you may be wondering where we are going? In fact, we try to define from these relations, a mathematical being that consistent with the Einstein's hypothesis, expresses the geometric properties of given space.

How we will do this?: We first simply change the notations. Instead of using the symbols (x,y,z,θ,ϕ,r) we will write $x^1,x^2,x^3,\ldots$.

Caution! The numbers suffixes are not powers!!! These are dummy values that are only there to symbolize the x-th coordinate of a given basis.

Now let us write again our metric equations with this new notation by considering it is only specific examples that do not necessarily have relevant physical sense (we also mentioned it earlier!):

- Rectangular coordinates:

$$\mathrm{d}s^2=(\mathrm{d}x^1)^2+(\mathrm{d}x^2)^2+(\mathrm{d}x^3)^2 \tag{12.4.19}$$

- Polar coordinates:

$$\mathrm{d}s^2=(\mathrm{d}x^1)^2+(x^1)^2(\mathrm{d}x^2)^2 \tag{12.4.20}$$

- Cylindrical coordinates:

$$\mathrm{d}s^2=(\mathrm{d}x^1)^2+(x^1)^2(\mathrm{d}x^2)^2+(\mathrm{d}x^3)^2 \tag{12.4.21}$$

- Spherical coordinates:

$$\mathrm{d}s^2=(\mathrm{d}x^1)^2+(x^1)^2(\mathrm{d}x^2)^2+(x^1)^2\sin^2(x^2)(\mathrm{d}x^3)^2 \tag{12.4.22}$$

Now let us recall again that the "metric tensor" (so named because it calibrates space-time) denoted :

$$g_{\mu\nu}=\begin{bmatrix} g_{11} & g_{12} & g_{13}\\ g_{21} & g_{22} & g_{23}\\ g_{31} & g_{32} & g_{33}\end{bmatrix} \tag{12.4.23}$$

is involved in the metric equation as follows in the Lorentz invariant (see section Special Relativity page 5704):

$$\mathrm{d}s^2=\mathrm{d}x_\mu\mathrm{d}x^\nu=g_{\mu\nu}\mathrm{d}x^\mu\mathrm{d}x^\nu \tag{12.4.24}$$

and notice that the components of the matrix are also dimensionless!

This mathematical entity which is a tensor thus contains the parameters of the curvature (we also sometimes say of the "stress" or "tension") wherein a space is located. But then what contains the metric tensor of space-time for a flat Euclidean space?

According to the summing writing Einstein's convention (see section Tensor Calculus page 2044), for example, for $\mu=\nu=2$ we have:

$$\mathrm{d}s^2=g_{\mu\nu}\mathrm{d}x^m\mathrm{d}x^n=g_{11}\mathrm{d}x^1\mathrm{d}x^1+g_{12}\mathrm{d}x^1\mathrm{d}x^2+g_{21}\mathrm{d}x^2\mathrm{d}x^1+g_{22}\mathrm{d}x^2\mathrm{d}^2x \tag{12.4.25}$$

So if we return to our tensor for the flat Euclidean space, we already know (see section Vector Calculus page 1810) that m and n goes from 1 to 3 and we have in our tensor $g_{\mu\nu}=0$ for $\mu\neq\nu$ and $g_{\mu\nu}=1$ for $\mu=\nu$ (symmetrical tensor). So:

$$\begin{aligned}\mathrm{d}s^2&=g_{\mu\nu}\mathrm{d}x^\mu\mathrm{d}x^\nu=g_{11}\mathrm{d}x^1\mathrm{d}x^1+g_{22}\mathrm{d}x^2\mathrm{d}x^2+g_{33}\mathrm{d}x^3\mathrm{d}x^3\\&=1\cdot(\mathrm{d}x^1)^2+1\cdot(\mathrm{d}x^2)^2+1\cdot(\mathrm{d}x^3)^2=(\mathrm{d}x^1)^2+(\mathrm{d}x^2)^2+(\mathrm{d}x^3)^2\end{aligned} \tag{12.4.26}$$

Therefore:

$$g_{\mu\nu}=\begin{bmatrix}1&0&0\\0&1&0\\0&0&1\end{bmatrix} \tag{12.4.27}$$

which as usual in this textbook we make usage of the abusive notation (already indicated in the section of Tensor Calculus) to not put $g_{\mu\nu}$ (since a tensor and its matrix form are normally two separate things strictly speaking).

This result is remarkable, because the metric tensor will therefore enable us to define the properties of a space from a simple mathematical being that can easily be handled formally as we already seen in the section of Tensor Calculus, Non-Euclidean Geometry and Differential Geometry.

In polar coordinates the tensor $g_{\mu\nu}$ is:

$$g_{\mu\nu}(r,\phi)=\begin{bmatrix} x_{11} & x_{12} \\ x_{21} & x_{22} \end{bmatrix}=\begin{bmatrix} 1 & 0 \\ 0 & (x^1)^2 \end{bmatrix}=\begin{bmatrix} 1 & 0 \\ 0 & r^2 \end{bmatrix} \tag{12.4.28}$$

Check:

$$\mathrm{d}s^2=g_{\mu\nu}\mathrm{d}x^\mu\mathrm{d}x^\nu=g_{11}\mathrm{d}x^1x^1+g_{22}\mathrm{d}x^2\mathrm{d}x^2=(\mathrm{d}x^1)^2+(x^1)^2(\mathrm{d}x^2)^2 \tag{12.4.29}$$

And in cylindrical coordinates the tensor $g_{\mu\nu}$ is written:

$$g_{\mu\nu}(r,\phi,z)=\begin{bmatrix} x_{11} & x_{12} & x_{13} \\ x_{21} & x_{22} & x_{23} \\ x_{31} & x_{32} & x_{33} \end{bmatrix}=\begin{bmatrix} 1 & 0 & 0 \\ 0 & (x^1)^2 & 0 \\ 0 & 0 & 1 \end{bmatrix}=\begin{bmatrix} 1 & 0 & 0 \\ 0 & r^2 & 0 \\ 0 & 0 & 1 \end{bmatrix} \tag{12.4.30}$$

We will not do the check as the result is obvious (excepted on reader request).

In spherical coordinates the tensor $g_{\mu\nu}$ is a little more complex and is written:

$$g_{\mu\nu}(r,\theta,\varphi)=\begin{bmatrix} x_{11} & x_{12} & x_{13} \\ x_{21} & x_{22} & x_{23} \\ x_{31} & x_{32} & x_{33} \end{bmatrix}=\begin{bmatrix} 1 & 0 & 0 \\ 0 & (x^1)^2 & 0 \\ 0 & 0 & (x_1\sin(x^2))^2 \end{bmatrix}=\begin{bmatrix} 1 & 0 & 0 \\ 0 & r^2 & 0 \\ 0 & 0 & r^2\sin^2(\theta) \end{bmatrix} \tag{12.4.31}$$

We will also not do the check as the result is obvious (excepted as always on reader request).

Remark

As we have already mentioned it, in the section of Tensor Calculus at page 2121, we have $g^{ij}=(g_{ij})^{-1}$ and the reader can quickly check this with Maple™ 4.00b as inverting a matrix is always a boring manual work (here the code is given only for the spherical coordinates but the idea is the same for the others):

```
>with(linalg):
>A:=array([[1,0,0],[0,r^2,0],[0,0,r^2*sin(theta)^2]]);
>inverse(A);
```

In Special Relativity, we have seen that the notions of space and time were implicitly bounded. Thus, to study modern physics (this does not really interest the pure mathematician), we need to add to our metric tensor a time component to get what we name the "space-time metric tensor".

To determine the writing of this tensor, we will place us at first in a Minkowski space where we have for recall (see section Special Relativity page 5705):

$$\mathrm{d}s^2=c^2\mathrm{d}t^2-(\mathrm{d}x^2+\mathrm{d}y^2+\mathrm{d}z^2) \tag{12.4.32}$$

which is the infinitesimal interval of space-time between two infinitely close events (or considered as it at a given scale...) named as we know the "interval invariant".

Thus by putting:

$$x^0 = ct, x^1 = x, x^2 = y, x^3 = z \tag{12.4.33}$$

We have:

$$\boxed{g_{\mu\nu} = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & -1 & 0 & 0 \\ 0 & 0 & -1 & 0 \\ 0 & 0 & 0 & -1 \end{bmatrix}} \tag{12.4.34}$$

with the "signature":

$$\text{sign}(g_{\mu\nu}) = (1, -1, -1, -1) = (+, -, -, -) \tag{12.4.35}$$

Remark

For all metric tensor that we have determined before, if we express them in space-time (thus adding time component), the spatial components will all have a negative sign!

The choice of the system of coordinates with which we describe space-time is named a "space-time gauge". If a quantity is unchanged under a space-time gauge transformation, it is say to be as we already know after our study of Quantum Physics "gauge invariant".

We will derive later other metrics that are much less intuitive (like the Schwarzschild metric, the Friedmann–Lemaître–Robertson–Walker metric, the Kerr metric, the De Sitter/anti-De Sitter metrics, the Alcubierre metric and so on...) once we will have proved far later below the Einstein's fields equation.

There is an excellent booklet of 89 pages containing an exhaustive list of 24 metrics (however the Melvin magnetic universe metric is missing) with their respective Christoffel symbols named *Catalogue of Space-times* (see [402]). Here are some of the metrics contained in this booklet:

Name of metric	**Expression**
Minkowski	$\mathrm{d}s^2 = -c^2\mathrm{d}t^2 + \mathrm{d}x^2 + \mathrm{d}y^2 + \mathrm{d}z^2$
Schwarzschild	$\mathrm{d}s^2 = -\left(1 - \frac{r_s}{r}\right) c^2\mathrm{d}t^2 + \frac{1}{1 - r_s/r} dr^2 + r^2 \left(\mathrm{d}\vartheta^2 + \sin^2(\vartheta)\mathrm{d}\varphi^2\right)$ $r_s = 2GM/c^2$
Friedman-Robertson-Walker	$\mathrm{d}s^2 = -c^2\mathrm{d}t^2 + R^2 \left\{\frac{\mathrm{d}\eta^2}{1-k\eta^2} + \eta^2 \left(\mathrm{d}\vartheta^2 + \sin^2(\vartheta)\mathrm{d}\varphi^2\right)\right\}$
Alcubierre	$-c^2\mathrm{d}t^2 + \left(\mathrm{d}x - \frac{\mathrm{d}x_s(t)}{\mathrm{d}t} f\left(r_s\right)\mathrm{d}t\right)^2 + \mathrm{d}y^2 + \mathrm{d}z^2$ $v_s = \frac{\mathrm{d}x_s(t)}{\mathrm{d}t}$ $r_s(t) = \sqrt{(x - x_s(t))^2 + y^2 + z^2}$ $f\left(r_s\right) = \frac{\tanh\left(\sigma\left(r_s + R\right)\right) - \tanh\left(\sigma\left(r_s - R\right)\right)}{2\tanh(\sigma R)}$
Barriola-Vilenkin	$\mathrm{d}s^2 = -c^2\mathrm{d}t^2 + \mathrm{d}r^2 + k^2r^2 \left(\mathrm{d}\vartheta^2 + \sin^2(\vartheta)\mathrm{d}\varphi^2\right)$
Bertotti-Kasner	$\mathrm{d}s^2 = -c^2\mathrm{d}t^2 + e^{2\sqrt{\Lambda}ct}\mathrm{d}r^2 + \frac{1}{\Lambda}\left(\mathrm{d}\vartheta^2 + \sin^2(\vartheta)\mathrm{d}\varphi^2\right)$ $\Lambda > 0$
Cosmic string	$\mathrm{d}s^2 = e^{-2U}\left[e^{2K}\left(\mathrm{d}\rho^2 - \mathrm{d}t^2\right) + \rho^2\mathrm{d}\varphi^2\right] + e^{2U}\mathrm{d}z^2$ $U = CJ_0(\rho)\cos(t)$ $K := \frac{1}{2}C^2\rho\left\{\rho\left[J_0(\rho)^2 + J_1(\rho)^2\right] - 2J_0(\rho)J_1(\rho)\cos^2(t)\right\}$ $J_n(x) = \sum_{m=0}^{+\infty}\frac{(-1)^m}{\Gamma(m+1)\Gamma(m+n+1)}\left(\frac{x}{2}\right)^{2m+n}$
Bessel	$\mathrm{d}s^2 = -\left(1 - \frac{r_s}{r}\right) c^2\mathrm{d}t^2 + \frac{1}{1 - r_s/r}\mathrm{d}r^2 + r^2\left(\mathrm{d}\vartheta^2 + \beta^2\sin^2(\vartheta)\mathrm{d}\varphi^2\right)$ $r_s = 2GM/c^2$
Ernst	$\mathrm{d}s^2 = \Lambda^2\left[-\left(1 - \frac{2M}{r}\right)\mathrm{d}t^2 + \frac{\mathrm{d}r^2}{1 - 2M/r} + r^2\mathrm{d}\vartheta^2\right] + \frac{r^2\sin^2(\vartheta)}{\Lambda^2}\mathrm{d}\varphi^2$ $\Lambda = 1 + B^2r^2\sin^2(\vartheta)$
Gödel	$\mathrm{d}s^2 = -c^2\mathrm{d}t^2 + \frac{\mathrm{d}r^2}{1 + [r/(2a)]^2} + r^2\left[1 - \left(\frac{r}{2a}\right)^2\right]\mathrm{d}\varphi^2 + \mathrm{d}z^2 - 2r^2\frac{c}{\sqrt{2}a}\mathrm{d}t\mathrm{d}\varphi$
Halilsoy	$\mathrm{d}s^2 = V\left[e^{2K}\left(\mathrm{d}\rho^2 - \mathrm{d}t^2\right) + \rho^2\mathrm{d}\varphi^2\right] + \frac{1}{V}(\mathrm{d}z + A\mathrm{d}\varphi)^2$ $V = \cosh^2(\alpha)e^{-2CJ_0(\rho)\cos(t)} + \sinh^2(\alpha)e^{2CJ_0(\rho)\cos(t)}$ $K = \frac{C^2}{2}\left[\rho^2\left(J_0(\rho)^2 + J_1(\rho)^2\right) - 2\rho J_0(\rho)J_1(\rho)\cos^2(t)\right]$ $J_n(x) = \sum_{m=0}^{+\infty}\frac{(-1)^m}{\Gamma(m+1)\Gamma(m+n+1)}\left(\frac{x}{2}\right)^{2m+n}$
Janis-Newman-Winicour	$\mathrm{d}s^2 = -\alpha^\gamma c^2\mathrm{d}t^2 + \alpha^{-\gamma}\mathrm{d}r^2 + r^2\alpha^{-\gamma+1}\left(\mathrm{d}\vartheta^2 + \sin^2(\vartheta)\mathrm{d}\varphi^2\right)$ $\alpha = 1 - r_s/(\gamma r)$ $r_s = 2GM/c^2$
Kasner	$\mathrm{d}s^2 = -c^2\mathrm{d}t^2 + t^{2p_1}\mathrm{d}x^2 + t^{2p_2}\mathrm{d}y^2 + t^{2p_3}tz^2$ $p_1 + p_2 + p_3 = 1$ $p_1^2 + p_2^2 + p_3^2 = 1$
Kerr	$\mathrm{d}s^2 = -\left(1 - \frac{r_sr}{\Sigma}\right)c^2\mathrm{d}t^2 - \frac{2r_sar\sin^2(\vartheta)}{\Sigma}c\mathrm{d}t\mathrm{d}\varphi + \frac{\Sigma}{\Delta}\mathrm{d}r^2 + \Sigma\mathrm{d}\vartheta^2$ $+\left(r^2 + a^2 + \frac{r_sa^2r\sin^2(\vartheta)}{\Sigma}\right)\sin^2(\vartheta)\mathrm{d}\varphi^2$ $\Sigma = r^2 + a^2\cos^2(\vartheta)$ $\Delta = r^2 - r_sr + a^2$ $r_s = 2GM/c^2$
...	...

Table 12.22: **Some famous metrics (source: Catalogue of Space-times [402])**

Most of these metrics were not derived. They are just written down and then their properties are analysed. Sometimes it is named an "ansatz", which is basically just an educated guess that we make and then work backwards to show that the guess was good (there is a very good example of such an intellectual process in [208]).

12.4.2.1 Schild Criteria (Einstein redshift effect Newtonian approach)

We will prove later that gravitation as formulated in Newtonian mechanics is completely describable by a curvature formulation of space-time. But first we want to introduce to the reader with, in our point of view, the easiest development that can be done without General Relativity to compare it also later with the easiest development that can be done with General Relativity (see page 5796) the gravitational redshift effect!

Imagine first a very height tower of height h built on the surface of the Earth. A man sits at the ground of the tower, and sends a signal of pulsation ω_A to a colleague B at the top of the tower. There will be, and we will immediately prove it, that the pulsation ω_B of the wave received by B differs of ω_A according to the relation:

$$\frac{\omega_A}{\omega_B}=1+\frac{gh}{c^2} \tag{12.4.36}$$

Hence:

$$\Delta\omega=\omega_A-\omega_B>0 \tag{12.4.37}$$

This shift of pulsation (frequencies respectively) in a gravitational field is what we name the "Einstein's effect", or "gravitational redshift".

We will first prove this relation using conventional arguments and now well known to us. Later we will prove that in fact this is only an approximation of a result that we will get later using General Relativity curvature properties.

A material body sent from the ground to the sky must fight against the gravitational force that pulls[43] it down. So it will lose a certain amount of energy, equivalent to gravitational potential energy gained during the trip. The total energy E_A of the body at the ground level is therefore its mass energy (see section Special Relativity page 5679) to which we add the potential energy at the height of the tower:

$$E_A=mc^2+mgh \tag{12.4.38}$$

The energy of this body when you reach the top of the tower is simply its mass energy:

$$E_B=mc^2 \tag{12.4.39}$$

because he had to spend the energy mgh during the trip to go up. The ratio of energy is then:

$$\frac{E_A}{E_B}=\frac{mc^2+mgh}{mc^2}=1+\frac{gh}{c^2} \tag{12.4.40}$$

---

[43] Keep in mind that's in the framework of the Newtonian model of gravity as we that in General Relativity there are no "pull".

This ratio being independent of the mass m, we can take the limit $m \to 0$ in order to have the relation for the photon. We then get:

$$\frac{E_A}{E_B}=\frac{\hbar\omega_A}{\hbar\omega_B}=\frac{\omega_A}{\omega_B}=\frac{f_A}{f_B}=\frac{T_B}{T_A}=1+\frac{gh}{c^2} \tag{12.4.41}$$

which implies:

$$T_B > T_A \tag{12.4.42}$$

That is to say the clocks run slower in a gravitational field as seen by a distant observer!

We will now study this phenomenon in the context of the Minkowski space-time. We will see then a contradiction, what will motivate the transition to a curved space-time: this is the argument of a curved geometry that was used by Schild.

Let us consider again the human experience of a human in A which sends a wave to his friend positioned in B. Given Δt_A the time taken by A to emit exactly 1 cycle of the wave (see section Wave Mechanics page 3480):

$$\Delta t_A=\frac{\lambda_A}{c}=\frac{1}{\omega_A c} \tag{12.4.43}$$

and Δt_B the time taken for B to receive this cycle:

$$\Delta t_A=\frac{\lambda_B}{c}=\frac{1}{\omega_B c} \tag{12.4.44}$$

Because of the Einstein's effect just seen previously, we know that $\omega_A > \omega_B$ and therefore that $\Delta t_A < \Delta t_B$ in proper time! That is to say that time passes more slowly for someone on the ground (A) than another person in a mountain top (B)!

But as we are in flat geometry and the gravitational field is assumed static, we deduce that space-time trajectories described by the signals must be parallel! This leads to the conclusion that the proper time interval would be $\Delta t_A = \Delta t_B$ (according to Special Relativity).

If we opt for a curved space, we can preserve the relation $\Delta t_A < \Delta_B$, that is to say that time passes more slowly for A than for B. This simply results in the fact that in curved geometry, the proper time (!) of an observer depends on the metric.

Let us now notice that same developments can be made by assimilating the previous experience with a train that moves with constant acceleration g (horizontal situation of the previous one!). The observer A is in the rear compartment (equivalent to the floor of the Earth in the preceding experiment) sends a wave to his colleague B on the front of the train (at a distance h).

The observer B receives the wave after a time $\Delta t = h/c$. During this time, the train has accelerated, and its speed has increased of a value $\Delta v = g\Delta t = gh/c$. Therefore, the wave seen by B will be altered by the conventional Doppler effect (see section Music Mathematics page 8212):

$$\frac{\Delta\lambda}{\lambda_A}=\frac{\Delta v\Delta t}{c\Delta t}=\frac{\Delta v}{c}=\frac{gh}{c^2} \tag{12.4.45}$$

We fall back on the initial results of the Einstein's effect by simply writing:

$$z:=\frac{\Delta\lambda}{\lambda_A}=\frac{\lambda_B-\lambda_A}{\lambda_A}=\frac{\lambda_B}{\lambda_A}-1=\frac{\omega_B}{\omega_A}-1 \tag{12.4.46}$$

giving gloriously:

$$\left.\begin{matrix}\dfrac{\Delta\lambda}{\lambda_A}=\dfrac{gh}{c^2}\\ \dfrac{\Delta\lambda}{\lambda_A}=\dfrac{\omega_B}{\omega_A}-1\end{matrix}\right\}:\frac{\omega_B}{\omega_A}=1+\frac{gh}{c^2} \tag{12.4.47}$$

We find more often this relation in the form below in the literature using the relation between pulsation and frequency and Newton's gravitational force to explicit g:

$$\frac{\omega_B}{\omega_A}=1+\frac{GMh}{r^2c^2} \tag{12.4.48}$$

and putting h as being equal to r:

$$\boxed{\frac{\omega_B}{\omega_A}=1+\frac{GM}{rc^2}=1+\varphi} \tag{12.4.49}$$

and after rearranging we also found sometimes in textbooks:

$$\frac{f_B-f_A}{f_A}=\frac{GM}{rc^2} \tag{12.4.50}$$

or even more frequently:

We also find this last relation in the following condensed form:

$$\frac{\Delta f}{f_0}=\frac{\Delta\lambda}{\lambda_0}=\frac{a_g}{c^2} \tag{12.4.51}$$

The same result can be obtained using the Schwarzschild metric (see further below), hence the name of this effect that can also be obtained from the mathematical tools of Einstein's General Relativity. We will prove later, in a simple way, using this metric that time actually flows more slowly in a gravitational field (assumption we made a few paragraphs above).

We see that in all cases:

$$f_B>f_A \tag{12.4.52}$$

since the right term is positive and not zero. This simply means that the electromagnetic wave in analogy to the color spectrum shifts toward red. Thus, Einstein's effect is indeed a gravitational redshift!

The frequency difference is very small and therefore difficult to measure even with the best spectroscopes. The slightest disturbance can completely mask the Einstein's effect. It will be necessary to wait until 11960 (holocene calendar) that the experience of Robert Pound and his graduate student Glen A. Rebka Jr. to be capable of measuring a frequency offset with an accuracy of 1% therefore leaving no doubt as to the reality of this phenomenon.

12.4.3 Equations of movement

We will prove here that the equation of motion of a free particle is constant along its world line by first limiting ourselves to the case of a flat space (Minkowski space type). Then we will generalize this result in any kind of space using a simple development, to show quite clearly that the equation of motion is independent of the mass and follows the curvature of space !!! Finally, we will present a second proof in any kind of space using the variational principle.

So let us start by proving the equation of motion of a free particle in a flat space.

During our study of Special Relativity, we proved that the Relativistic Lagrangian of a free particle was given by (see section Special Relativity page 5683):

$$L=-m_0c^2\sqrt{1-\frac{v^2}{c^2}} \tag{12.4.53}$$

and for this we started from the action (hypothetical):

$$S_0=-m_0c^2\int \mathrm{d}t' \tag{12.4.54}$$

and we came to write:

$$S_0=-m_0c^2\int\sqrt{1-\frac{v^2}{c^2}}\mathrm{d}t \tag{12.4.55}$$

Now let us show something interesting! Let us recall that for the Minkowski space-time, we got:

$$\mathrm{d}s^2=c^2\mathrm{d}t^2-(\mathrm{d}x^2+\mathrm{d}y^2+\mathrm{d}z^2) \tag{12.4.56}$$

and restricting ourselves to one spatial dimension, we get as relation:

$$\mathrm{d}s^2=c^2\mathrm{d}t-\mathrm{d}x^2\Leftrightarrow \mathrm{d}s^2=c^2\mathrm{d}t^2\left(1-\frac{\mathrm{d}x^2}{c^2\mathrm{d}t^2}\right)=c^2\mathrm{d}t^2\left(1-\frac{v^2}{c^2}\right) \tag{12.4.57}$$

Therefore:

$$\mathrm{d}s=c\mathrm{d}t\sqrt{1-\frac{v^2}{c^2}} \tag{12.4.58}$$

and then ... well that's the way, if we put:

$$\boxed{S=-m_0c\int \mathrm{d}s} \tag{12.4.59}$$

we finally have:

$$S=-m_0c\int \mathrm{d}s=-m_0c\int c\mathrm{d}t\sqrt{1-\frac{v^2}{c^2}}=-m_0c^2\int\sqrt{1-\frac{v^2}{c^2}}\mathrm{d}t \tag{12.4.60}$$

so we fall back on the same action from a more general form (pure) action that is:

$$S=-m_0c\int \mathrm{d}s \tag{12.4.61}$$

result that we had also proved in the section of Electrodynamics (see page 4126)!! We can even do better in terms of elegance ...! If we observe well the developments of the previous lines, we observe that in facts the relation:

$$\mathrm{d}s=c\mathrm{d}t\sqrt{1-\frac{v^2}{c^2}} \tag{12.4.62}$$

And this last relation is the one-dimensional case of the more general following relation:

$$\mathrm{d}s=\mathrm{d}t\sqrt{\frac{g_{\mu\nu}\dot{x}^\mu\dot{x}^\nu}{c^2}}=\frac{1}{c}\sqrt{g_{\mu\nu}\dot{x}^\mu\dot{x}^\nu}\mathrm{d}t \tag{12.4.63}$$

with as defined earlier above:

$$x^0=ct,x^1=x,x^2=y,x^3=z \tag{12.4.64}$$

and therefore:

$$\dot{x}^0=c,\dot{x}^1=v_x,\dot{x}^2=v_y,\dot{x}^3=v_z \tag{12.4.65}$$

Thus we have the "Fitzgerald-Lorentz factor" or simply "Lorentz factor" that is given in general form by:

$$\boxed{\gamma=\frac{1}{c}\sqrt{g_{\mu\nu}\dot{x}^\mu\dot{x}^\nu}} \tag{12.4.66}$$

as a generalization of Special Relativity!

Therefore the Lagrangian of a relativistic free particle is in general written:

$$L=-m_0c^2\sqrt{\eta_{\mu\nu}\frac{\mathrm{d}x^\mu}{\mathrm{d}t}\frac{\mathrm{d}x^\mu}{\mathrm{d}t}}=-m_0c^2\sqrt{\eta_{\mu\nu}\dot{x}^\mu\dot{x}^\nu} \tag{12.4.67}$$

Remark

Notice, that the Lagrangian above is a homogeneous function of degree one, i.e.:

$$L(\lambda\dot{x}^\mu(t))=\lambda L(\dot{x}^\mu(t)) \tag{12.4.68}$$

Therefore as seen in the section of Analytical Mechanics (see page 3181), the Hamiltonian is zero!

This being done, let us come back on our topic... In a space without potential field, we have proved in the section of Analytical Mechanics that the Lagrangian is reduced to the simplest expression of the kinetic energy (see page 3170) such that:

$$L=\frac{1}{2}m_0v^2=\frac{1}{2}m_0\left(\frac{\mathrm{d}x}{\mathrm{d}t}\right)^2 \tag{12.4.69}$$

If we wish to generalize this relation for it to be valid in any type of space (curved or flat), we must introduce the curvilinear coordinates as we have studied them in the section of Tensor Calculus (see page 2092).

In a first time, this gives:

$$L=\frac{1}{2}m_0\left(\frac{\mathrm{d}s}{\mathrm{d}t}\right)^2 \tag{12.4.70}$$

where for recall $\mathrm{d}s$ is the curvilinear abscissa of the path.

And we have proved in the section of Differential Geometry that (see page 2850):

$$\mathrm{d}s=\left[g_{ij}\frac{\partial u^i}{\partial\alpha}\frac{\partial u^j}{\partial\alpha}\right]^{1/2}\mathrm{d}\alpha \tag{12.4.71}$$

The latter relation is written in the context of relativistic mechanics in a most standard way:

$$\mathrm{d}s=\left[g_{\alpha\beta}\frac{\partial x^\alpha}{\partial\tau}\frac{\partial x^\beta}{\partial\tau}\right]^{1/2}\mathrm{d}\tau \tag{12.4.72}$$

where τ is a parameter that in relativistic mechanics if for recall the proper time of the particle.

Before we focus on curved spaces described by the metric $g_{\alpha\beta}$ (which we will do during our proof of the free generalized Lagrangian), let us restrict us to Euclidean space with the metric (this will be a good exercise to understand) given by the Minkowski matrix (see section Special Relativity page 5705):

$$g_{\alpha\beta}=\begin{bmatrix}1&0&0&0\\0&-1&0&0\\0&0&-1&0\\0&0&0&-1\end{bmatrix} \tag{12.4.73}$$

which we denote $\eta_{\alpha\beta}$ to differentiate it from others (because most often used). Finally we in Euclidean space:

$$S=-mc\int\mathrm{d}s=-mc\int\left(\eta_{\alpha\beta}\frac{\partial x^\alpha}{\partial\tau}\frac{\partial x^\beta}{\partial\tau}\right)\mathrm{d}\tau \tag{12.4.74}$$

Now let us apply the variational principle:

$$\delta S=-mc\int\delta(\mathrm{d}s) \tag{12.4.75}$$

The variation $\mathrm{d}s$ can be found simply from the variation of $\mathrm{d}s^2$:

$$(\mathrm{d}s)^2=\mathrm{d}s^2=\eta_{\alpha\beta}\frac{\partial x^\alpha}{\partial t}\frac{\partial x^\beta}{\partial t}\mathrm{d}t^2=\eta_{\alpha\beta}\mathrm{d}x^\alpha\mathrm{d}x^\beta \tag{12.4.76}$$

we find:

$$\delta(\mathrm{d}s)^2=2\mathrm{d}s\delta(\mathrm{d}s)=\eta_{\alpha\beta}\delta(\mathrm{d}x^\alpha\mathrm{d}x^\beta)=\eta_{\alpha\beta}\delta\mathrm{d}x^\alpha\mathrm{d}x^\beta+\eta_{\alpha\beta}\mathrm{d}x^2\delta\mathrm{d}x^\beta=2\eta_{\alpha\beta}\delta(\mathrm{d}x^\alpha)\mathrm{d}x^\beta \tag{12.4.77}$$

The factor "2" is here because by symmetry of the Euclidean space, the variations of $\mathrm{d}x^\alpha$ and $\mathrm{d}x^\beta$ are equal.

Remark

As we will see later, this relation $\delta(\mathrm{d}s)^2$ will not be the same anymore when dealing with curved spaces.

Simplifying a bit, we get:

$$2\mathrm{d}s\delta(\mathrm{d}s)=2\eta_{\alpha\beta}\delta(\mathrm{d}x^{\alpha})\mathrm{d}x^{\beta}\Leftrightarrow\delta(\mathrm{d}s)=\eta_{\alpha\beta}\delta(\mathrm{d}x^{\alpha})\frac{\mathrm{d}x^{\beta}}{\mathrm{d}s} \qquad (12.4.78)$$

Which is equivalent to write:

$$\delta(\mathrm{d}s)=\eta_{\alpha\beta}\mathrm{d}(\delta x^{\alpha})\frac{\mathrm{d}x^{\beta}}{\mathrm{d}s}=\eta_{\alpha\beta}\frac{\mathrm{d}(\delta x^{\alpha})}{\mathrm{d}\tau}\frac{\mathrm{d}x^{\beta}}{\mathrm{d}s}\mathrm{d}\tau \qquad (12.4.79)$$

We can now go back to the action:

$$\delta S=-mc\int\delta(\mathrm{d}s)=-mc\int\eta_{\alpha\beta}\frac{\mathrm{d}(\delta x^{\alpha})}{\mathrm{d}\tau}\frac{\mathrm{d}x^{\beta}}{\mathrm{d}s}\mathrm{d}\tau \qquad (12.4.80)$$

We rewrite the preceding integral as following (it will be easier to treat):

$$\delta S=-mc\int\eta_{\alpha\beta}\frac{\mathrm{d}(\delta x^{\alpha})}{\mathrm{d}\tau}\frac{\mathrm{d}x^{\beta}}{\mathrm{d}s}\mathrm{d}\tau=-mc\int_{\tau_2}^{\tau_1}\mathrm{d}\tau\frac{\mathrm{d}}{\mathrm{d}\tau}\left(\eta_{\alpha\beta}\delta x^{\alpha}\frac{\mathrm{d}x^{\beta}}{\mathrm{d}s}\right)+\int_{\tau_2}^{\tau_1}\mathrm{d}\tau\delta x^{\alpha}\left(mc\eta_{\alpha\beta}\frac{\mathrm{d}}{\mathrm{d}\tau}\frac{\mathrm{d}x^{\beta}}{\mathrm{d}s}\right) \qquad (12.4.81)$$

Indeed, let check that this form is similar:

$$\begin{aligned}\delta S&=-mc\int_{\tau_2}^{\tau_1}\mathrm{d}\tau\frac{\mathrm{d}}{\mathrm{d}\tau}\left(\eta_{\alpha\beta}\delta x^{\alpha}\frac{\mathrm{d}x^{\beta}}{\mathrm{d}s}\right)+\int_{\tau_2}^{\tau_1}\mathrm{d}\tau\delta x^{\alpha}\left(mc\eta_{\alpha\beta}\frac{\mathrm{d}}{\mathrm{d}\tau}\frac{\mathrm{d}x^{\beta}}{\mathrm{d}s}\right)\\&=-mc\cancel{\int_{\tau_2}^{\tau_1}\mathrm{d}\tau\left(\frac{\eta_{\alpha\beta}}{\underbrace{\mathrm{d}\tau}_{=0}}\delta x^{\alpha}\frac{\mathrm{d}x^{\beta}}{\mathrm{d}s}\right)}-mc\int_{\tau_2}^{\tau_1}\mathrm{d}t\left(\eta_{\alpha\beta}\frac{\mathrm{d}(\delta x^{\beta})}{\mathrm{d}\tau}\frac{\mathrm{d}x^{\beta}}{\mathrm{d}s}\right)-mc\cancel{\int_{\tau_2}^{\tau_1}\mathrm{d}t\left(\eta_{\alpha\beta}\delta x^{\alpha}\frac{\mathrm{d}}{\mathrm{d}t}\frac{\mathrm{d}x^{\beta}}{\mathrm{d}s}\right)}\\&+\cancel{\int_{\tau_2}^{\tau_1}\mathrm{d}\tau\delta x^{\alpha}\left(mc\eta_{\alpha\beta}\frac{\mathrm{d}}{\mathrm{d}\tau}\frac{\mathrm{d}x^{\beta}}{\mathrm{d}s}\right)}=-mc\int_{\tau_2}^{\tau_1}\eta_{\alpha\beta}\frac{\mathrm{d}(\delta x^{\alpha})}{\mathrm{d}s}\mathrm{d}t\end{aligned} \qquad (12.4.82)$$

So let us come back to our integral:

$$\delta S=-mc\int_{\tau_2}^{\tau_1}\mathrm{d}\tau\frac{\mathrm{d}}{\mathrm{d}\tau}\left(\eta_{\alpha\beta}\delta x^{\alpha}\frac{\mathrm{d}x^{\beta}}{\mathrm{d}s}\right)+\int_{\tau_2}^{\tau_1}\mathrm{d}\tau\delta x^{\alpha}\left(mc\eta_{\alpha\beta}\frac{\mathrm{d}}{\mathrm{d}\tau}\frac{\mathrm{d}x^{\beta}}{\mathrm{d}s}\right) \qquad (12.4.83)$$

We have then two integrals that it will be a bit easier to analyse. The first integral:

$$-mc\int_{\tau_2}^{\tau_1}\mathrm{d}\left(\eta_{\alpha\beta}\delta x^{\alpha}\frac{\mathrm{d}x^{\beta}}{\mathrm{d}s}\right)=-m\left[\eta_{\alpha\beta}\delta x^{\alpha}\frac{\mathrm{d}x^{\beta}}{\mathrm{d}s}\right]_{\tau_2}^{\tau_1} \qquad (12.4.84)$$

simply gives an expression evaluated to the temporal extremities (τ_1, τ_2). Therefore, as the values x^α are perfectly known at the time ends, the variational δx^α is zero at the both extremities and this integral is therefore zero.

Then we are left only with this integral:

$$\delta S = \int_{\tau_2}^{\tau_1} \mathrm{d}\tau \delta x^\alpha \left(mc\eta_{\alpha\beta} \frac{\mathrm{d}}{\mathrm{d}\tau} \frac{\mathrm{d}x^\beta}{\mathrm{d}s} \right) \tag{12.4.85}$$

So for the variational principle (see section Analytical Mechanics page 3131):

$$\delta S = 0 \tag{12.4.86}$$

is respected, we must have:

$$\frac{\mathrm{d}}{\mathrm{d}\tau} \left(mc \frac{\mathrm{d}x^\beta}{\mathrm{d}s} \right) = 0 \tag{12.4.87}$$

Now, we can write this expression explicitly. Indeed, we have:

$$mc \frac{\mathrm{d}x^\beta}{\mathrm{d}s} = mc \left(\frac{\mathrm{d}(c\tau)}{\mathrm{d}s}, \frac{\mathrm{d}x}{\mathrm{d}s}, \frac{\mathrm{d}y}{\mathrm{d}s}, \frac{\mathrm{d}z}{\mathrm{d}s} \right) \tag{12.4.88}$$

Remember also that we have proved earlier above that:

$$\mathrm{d}s = c\mathrm{d}t\sqrt{1-\beta^2} \Leftrightarrow \frac{\mathrm{d}\tau}{\mathrm{d}s} = \frac{1}{c\sqrt{1-\beta^2}} = \frac{\gamma}{c} \tag{12.4.89}$$

and that we have:

$$\frac{\mathrm{d}x}{\mathrm{d}s} = \frac{\mathrm{d}x}{\mathrm{d}\tau} \frac{\mathrm{d}\tau}{\mathrm{d}s} = v_x \frac{\mathrm{d}\tau}{\mathrm{d}s} = \frac{v_x \gamma}{c} \tag{12.4.90}$$

Therefore:

$$mc \left(\frac{\mathrm{d}(c\tau)}{\mathrm{d}s}, \frac{\mathrm{d}x}{\mathrm{d}s}, \frac{\mathrm{d}y}{\mathrm{d}s}, \frac{\mathrm{d}z}{\mathrm{d}s} \right) = m\gamma \left(c, v_x, v_y, v_z \right) \tag{12.4.91}$$

Now, let us recall that during our study of Special Relativity (see page 5687), we have proved the path that led us to define the linear momentum four-vector:

$$p^\nu = \left(\frac{E}{c}, p_x, p_y, p_z \right) = \left(\frac{E}{c}, \vec{p} \right) = m\gamma(c, \vec{v}) \tag{12.4.92}$$

So finally, what cancel the variational of the action integral can be written:

$$\boxed{\frac{\mathrm{d}p^\nu}{\mathrm{d}\tau} = 0} \tag{12.4.93}$$

We thus fall back on the conservation equation of linear momentum (momentum conservation) that we name in the framework of General Relativity "equation of motion". This form of the equation of motion seems dependent on the mass but by digging a bit, we will see that it is fact not.

Multiplying this relation by $\eta_{\mu\nu}$ we can also write:

$$\boxed{\frac{\mathrm{d}p_\mu}{\mathrm{d}\tau}=0} \tag{12.4.94}$$

and the same for another observer:

$$\frac{\mathrm{d}p_\mu}{\mathrm{d}\tau\gamma}=0 \Leftrightarrow \frac{\mathrm{d}p_\mu}{\mathrm{d}\tau'}=0 \tag{12.4.95}$$

In other words, the linear momentum of the particle remains constant along its world line.

But we can also write:

$$\frac{\mathrm{d}p^v}{\mathrm{d}\tau}=\frac{\mathrm{d}p^v}{\left(\dfrac{\mathrm{d}s}{c}\gamma\right)}=0 \tag{12.4.96}$$

Therefore:

$$\boxed{\frac{\mathrm{d}p^v}{\mathrm{d}s}=0} \tag{12.4.97}$$

An even more important form of movement equation can be obtained. Indeed using the relations just proved above we can write:

$$p^v=mc\frac{mc}{\dfrac{\mathrm{d}x^v}{\mathrm{d}s}} \tag{12.4.98}$$

Therefore:

$$\frac{\mathrm{d}p^v}{\mathrm{d}s}=\frac{\mathrm{d}}{\mathrm{d}s}\left(mc\frac{\mathrm{d}x^v}{\mathrm{d}s}\right)=mc\frac{\mathrm{d}}{\mathrm{d}s}\left(\frac{\mathrm{d}x^v}{\mathrm{d}s}\right)=0 \tag{12.4.99}$$

Hence:

$$\boxed{\frac{\mathrm{d}^2x^v}{\mathrm{d}s^2}=0} \tag{12.4.100}$$

This relation is therefore thhe "massless" equation of motion in Euclidean space or in other words, in a Minkowski space-time type! That means that there exists a falling coordinate system wherein the motion of the particle is in an uniform movement in space-time.

It will be very interesting to compare it later with the equation of motion in a curved space as we will see later (named "geodesic equation").

Remark

It is equivalent to write the relations of equations of motion with respect to the curvilinear abscissa $\mathrm{d}s$ or the proper time $\mathrm{d}t$ (traditionally denoted by $\mathrm{d}\tau$ in the field of General Relativity).

We can now prove that the previous equation of motion, just like the geodesic equation that we will see afterwards, is invariant under Lorentz transformation. Indeed:

$$L^{\mu}_{v}\frac{\mathrm{d}^2 x^v}{\mathrm{d}s^2}=\frac{\mathrm{d}^2(L^{\mu}_{v}x^v)}{\mathrm{d}s^2}=\frac{\mathrm{d}^2 x'^v}{\mathrm{d}s^2}=0 \tag{12.4.101}$$

Now let us see a more general form of the equation of motion for any kind of space. The aim is to highlight, and this in a few lines of calculations, that the movement followed by a free particle is independent of its mass (you can already anticipate the interpretation of the path of a photon in a curved space...!).

Let us first recall that we have proved in the section of Tensor Calculus (and previously) that:

$$\mathrm{d}s=\left[g_{ij}\frac{\partial u^i}{\partial\alpha}\frac{\partial u^j}{\partial\alpha}\right]^{1/2}\mathrm{d}\alpha \tag{12.4.102}$$

giving us for the generalized Lagrangian of a free particle with $\mathrm{d}\alpha=\mathrm{d}\tau$, $u^i=x^\alpha$, $u^j=x^\beta$ (although we fall back on the general expression of the kinetic energy as there is no potential for a free particle):

$$\boxed{L=\frac{1}{2}mg_{\alpha\beta}\frac{\partial x^\alpha}{\partial\tau}\frac{\partial x^\beta}{\partial\tau}} \tag{12.4.103}$$

where for recall τ is the proper time[44] of the particle, it is an invariant!

Remark

This relation is named the "geodesic lagrangian" by some textbooks authors.

This allows us to write (caution! the reader must remember the different relations that we had determined during our study of the Lagrangian formalism in the section dealing with Analytical Mechanics):

$$p_\alpha=\frac{\partial L}{\partial\dot{x}^\alpha}=mg_{\alpha\beta}\frac{\mathrm{d}x^\beta}{\mathrm{d}\tau} \tag{12.4.104}$$

Remark

The elimination of the $1/2$ Lagrangian factor results from the symmetry of the metric tensor. If that latter is not symmetric, we can always characterize it by a tensor that is.

Indeed, for recall (see section Tensor Calculus page 2088), given $\vec{x}$ a vector of coordinates $x_1,\ldots,x_n$ and given:

$$q=A_{ij}x_ix_j \tag{12.4.105}$$

The A_{ij} are not symmetric a priori, but we can write:

$$q=\frac{1}{2}(A_{ij}+A_{ji})x_ix_j \tag{12.4.106}$$

---

[44] The proper time is for recall a kind of imaginary clock that travels on the particle and whatever observers watch the clock, they will mathematically agree on the value of the time interval between two "Tic" of the clock.

We put afterwards:

$$B_{ij}=\frac{1}{2}(A_{ij}+A_{ji})x_ix_j \tag{12.4.107}$$

Therefore:

$$q=B_{ij}x_ix_j \tag{12.4.108}$$

And the B_{ij} are symmetric.

The quadratic form q can thus always be written with a symmetric matrix, there is even a bijection. The conclusion is that a metric tensor must be symmetric if we want to characterize it by the quadratic form it defines.

The mathematical interlude having ended, let us continue our physical development. As a consequence of the last relation, the expression of the Hamiltonian obviously becomes:

$$H=p_\alpha\dot{x}^\alpha-L=L \tag{12.4.109}$$

since we consider to be in a space without potential field anymore. Since the square of the velocity is therefore constant over the entire trajectory, we have:

$$\frac{\mathrm{d}H}{\mathrm{d}t}=\frac{\mathrm{d}L}{\mathrm{d}t}=0 \tag{12.4.110}$$

Let us now establish the equations of motion of any body. We have:

$$\frac{\partial L}{\partial x^\nu}=\frac{1}{2}m\frac{\partial g_{\alpha\beta}}{\partial x^\nu}\dot{x}^\alpha\dot{x}^\beta \qquad \text{and} \qquad \frac{\partial L}{\partial \dot{x}^\nu}=mg_{\nu\beta}\dot{x}^\beta \tag{12.4.111}$$

and as:

$$\frac{\partial L}{\partial x^\nu}=\frac{\mathrm{d}}{\mathrm{d}t}\frac{\partial L}{\partial \dot{x}^\nu}=\frac{\mathrm{d}}{\mathrm{d}t}\frac{\partial L}{\partial\frac{\mathrm{d}}{\mathrm{d}t}(x^\nu)} \tag{12.4.112}$$

then:

$$\frac{1}{2}m\frac{\partial g_{\alpha\beta}}{\partial x^\nu}\dot{x}^\alpha\dot{x}^\beta=\frac{\mathrm{d}}{\mathrm{d}t}\left(mg_{\nu\beta}\dot{x}^\beta\right) \tag{12.4.113}$$

hence:

$$\frac{\mathrm{d}}{\mathrm{d}t}\left(\frac{\partial L}{\partial \dot{x}^\nu}\right)=m\frac{\mathrm{d}}{\mathrm{d}t}\left(g_{\nu\beta}\dot{x}^\beta\right)=mg_{\nu\beta}\ddot{x}^\beta+m\frac{\mathrm{d}g_{\nu\beta}}{\mathrm{d}t}\frac{\partial x^\alpha}{\partial x^\alpha}\dot{x}^\beta=mg_{\nu\beta}\ddot{x}^\beta+m\frac{\partial g_{\nu\beta}}{\partial x^\alpha}\dot{x}^\alpha\dot{x}^\beta \tag{12.4.114}$$

By putting everything together we get:

$$mg_{\nu\beta}\ddot{x}^\beta+m\frac{\partial g_{\nu\beta}}{\partial x^\alpha}\dot{x}^\alpha\dot{x}^\beta=\frac{1}{2}m\frac{\partial g_{\alpha\beta}}{\partial x^\nu}\dot{x}^\alpha\dot{x}^\beta \tag{12.4.115}$$

that we can write identically for the $\ddot{x}^\alpha$ by proceeding in the same way as above.

The preceding relation therefore gives the trajectory of a body in motion, in a space without a potential field, as a function of its curvilinear coordinates and of the metric of the space under consideration.

What is particularly interesting in this result is that the mass m is (again!) eliminated identically in this equation of motion:

$$g_{\nu\beta}\ddot{x}^{\beta}+\left(\frac{\partial g_{\nu\beta}}{\partial x^{\alpha}}-\frac{1}{2}\frac{\partial g_{\alpha\beta}}{\partial x^{\nu}}\right)\dot{x}^{\alpha}\dot{x}^{\beta}=0 \qquad (12.4.116)$$

Notice that we could have used another invariant parameter as well as the proper time τ such as the curvilinear abscissa $\mathrm{d}s$. Hence the preceding equation should be written:

$$\boxed{g_{\nu\beta}\frac{\partial^2 x^{\beta}}{\partial s^2}+\left(\frac{\partial g_{\nu\beta}}{\partial x^{\beta}}-\frac{1}{2}\frac{\partial g_{\alpha\beta}}{\partial x^{\nu}}\right)\frac{\partial x^{\alpha}}{\partial s}\frac{\partial x^{\beta}}{\partial s}=0} \qquad (12.4.117)$$

We can still simplify this relation, but we will keep this simplification for the second proof of the equation of motion in any space (by making use of the variational principle this time) just further below.

It is very (very) interesting to observe that if we restrict the metric to that of a Euclidean space:

$$\eta_{\nu\beta}\frac{\partial^2 x^{\beta}}{\partial s^2}+\left(\frac{\partial \eta_{\nu\beta}}{\partial x^{\beta}}-\frac{1}{2}\frac{\partial \eta_{\alpha\beta}}{\partial x^{\nu}}\right)\frac{\partial x^{\alpha}}{\partial s}\frac{\partial x^{\beta}}{\partial s}=0 \qquad (12.4.118)$$

with:

$$\frac{\partial \eta_{\nu\beta}}{\partial x^{\alpha}}=\frac{\partial \eta_{\alpha\beta}}{\partial x^{\nu}}=0 \qquad (12.4.119)$$

We then have the following simplification:

$$\eta_{\nu\beta}\frac{\partial^2 x^{\beta}}{\partial s^2}+\left(0-\frac{1}{2}\cdot 0\right)\frac{\partial x^{\alpha}}{\partial s}\frac{\partial x^{\beta}}{\partial s}=0 \qquad (12.4.120)$$

That it remains only:

$$\eta_{\nu\beta}\frac{\partial^2 x^{\beta}}{\partial s^2}=0 \qquad (12.4.121)$$

By lowering the indices with the signature it remains:

$$\frac{\partial^2 x_{\nu}}{\partial s^2}=0 \qquad (12.4.122)$$

We thus fall back on the first equation of the motion obtained for a flat space! The result is remarkable!

The conclusions is that at the same initial conditions of curvilinear position and velocity in a space (flat or curved) without a potential field (this is what we could think at least according to our initial hypotheses ...), corresponds the same trajectory whatever the mass m of the particle (even for photons - light - whose rest mass is zero!).

We can now study the principle of least action in order to seek the shortest path (both spatially and temporally!) between two points in a given geometric space before addressing the much more complex case of the Lagrangian which takes into account the tensor field...

12.4.3.1 Geodesic equations

Let us now turn to the same result, but this time using the variational principle. We will fall on the same equation as before for any kind of space with the difference that this time we will take the time to simplify it to arrive at the "geodesic equation".

Starting from (see previous developments):

$$\mathrm{d}s=(g_{ij}\mathrm{d}x^i\mathrm{d}x^j)^{1/2} \tag{12.4.123}$$

with a parametrization such that x^i and x^j depend of a temporal or spatial parameter.

For a given surface in parametric form, we therefore seek to minimize the length of an arc $\mathrm{d}s$ by applying the variational principle (not dependent on time) because the photons can not have a faster path in the temporal sense of the term between two points but only a shorter path - in the metric sense of the term!):

$$\delta S=\int\limits_a^b \mathrm{d}(\mathrm{d}s)=\int\limits_a^b \delta(\mathrm{d}s)=0 \tag{12.4.124}$$

in natural units. Or:

$$\delta(\mathrm{d}s^2)=2\mathrm{d}s\delta\mathrm{d}s=\delta(g_{ij}\mathrm{d}x^i\mathrm{d}x^j) \tag{12.4.125}$$

By developing, and as the indices have the same range of variation:

$$\begin{aligned}\delta(g_{ij}\mathrm{d}x^i\mathrm{d}x^j)&=\left(\frac{\partial g_{ij}}{\partial x^k}\delta\mathrm{d}x^k\right)\mathrm{d}x^i\mathrm{d}x^j+g_{ij}\mathrm{d}x^j\delta\mathrm{d}x^i+g_{ij}\mathrm{d}x^i\delta\mathrm{d}x^j\\&=\left(\frac{\partial g_{ij}}{\partial x^k}\delta\mathrm{d}x^k\right)\mathrm{d}x^i\mathrm{d}x^j+2g_{ij}\mathrm{d}x^i\delta\mathrm{d}x^j\end{aligned} \tag{12.4.126}$$

hence (we have already multiplied the expression after the second equality by $\mathrm{d}s/\mathrm{d}s$ by anticipating the integral that follows):

$$\delta(\mathrm{d}s)=\frac{\delta(\mathrm{d}s^2)}{2\mathrm{d}s}=\frac{1}{2}\frac{\mathrm{d}x^i}{\mathrm{d}s}\frac{\mathrm{d}x^j}{\mathrm{d}s}\left(\frac{\partial g_{ij}}{\partial x^k}\delta\mathrm{d}x^k\right)\mathrm{d}s+g_{ij}\frac{\mathrm{d}x^i}{\mathrm{d}s}\frac{\delta\mathrm{d}x^j}{\mathrm{d}s}\mathrm{d}s \tag{12.4.127}$$

Then, we must introduce this development under the integral:

$$\int\limits_a^b\delta(\mathrm{d}s)=\int\limits_a^b\frac{1}{2}\frac{\mathrm{d}x^i}{\mathrm{d}s}\frac{\mathrm{d}x^j}{\mathrm{d}s}\left(\frac{\partial g_{ij}}{\partial x^k}\delta\mathrm{d}x^k\right)\mathrm{d}s+\int\limits_a^b g_{ij}\frac{\mathrm{d}x^i}{\mathrm{d}s}\frac{\delta\mathrm{d}x^j}{\mathrm{d}s}\mathrm{d}s=0 \tag{12.4.128}$$

Working on the second integral (after the equality), we put:

$$u=g_{ij}\frac{\mathrm{d}x^i}{\mathrm{d}s}\qquad\text{and}\qquad v'=\frac{\delta\mathrm{d}x^j}{\mathrm{d}s}\mathrm{d}s \tag{12.4.129}$$

So by integration by part (see section Differential and Integral Calculus page 1532):

$$\int\limits_a^b g_{ij}\frac{\mathrm{d}x^i}{\mathrm{d}s}\frac{\delta\mathrm{d}x^j}{\mathrm{d}s}\mathrm{d}s=uv'\Big|_a^b-\int\limits_a^b u'v\mathrm{d}s \tag{12.4.130}$$

becomes:

$$\int\limits_a^b g_{ij}\frac{\mathrm{d}x^i}{\mathrm{d}s}\frac{\delta \mathrm{d}x^j}{\mathrm{d}s}\mathrm{d}s = g_{ij}\frac{\mathrm{d}x^i}{\mathrm{d}s}\delta\mathrm{d}x^j\mathrm{d}s\bigg|_a^b - \int\limits_a^b \frac{\mathrm{d}}{\mathrm{d}s}\left(g_{ij}\frac{\mathrm{d}x^i}{\mathrm{d}s}\right)\delta\mathrm{d}x^j\mathrm{d}s \tag{12.4.131}$$

Thus finally:

$$\int\limits_a^b \delta(\mathrm{d}s) = \int\limits_a^b \frac{1}{2}\frac{\mathrm{d}x^i}{\mathrm{d}x}\frac{\mathrm{d}x^j}{\mathrm{d}s}\left(\frac{\partial g_{ij}}{\partial x^k}\delta x^k\right)\mathrm{d}s + g_{ij}\frac{\mathrm{d}x^i}{\mathrm{d}s}\delta\mathrm{d}x^j\mathrm{d}s\bigg|_a^b - \int\limits_a^b \frac{\mathrm{d}}{\mathrm{d}s}\left(g_{ij}\frac{\mathrm{d}x^i}{\mathrm{d}s}\right)\delta\mathrm{d}x^j\mathrm{d}s = 0 \tag{12.4.132}$$

The non-integrated term below:

$$g_{ij}\frac{\mathrm{d}x^i}{\mathrm{d}s}\delta\mathrm{d}x^j\mathrm{d}s\bigg|_a^b \cong 0 \tag{12.4.133}$$

is negligible because of the presence of the factor $\delta\mathrm{d}x^j$: Therefore:

$$\begin{aligned}\int\limits_a^b \delta(\mathrm{d}s) &= \int\limits_a^b \frac{1}{2}\frac{\mathrm{d}x^i}{\mathrm{d}x}\frac{\mathrm{d}x^j}{\mathrm{d}s}\left(\frac{\partial g_{ij}}{\partial x^k}\delta x^k\right)\mathrm{d}s - \int\limits_a^b \frac{\mathrm{d}}{\mathrm{d}s}\left(g_{ij}\frac{\mathrm{d}x^i}{\mathrm{d}s}\right)\delta\mathrm{d}x^j\mathrm{d}s\\ &= \int\limits_a^b \left[\frac{1}{2}\frac{\mathrm{d}x^i}{\mathrm{d}x}\frac{\mathrm{d}x^j}{\mathrm{d}s}\left(\frac{\partial g_{ij}}{\partial x^k}\delta x^k\right) - \frac{\mathrm{d}}{\mathrm{d}s}\left(g_{ij}\frac{\mathrm{d}x^i}{\mathrm{d}s}\right)\delta\mathrm{d}x^j\right]\mathrm{d}s = 0\end{aligned} \tag{12.4.134}$$

We make a change of index:

$$\int\limits_a^b \delta(\mathrm{d}s) = \int\limits_a^b \left[\frac{1}{2}\frac{\mathrm{d}x^i}{\mathrm{d}x}\frac{\mathrm{d}x^j}{\mathrm{d}s}\left(\frac{\partial g_{ij}}{\partial x^k}\delta x^k\right) - \frac{\mathrm{d}}{\mathrm{d}s}\left(g_{ik}\frac{\mathrm{d}x^i}{\mathrm{d}s}\right)\delta\mathrm{d}x^k\right]\mathrm{d}s = 0 \tag{12.4.135}$$

Which allows us to factorize δx^k:

$$\int\limits_a^b \delta(\mathrm{d}s) = \int\limits_a^b \left[\frac{1}{2}\frac{\mathrm{d}x^i}{\mathrm{d}x}\frac{\mathrm{d}x^j}{\mathrm{d}s}\frac{\partial g_{ij}}{\partial x^k} - \frac{\mathrm{d}}{\mathrm{d}s}\left(g_{ik}\frac{\mathrm{d}x^i}{\mathrm{d}s}\right)\right]\delta\mathrm{d}x^k\mathrm{d}s = 0 \tag{12.4.136}$$

As $\delta\mathrm{d}x^k$ and $\mathrm{d}s$ are different from zero, it is the integrand that must be zero:

$$\frac{1}{2}\frac{\mathrm{d}x^i}{\mathrm{d}x}\frac{\mathrm{d}x^j}{\mathrm{d}s}\frac{\partial g_{ij}}{\partial x^k} - \frac{\mathrm{d}}{\mathrm{d}s}\left(g_{ik}\frac{\mathrm{d}x^i}{\mathrm{d}s}\right) = 0 \tag{12.4.137}$$

By developing the second term:

$$\frac{1}{2}\frac{\mathrm{d}x^i}{\mathrm{d}x}\frac{\mathrm{d}x^j}{\mathrm{d}s}\frac{\partial g_{ij}}{\partial x^k} - \frac{\mathrm{d}g_{ik}}{\mathrm{d}s}\frac{\mathrm{d}x^i}{\mathrm{d}s} - g_{ik}\frac{\mathrm{d}}{\mathrm{d}s}\frac{\mathrm{d}x^i}{\mathrm{d}s} = 0 \tag{12.4.138}$$

Which can also be written (in the physicist way of life...)

$$\frac{1}{2}\frac{\mathrm{d}x^i}{\mathrm{d}x}\frac{\mathrm{d}x^j}{\mathrm{d}s}\frac{\partial g_{ij}}{\partial x^k} - \frac{\mathrm{d}x^i}{\mathrm{d}s}\frac{\partial g_{ik}}{\partial x^j}\frac{\mathrm{d}x^j}{\mathrm{d}s} - g_{ik}\frac{\mathrm{d}}{\mathrm{d}s}\frac{\mathrm{d}x^i}{\mathrm{d}s} = 0 \tag{12.4.139}$$

Which simplifies into:

$$\boxed{g_{ik}\frac{\mathrm{d}^2x^i}{\mathrm{d}s^2}+\left(\frac{\partial g_{ik}}{\partial x^j}-\frac{1}{2}\frac{\partial g_{ij}}{\partial x^k}\right)=\frac{\mathrm{d}x^j}{\mathrm{d}s}\frac{\mathrm{d}x^j}{\mathrm{d}s}=0} \tag{12.4.140}$$

We fall back (again!) on the system of equations which defines the "geodesics", that is to say the straight lines of $\mathcal{E}^n$. These latter then constitute the extremities of the integral which measures the length of a curve arc joining two given points in $\mathcal{E}^n$.

This last equation is the one which interests us in the case of the free Lagrangian. Indeed, if we take the extreme case of light (or photons if you prefer), the latter will not seek the fastest path at the temporal level. This would totally contradict the postulate of invariance to see the light accelerate according to the path !!! In this context, it means that on the spatio-temporal framework, the only thing that has meaning is the shortest spatial path and not the shortest temporal path! This is why the latter equation is named the "geodesic equation" or also "generalized Euler-Lagrange equation".

However, we can write this last equation in a more condensed form by introducing the Christoffel symbols if the metric is a symmetric tensor, that is to say if $g_{\alpha\beta}=-g_{\beta\alpha}$.

Indeed:

$$g_{ik}\frac{\mathrm{d}^2x^i}{\mathrm{d}s^2}+\frac{1}{2}\left(2\frac{\partial g_{ik}}{\partial x^j}-\frac{\partial g_{ij}}{\partial x^k}\right)\frac{\mathrm{d}x^i}{\mathrm{d}s}\frac{\mathrm{d}x^j}{\mathrm{d}s}=g_{ik}\frac{\mathrm{d}^2x^i}{\mathrm{d}s^2}+\frac{1}{2}\left(\frac{\partial g_{ik}}{\partial x^j}+\frac{\partial g_{ik}}{\partial x^i}-\frac{\partial g_{ij}}{\partial x^k}\right)\frac{\mathrm{d}x^i}{\mathrm{d}s}\frac{\mathrm{d}x^j}{\mathrm{d}x^j}\mathrm{d}s=0 \tag{12.4.141}$$

And as the Christoffel symbol of the first kind (see section Tensor Calculus page 2107) is defined by:

$$\Gamma_{ikj}=\frac{1}{2}\left(\partial_j g_{ik}+\partial_i g_{kj}-\partial_k g_{ij}\right) \tag{12.4.142}$$

Remark

It is important to remember that this symbol contains almost all information about the space-time metric! We will see an example further below where in a locally inertial frame this Christoffel symbol will be equal to zero.

Then the Euler-Lagrange equation can be written:

$$g_{ik}\frac{\mathrm{d}^2x^i}{\mathrm{d}s^2}+\Gamma_{ikj}\frac{\mathrm{d}x^i}{\mathrm{d}s}\frac{\mathrm{d}x^j}{\mathrm{d}s}=0 \tag{12.4.143}$$

The contracted multiplication (see section Tensor Calculus page 2038) of the preceding relation in the canonical basis by g^{kl} gives us:

$$g^{kl}g_{ik}\frac{\mathrm{d}^2x^i}{\mathrm{d}s^2}+g^{kl}\Gamma_{ikj}\frac{\mathrm{d}x^i}{\mathrm{d}s}\frac{\mathrm{d}x^j}{\mathrm{d}s}=\delta_{il}\frac{\mathrm{d}^2x^i}{\mathrm{d}s^2}+\Gamma^l_{ij}\frac{\mathrm{d}x^i}{\mathrm{d}s}\frac{\mathrm{d}x^j}{\mathrm{d}s}=0 \tag{12.4.144}$$

Hence:

$$\frac{\mathrm{d}^2x^i}{\mathrm{d}s^2}+\Gamma^l_{ij}\frac{\mathrm{d}x^i}{\mathrm{d}s}\frac{\mathrm{d}x^j}{\mathrm{d}s}=0 \tag{12.4.145}$$

In the literature a change of index is often carried out in order to finally get (it is still the same expression given that the indices have the same range of variation!):

$$\boxed{\frac{\mathrm{d}^2x^\mu}{\mathrm{d}s^2}+\Gamma^\mu_{\alpha\beta}\frac{\mathrm{d}x^\alpha}{\mathrm{d}s}\frac{\mathrm{d}x^\beta}{\mathrm{d}s}=0} \tag{12.4.146}$$

with $\Gamma^\mu_{\alpha\beta}$ being the Christoffel symbol of the second kind (see section Tensor Calculus page 2105) given by:

$$\Gamma^\mu_{\alpha\beta}=g^{\mu l}\Gamma_{\alpha\lambda\beta}=\frac{1}{2}g^{\mu\lambda}\left(\partial_\alpha g_{\lambda\beta}+\partial_\beta g_{\alpha\lambda}-\partial_\lambda g_{\alpha\beta}\right) \tag{12.4.147}$$

and is named in the context of General Relativity the "affine connection" or "connection coefficients" and which makes it possible to find the system of coordinates (through the resolution of a system of differential equations) in free fall in which the particle equation is that of a uniform movement in space-time as a function of a reference system (the two systems are therefore connected by the affine connection).

This relation, of the highest importance, allows us to determine how a moving body will naturally move in a curved space and this perhaps ... regardless of its mass !!! It therefore gives us the metric in which we must set a frame of reference so that it is inertial with respect to the body in question.

The previous equation of geodesics is also the differential equation of the second order which must therefore satisfy the parametric representation of a line on a surface where s is the length along the line so that its total length is extremal!!!

According to the principle of equivalence, we are therefore entitled to interpret this relation as the equation of motion in any gravitational field of and thus to interpret the second additional term of the equation as the opposite of a gravitational term force per unit mass, that is to say as the opposite of a gravitational field!

Remark

We can also write the equation of geodesics by using the proper time. Indeed:

$$\frac{\mathrm{d}^2x^\mu}{\left(\dfrac{\mathrm{d}\tau c}{\gamma}\right)^2}+\Gamma^\mu_{\alpha\beta}\frac{\mathrm{d}x^\alpha}{\left(\dfrac{\mathrm{d}\tau c}{\gamma}\right)}\frac{\mathrm{d}x^\beta}{\left(\dfrac{\mathrm{d}\tau c}{\gamma}\right)}=\frac{\mathrm{d}^2x^\mu}{\mathrm{d}\tau^2}+\Gamma^\mu_{\alpha\beta}\frac{\mathrm{d}x^\alpha}{\mathrm{d}\tau}\frac{\mathrm{d}x^\beta}{\mathrm{d}\tau}=0 \tag{12.4.148}$$

or by using the four-vector velocity:

$$\frac{\mathrm{d}u^\mu}{\mathrm{d}t}+\Gamma^\mu_{\alpha\beta}\mathrm{d}u^\alpha\mathrm{d}u^\beta=0 \tag{12.4.149}$$

Again, if we restrict ourselves to a flat space-time, we see trivially that we fall back on the first equation of motion that we had obtained since for the Minkowski metric $\eta_{\mu\nu}$ we have immediately $\Gamma^\mu_{\alpha\beta}=0$:

$$\frac{\mathrm{d}^2x^\mu}{\mathrm{d}s^2}+0\cdot\frac{\mathrm{d}x^\alpha}{\mathrm{d}s}\frac{\mathrm{d}x^\beta}{\mathrm{d}s}=\frac{\mathrm{d}^2x^\mu}{\mathrm{d}s^2}=\frac{\mathrm{d}^2x^\mu}{\left(\dfrac{\mathrm{d}\tau c^2}{\gamma}\right)^2}=\frac{\mathrm{d}^2x^\mu}{\mathrm{d}\tau^2}=0 \tag{12.4.150}$$

because the components of the Minkowski metric being constant the Christoffel coefficients are all zero.

The solutions of the latter equation are ordinary straight lines given by:

$$x^{\mu}(s)=a^{\mu}s-b^{\mu} \tag{12.4.151}$$

Obviously, in a general curved space-time, the geodesics can not be globally represented by straight lines. However, with a second-order approximation in Taylor's development (see section Sequences and Series), we fall back on straight lines (which is equivalent to bringing the curved space back to a flat space).

The important thing in all this is that the equation of geodesics makes it possible to observe that the curvature of space determines the trajectories of the bodies which move there whatever their mass, whether they are in uniform motion or not (observe the second derivative in the geodesic equation!). All that remains is then to complete the work and to relate the curvature of space-time with the energy that is there!

To fully understand the change of perspective with Newtonian Mechanics, consider yourself falling from a plane without a parachute. From the point of view of General Relativity, you do not undergo any force (!), you are not accelerating, you just follow the curvature of space-time. You follow your normal geodesic trajectory: your acceleration (in the sense of General Relativity!) is zero!

Now imagine lying on your bed. You are in a gravity field and yet you are not in a free fall. So you are not in the geodesic trajectory following the curvature of space-time. Indeed, you suffer a force that prevents you from following this path: the reaction force of your bed! From the point of view of the General Relativity, if you are static in a gravity field, you undergo an acceleration!

12.4.3.2 Newtonian Limit

We have shown above (Shild's argument) that to study gravitation (in particular the Einstein's effect), curved geometry is necessary. We promised also to show that it was enough. Now is the time to do it!

Definition (#12.4.544): The "Newtonian limit" is a physical situation where the three conditions below are satisfied:

C1. The particles move slowly with respect to the speed of light. This is expressed as the fact that the variations of the spatial components of their quadrivector are much less than those of the temporal component (t being the proper time):

$$\frac{\mathrm{d}x^i}{\mathrm{d}\tau}\ll\frac{\mathrm{d}x^0}{\mathrm{d}\tau} \tag{12.4.152}$$

C2. The gravitational field is static. In other words, any time derivative of the metric is zero!

C3. The gravitational field is weak, that is, it can be seen as a weak perturbation of a flat space:

$$g_{\mu\nu} \cong \eta_{\mu\nu} + h_{\mu\nu} \tag{12.4.153}$$

with $|h_{\mu\nu}| \ll 1$ and where $\eta_{\mu\nu}$ is constant (only $h_{\mu\nu}$ depends on the coordinates).

Let us consider the geodesic equation obtained previously:

$$\frac{\mathrm{d}^2 x^\mu}{\mathrm{d}\tau^2} + \Gamma^\mu_{\alpha\beta} \frac{\mathrm{d}x^\alpha}{\mathrm{d}\tau} \frac{\mathrm{d}x^\beta}{\mathrm{d}\tau} = 0 \tag{12.4.154}$$

The first condition (C1) leads us to simplify it in the form:

$$\frac{\mathrm{d}^2 x^\mu}{\mathrm{d}\tau^2} + \Gamma^\mu_{00} \left(\frac{\mathrm{d}x^0}{\mathrm{d}t} \right)^2 = 0 \tag{12.4.155}$$

Remark

The latter relation can often be found on various social networks written and rearranged as (...):

$$\frac{\mathrm{d}^2 r}{\mathrm{d}\tau^2} = -\Gamma^r_{tt} (u^t)^2 \tag{12.4.156}$$

and don't forget that the latter describes the acceleration in curved space time!

By the way... how do we describe using typical General Relativity notation the fact (for example) that we are at rest on the ground of Earth (i.e. the ground is opposing a force/acceleration against our free geodesic fall to Earth as the curvature $\Lambda^r_{tt} \neq 0$)? The answer is straightforward! We just have to add the classical Newton acceleration term such as:

$$\frac{\mathrm{d}^2 r}{\mathrm{d}\tau^2} = a^r - \Gamma^r_{tt} (u^t)^2 = \frac{F}{m} - \Gamma^r_{tt} (u^t)^2 \tag{12.4.157}$$

Therefore we can see that the left hand side to be zero needs the acceleration due to curvature to be compensate by another acceleration due to the reaction of the ground! Explicitly:

$$\frac{\mathrm{d}^2 r}{\mathrm{d}\tau^2} = 0 \Leftrightarrow a^r = \Gamma^r_{tt} (u^t)^2 \tag{12.4.158}$$

The two other conditions (C2 and C3 whose application has been shown in the development below) offer us several simplifications in the expression of the symbol of Christoffel of the second kind:

$$\begin{aligned}
\Gamma^\mu_{00} &= \frac{1}{2} g^{\mu\lambda} (\partial_0 g_{\lambda 0} + \partial_0 g_{0\lambda} - \partial_\lambda g_{00}) \\
&= -\frac{1}{2} g^{\mu\lambda} \partial_\lambda g_{00} \qquad \text{(C2)} \\
&\cong -\frac{1}{2} (\eta^{\mu\lambda} + h^{\mu\lambda}) \left(\underbrace{\partial_\lambda \eta_{00}}_{=0\,\text{(C3)}} + \partial_\lambda h_{00} \right) = -\frac{1}{2} (\eta^{\mu\lambda} + h^{\mu\lambda}) \partial_\lambda h_{00} \cong -\frac{1}{2} \eta^{\mu\lambda} \partial_\lambda h_{00}
\end{aligned} \tag{12.4.159}$$

The geodesic equation then becomes:

$$\frac{\mathrm{d}^2x^\mu}{\mathrm{d}\tau^2}-\frac{1}{2}\eta^{\mu\lambda}\partial_\lambda h_{00}\left(\frac{\mathrm{d}x^0}{\mathrm{d}\tau}\right)^2=0 \tag{12.4.160}$$

and is then equal for the temporal component to ($\mu=0$):

$$\frac{\mathrm{d}^2x^0}{\mathrm{d}\tau^2}-\frac{1}{2}\eta^{0\lambda}\partial_\lambda h_{00}\left(\frac{\mathrm{d}x^0}{\mathrm{d}\tau}\right)^2=0 \tag{12.4.161}$$

But (recall of the Minkowski metric):

$$\eta^{0\lambda}=0 \tag{12.4.162}$$

for $\lambda>0$ and for $\lambda=0$ we have (static metric):

$$\partial_0 h_{00}=0 \tag{12.4.163}$$

Therefore, we must conclude that $\mathrm{d}x^0/\mathrm{d}t$ is a constant (whatever the choice of the signature of the Minkowski metric).

And for the spatial components, we know that $\eta^{\mu\nu}$ when reduced to its spatial part is a simple unitary 3×3 matrix, which gives for each spatial component in the case where we choose (by tradition only!) the signature $(-,+,+,+)$ of the Minkowski metric:

$$\frac{\mathrm{d}^2x^i}{\mathrm{d}\tau^2}-\frac{1}{2}\partial_i h_{00}\left(\frac{\mathrm{d}x^0}{\mathrm{d}\tau}\right)^2=0 \tag{12.4.164}$$

Obviously, the reader can have fun making the development that follows with the inverse signature $(+,-,-,-)$ and he will see that it only changes the sign of potential in the final result of the development): Let us now rearrange the above relation:

$$\frac{\mathrm{d}^2x^i}{\mathrm{d}\tau^2}=\frac{1}{2}\partial_i h_{00}\left(\frac{\mathrm{d}x^0}{\mathrm{d}\tau}\right)^2=0 \tag{12.4.165}$$

By dividing by $(\mathrm{d}x^0/\mathrm{d}\tau)^2$ and restoring $x^0=c\tau$, we get by making as sequence of simplifications:

$$\begin{aligned}\frac{\mathrm{d}x^i}{\mathrm{d}\tau^2}\left(\frac{\mathrm{d}\tau}{\mathrm{d}x^0}\right)^2&=\frac{1}{2}\partial_i h_{00}\\ \frac{\mathrm{d}^2x^i}{(\mathrm{d}x^0)^2}&=\frac{1}{2}\partial_i h_{00}\\ \frac{\mathrm{d}^2x^i}{(\mathrm{d}c\tau)^2}&=\frac{1}{2}\partial_i h_{00}\\ \frac{\mathrm{d}^2x^i}{\mathrm{d}\tau^2}&=\frac{c^2}{2}\partial_i h_{00}\end{aligned} \tag{12.4.166}$$

Starting from here we put (because our illustrious predecessors have tried before us):

$$h_{00}=-\frac{2}{c^2}\varphi=-\frac{2GM}{rc^2} \tag{12.4.167}$$

such as (a relation which will be very useful to us when studying the Schwarzschild metric further below):

$$g_{00}=\eta_{00}+h_{00}=1-\frac{2}{c^2}\varphi=1-\frac{2GM}{rc^2} \qquad (12.4.168)$$

where φ is the gravitational potential. We fall back here on the expression of the gravitational acceleration (Newton-Poisson equation) of the Newtonian mechanics (see section Astronomy page 5267):

$$\vec{a}=\frac{\mathrm{d}^2x^i}{\mathrm{d}t^2}=-\frac{c^2}{2}\partial_i\left(\frac{2\varphi}{c^2}\right)=-\partial_i\varphi=-\vec{\nabla}\varphi \qquad (12.4.169)$$

with $i=1,2,3$.

Remark

That last equality and analogy for the Newton-Poisson equation may not be obvious for some readers. So another direct analogy (and at the same time a more general result) will be given at the page 5778 using the general Einstein's field equations (i.e. with the cosmological constant)!

This development, simple but nevertheless remarkable by its interpretation, proves that the curved geometry is sufficient to describe the gravitation (and therefore the theory of Newton)!!!!!!!!!!!! This verification is named by some people the "principle of correspondence".

Demonstrating that a new theory reproduces all the achievements of successful old theories can be extremely difficult. This is because a new theory might use an entirely different mathematical framework that looks nothing like that of the old theory. Finding a way to show that both nevertheless arrive at the same predictions for already-made observations often requires finding a suitable way to reformulate the new theory. This is straightforward in cases where the new theory directly employs the math of the old one, but it can be a big hurdle with entirely new frameworks.

Einstein, for example, struggled for years to prove that General Relativity, his new theory of gravity, would reproduce the successes of the predecessor, Newtonian gravity. The problem wasn't that he had the wrong theory; the problem was that he didn't know how to find Newton's gravitational potential in his own theory. Einstein had all the math right, but the identification with the real world was missing. Only after several wrong attempts did he hit on the right way to do it. Having the right math is only part of having the right theory!

12.4.4 Stress-Energy Tensor

The "Stress-Energy Tensor (SET)" (sometimes named "stress–energy–momentum tensor" or "energy–momentum tensor") is a mathematical tool used (in particular) in General Relativity to represent the density and flux of energy and moment in space-time, generalizing the stress tensor of Newtonian physics of mass and energy. It is therefore an attribute of matter, radiation, and non-gravitational force fields. The stress–energy tensor is the source of the gravitational field in the Einstein's field equations of General Relativity, just as mass density is the source of such a field in Newtonian gravity[45].

Let us take for example the SET which considers matter in General Relativity as being able to be approximated by a perfect fluid. In the section Continuum Mechanics we have proved:

$$N_i=\sigma_{ij}n_j \tag{12.4.170}$$

where N_i has for recall the units of a force and n_j those of a surface. Thus with a more conventional writing:

$$F_i=\sigma_{ij}n_j \tag{12.4.171}$$

In variational form this gives:

$$\sigma_{ij}=\left.\frac{\Delta F_i}{\Delta n_j}\right|_{\Delta a_j\rightarrow 0} \tag{12.4.172}$$

Let us now calculate:

$$\sigma_{ij}=\frac{\Delta F_i}{\Delta n_j}=\frac{\Delta(ma_i)}{\Delta n_j}=\frac{\Delta(\rho Va_i)}{\Delta n_j} \tag{12.4.173}$$

Remark

We do not work with differential elements to avoid being trapped later. It is completely a physicist Do It Yourself approach, but it works well (confirmed by experience...).

Assuming that only the volume and the time makes that the force varies (which assume a constant density and the to be inertial) we then have:

$$\begin{aligned}\sigma_{ij}&=\frac{\Delta(\rho Va_i)}{\Delta n_j}=\frac{1}{\Delta n_j}\Delta\left(\frac{V}{t}\right)\rho v_i=\frac{1}{\Delta n_j}\frac{\Delta V}{\Delta t}\rho v_i=\frac{\Delta x_i\Delta x_j\Delta x_k}{\Delta n_j}\rho\frac{v_i}{\Delta t}\\&=\frac{\Delta x_i\Delta x_j\Delta x_k}{\Delta x_i\Delta x_k}\rho\frac{v_i}{\Delta t}=\frac{\Delta x_j}{\Delta t}\rho v_i=v_j\rho v_i=\rho v_j v_i\end{aligned} \tag{12.4.174}$$

This gives simply the tensor product of the velocities (see section Tensor Calculus page 2073):

$$\vec{\sigma}=\rho\vec{v}\otimes\vec{v} \tag{12.4.175}$$

If we generalize this relation to the velocity quadrivectors of Special Relativity with the corresponding notations, then we have by definition the "energy-momentum tensor" or "Stress–energy tensor":

$$\vec{T}=\rho\vec{u}\otimes\vec{u} \tag{12.4.176}$$

or in index form:

$$T_{ij}=\rho u_i u_j \tag{12.4.177}$$

---

[45] The gravitational field is a thing, but it's not an en "energy field"! Indeed, a field is one thing; energy is something it can have. But again, as far as we know, there is no such thing as an "energy field"!

Either in contravariant form (most common form in textbooks):

$$\boxed{T^{ij}=\rho u^i u^j} \tag{12.4.178}$$

This relation is the justification for which General Relativity is also indicated as a theory of continuous mechanics by some specialists.

Now let us prove the following equality of the derivative:

$$\partial_j T^{0j}=\partial_j(\rho u^0 u^j)=0 \tag{12.4.179}$$

Remark

What we have already pointed out in the section of Tensorial Calculus is written $T^{0j}_{,j}$ in old books or in modern textbooks where the author want to show its technical level...

First, let us recall that (see section Special Relativity page 5642):

$$u^\nu=(u^0,u^1,u^2,u^3)=\gamma(\vec{v})(c,v^1,v^2,v^3)=\gamma(\vec{v})(c,v^x,v^y,v^z) \tag{12.4.180}$$

and let us admit that we are in low speeds such as $\gamma=1$. Then, in a Minkowski metric of type $(+,-,-,-)$ we have:

$$\begin{aligned}\partial_j T^{0j}&=\partial_j(\rho u^0 u^j)=\partial_j(\rho c u^j)\\&=\partial_0(\rho c u^0)+\partial_1(\rho c u^1)+\partial_2(\rho c u^2)+\partial_3(\rho c u^3)\\&=\frac{\partial(\rho c c)}{\partial c t}-\frac{\partial(\rho c v^x)}{\partial x}-\frac{\rho c v^y}{\partial y}-\frac{\rho c v^z}{\partial z}\\&=c\left(\frac{\partial\rho}{\partial t}-\frac{\partial(\rho v^x)}{\partial x}-\frac{\partial(\rho v^y)}{\partial y}-\frac{\partial(\rho v^z)}{\partial z}\right)\\&=c\left(\frac{\partial\rho}{\partial t}-\vec{\nabla}\circ(\rho\vec{v})\right)\end{aligned} \tag{12.4.181}$$

But, we recognize in the parentheses the equation of continuity (conservation of the mass) which we have proved in the section of Thermodynamics (see page 3679) and which we know is equal to zero in a system without sources! Therefore:

$$\partial_j T^{0j}=c\left(\frac{\partial\rho}{\partial t}-\vec{\nabla}\circ(\rho\vec{v})\right)=c\cdot 0=0 \tag{12.4.182}$$

Let us also look to what contains the component T^{00} of the stress-energy tensor:

$$T^{00}=\rho u^0 u^0=\rho\gamma c\gamma c=c^2\gamma^2\rho \tag{12.4.183}$$

In terms of units, this is an energy density (we see directly that this quantity can only be positive).

Let us now look at the other components with $i=0$ and $j=1,2,3$:

$$T^{0j}=\rho u^0 u^j=\rho(\gamma c)(\gamma v^j)=c\rho\gamma^2 v^j=cp^i \tag{12.4.184}$$

where p^i has the units of linear momentum density.

Let us now consider the components of the tensor when $i,j=1\ldots3$ (we omit then the first row and the first column):

$$T^{ij}=\rho(\gamma u^i)(\gamma u^j)=\rho\gamma^2u^iu^j=\sigma_{ij} \tag{12.4.185}$$

We thus fall back on the components of the stress tensor of a perfect fluid.

So finally, the stress-energy tensor can be written in the form of a symmetric real 4×4 matrix:

$$\boxed{T^{ij}=\begin{bmatrix}T^{00}&T^{01}&T^{02}&T^{03}\\T^{10}&T^{11}&T^{12}&T^{13}\\T^{20}&T^{21}&T^{22}&T^{23}\\T^{30}&T^{31}&T^{32}&T^{33}\end{bmatrix}=\begin{bmatrix}\rho\gamma^2c^2&\rho\gamma^2cv^x&\rho\gamma^2cv^y&\rho\gamma^2cv^z\\\rho\gamma^2cv^x&\rho\gamma^2v^xv^x&\rho\gamma^2v^xv^y&\rho\gamma^2v^xv^z\\\rho\gamma^2cv^y&\rho\gamma^2v^yv^x&\rho\gamma^2v^yv^y&\rho\gamma^2v^yv^z\\\rho\gamma^2cv^z&\rho\gamma^2v^zv^x&\rho\gamma^2v^zv^y&\rho\gamma^2v^zv^z\end{bmatrix}} \tag{12.4.186}$$

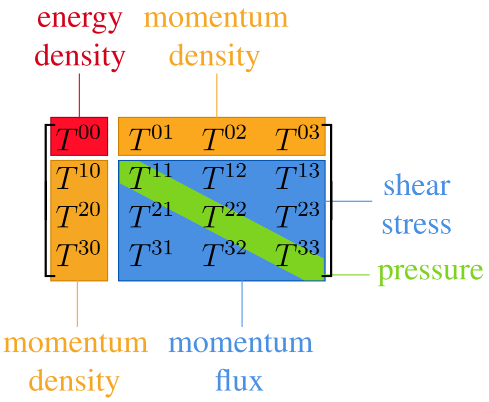
In the case where the velocities are small, i.e. $\gamma\rightarrow 1$, we have:

$$\begin{aligned}T^{ij}&=\begin{bmatrix}\rho c^2&\rho cv^x&\rho cv^y&\rho cv^z\\\rho cv^x&\rho v^xv^x&\rho v^xv^y&\rho v^xv^z\\\rho cv^y&\rho v^yv^x&\rho v^yv^y&\rho v^yv^z\\\rho cv^z&\rho v^zv^x&\rho v^zv^y&\rho v^zv^z\end{bmatrix}=\begin{bmatrix}\dfrac{mc^2}{V}&\rho cv^x&\rho cv^y&\rho cv^z\\\rho cv^x&\sigma_{xx}&\tau^{xy}&\tau^{xz}\\\rho cv^y&\tau^{yz}&\sigma_{yy}&\tau^{yz}\\\rho cv^z&\tau^{zx}&\tau^{zy}&\sigma_{zz}\end{bmatrix}\\&=\begin{bmatrix}\dfrac{E_{\text{tot}}}{V}&\rho cv^x&\rho cv^y&\rho cv^z\\\rho cv^x&\sigma_{xx}&\tau^{xy}&\tau^{xz}\\\rho cv^y&\tau^{yz}&\sigma_{yy}&\tau^{yz}\\\rho cv^z&\tau^{zx}&\tau^{zy}&\sigma_{zz}\end{bmatrix}\end{aligned} \tag{12.4.187}$$

This tensor is also sometimes represented as following:

$$\begin{aligned}T^{\mu\nu}&=\left(\begin{array}{c|ccc}T^{00}&T^{01}&T^{02}&T^{03}\\\hline T^{10}&T^{11}&T^{12}&T^{13}\\T^{20}&T^{21}&T^{22}&T^{23}\\T^{30}&T^{31}&T^{32}&T^{33}\end{array}\right)=\left(\begin{array}{c|c}T^{00}&T^{0i}\\\hline T^{i0}&T^{ij}\end{array}\right)\\&=\left(\begin{array}{c|c}\text{energy density}&\text{component } i \text{ of momentum density}\\\hline\text{component } i \text{ of momentum density}&\text{flux in } j \text{ direction of momentum component } i\end{array}\right)\end{aligned} \tag{12.4.188}$$

We thus fall back in this tensor on the following interpretations of the physical quantities (although rigorously all the components have units which can be seen as density of energy or as a pressure):



energy density
momentum density
T^{00} T^{01} T^{02} T^{03}
T^{10} T^{11} T^{12} T^{13}
T^{20} T^{21} T^{22} T^{23}
T^{30} T^{31} T^{32} T^{33}
shear stress
pressure
momentum density
momentum flux

There is another nice and interesting way to get the momentum-flux part of that tensor.

First let us recall the Euler equation of the 1st form that we get in the section of Continuum Mechanics at page 3828 (p is the pressure and not the linear momentum density!):

$$\rho \mathrm{d}_t\vec{v}=-\vec{\nabla}p+\rho\vec{f} \tag{12.4.189}$$

or more explicitly using the material derivative:

$$\rho\partial_t\vec{v}+\rho(\vec{v}\circ\vec{\nabla})\vec{v}=-\vec{\nabla}p+\rho\vec{f} \tag{12.4.190}$$

where for recall $\vec{f}=-\vec{\nabla}U$.

Let us assume that $\vec{f}=-\vec{\nabla}U=\vec{0}$. Therefore the latter equation can is reduced to:

$$\partial_t\vec{v}+(\vec{v}\circ\vec{\nabla})\vec{v}=-\frac{1}{\rho}\vec{\nabla}p \tag{12.4.191}$$

and explicitly to (for $i,k=1,2,3$):

$$\frac{\partial v^i}{\partial t}+v^k\frac{\partial v^i}{\partial x^k}=-\frac{1}{\rho}\frac{\partial p}{\partial x^i}=-\frac{1}{\rho}\delta_{ik}\frac{\partial p}{\partial x^k} \tag{12.4.192}$$

Hence:

$$\frac{\partial v^i}{\partial t}=-v^k\frac{\partial v^i}{\partial x^k}-\frac{1}{\rho}\delta_{ik}\frac{\partial p}{\partial x^k} \tag{12.4.193}$$

Now let us recall the equation of mass conservation (see section Continuum Mechanics page 3683):

$$\partial_t\rho+\vec{\nabla}\circ(\rho\vec{v})=0 \tag{12.4.194}$$

That we will rearrange and rewrite:

$$\frac{\partial\rho}{\partial t}=-\vec{\nabla}\circ(\rho\vec{v})=-\frac{-\partial(\rho v^k)}{\partial x^k} \tag{12.4.195}$$

But we also have:

$$\frac{\partial(\rho v^i)}{\partial t}=v^i\frac{\partial\rho}{\partial t}+\rho\frac{\partial v^i}{\partial t} \tag{12.4.196}$$

By injecting in that latter relation the mass conservation equation and the expression we got for $\partial_t v_i$ we then have:

$$\frac{\partial(\rho v^i)}{\partial t}=-v^i\frac{\partial v^i}{\partial x^k}-\rho v^k\frac{\partial v^i}{\partial v^k}-\delta_{ik}\frac{\partial p}{\partial x^k}=-\frac{\partial(\rho v^i v^k)}{\partial x^k}-\delta_{ik}\frac{\partial p}{\partial x^k}=-\frac{\partial(\rho v^i v^k+\delta_{ik}p)}{\partial x^k} \tag{12.4.197}$$

Therefore:

$$\frac{\partial(\rho v^i)}{\partial t}=-\text{div}(\rho v^i v^k+\delta_{ik}p) \tag{12.4.198}$$

It appears between the parenthesis a more general notation of the energy-stress tensor for $i,k=1,2,3$, that is the moment flux part:

$$T^{ik}=\rho v^i v^k+\delta_{ik}p \tag{12.4.199}$$

We then understand better why this matrix is named "Energy-Momentum Tensor" or "Stress-Energy-Momentum Tensor" since implicitly it is a question of modelling the space by a perfect fluid under shear stresses (tangential forces) and tensions (normal forces).

Remark

The sub-matrix of spatial components:

$$T^{ij}=\begin{bmatrix} T^{11} & T^{12} & T^{13} \\ T^{21} & T^{22} & T^{23} \\ T^{31} & T^{32} & T^{33} \end{bmatrix} \tag{12.4.200}$$

is the matrix named the "matrix of moments flows" (a name that is quite debatable ...). In Continuum Mechanics (see section of the same name page 3811), we have proved that its diagonal corresponds to the pressure, and the other components to the tangential forces due to the dynamic viscosity.

Let us prove that the covariant derivative (see section Tensor Calculus page 2113) of the stress-energy tensor is zero such that:

$$\nabla_\mu T^{\mu\nu}=0 \tag{12.4.201}$$

Therefore:

$$\nabla_\mu T^{\mu\nu}=\nabla_\mu(\rho u^\mu u^\nu)=u^\nu\nabla_\mu(\rho u^\mu)+\rho u^\mu\nabla_\mu(u^\nu) \tag{12.4.202}$$

Let us begin by developing the first term:

$$u^\nu\nabla_\mu(\rho u^\mu)=u^\nu\left(\frac{\partial(\rho\gamma c)}{\partial ct}-\frac{\partial(\rho\gamma u^x)}{\partial x}-\frac{\partial(\rho\gamma u^x)}{\partial x}-\frac{\partial(\rho\gamma u^y)}{\partial x}-\frac{\partial(\rho\gamma u^z)}{\partial z}\right) \tag{12.4.203}$$

But we have:

$$\frac{\partial\gamma}{\partial x}=\frac{\partial\gamma}{\partial y}=\frac{\partial\gamma}{\partial z}=0 \tag{12.4.204}$$

hence:

$$u^\nu\nabla_\mu(\rho u^\mu)=u^\nu\left(\frac{\partial(\rho\gamma)}{\partial t}-\gamma\vec{\nabla}\circ(\rho\vec{u})\right)=u^\nu\left(\rho\frac{\partial\gamma}{\partial t}+\gamma\left[\frac{\partial(\rho)}{\partial t}-\vec{\nabla}\circ(\rho\vec{u})\right]\right) \tag{12.4.205}$$

We find in the squared brackets the equation of continuity which is zero in the absence of sources. On the other hand, the first term in parentheses is non-zero as we saw in our study of the four-accelerator acceleration in the section of Special Relativity:

$$u^\nu\nabla_\mu(\rho u^\mu)=u^\nu\rho\frac{\partial\gamma}{\partial t}=u^\nu\rho\left(\frac{\gamma^3}{c^2}\vec{v}\circ\vec{v}\right) \tag{12.4.206}$$

But according to the weak principle of equivalence (WPE), we can always place ourselves in a repository such that locally the acceleration is null, that is to say such that (for recall, we do not put vector arrows for the quadrivectors):

$$a=0 \tag{12.4.207}$$

And it comes then:

$$u^\nu\nabla_\mu(\rho u^\mu)=0 \tag{12.4.208}$$

So we now have:

$$\nabla_\mu T^{\mu\nu}=u^\nu\nabla_\mu(\rho u^\mu)+\rho u^\mu\nabla_\mu(u^\nu)=0+\rho u^\mu\nabla_\mu(u^v)=\rho u^\mu\nabla_\mu(u^\nu) \tag{12.4.209}$$

Let us look at what this last term gives but first recalling that in the section of Special Relativity we had proved that the quadri-acceleration was expressed according to:

$$a^\nu=\left(\frac{\gamma^4}{c}\vec{v}\circ\vec{a},\gamma^2\vec{a}+\frac{\gamma^4}{c^2}(\vec{v}\circ\vec{a})\vec{v}\right) \tag{12.4.210}$$

Therefore (we take only the first two components as examples):

$$\begin{aligned}a^0&=\frac{\gamma^4}{c}(v^xa^x+v^ya^y+v^za^z)\\a^1&=\gamma^2a^x+\frac{\gamma^4}{c^2}(v^xa^x+v^ya^y+v^za^z)v^x\\&\ldots\end{aligned} \tag{12.4.211}$$

We will now in fact prove that:

$$u^\mu\nabla_\mu(u^\nu)=a^\nu \tag{12.4.212}$$

For this we start first by proving that:

$$u^\mu\nabla_\mu(u^0)=a^0 \tag{12.4.213}$$

For this we calculate first:

$$u^\mu\nabla_\mu(u^0)=\gamma c\frac{\partial(\gamma c)}{\partial(ct)}+\gamma v^x\frac{\partial(\gamma c)}{\partial x}+\gamma v^y\frac{\partial(\gamma c)}{\partial y}+\gamma v^z\frac{\partial(\gamma c)}{\partial z} \tag{12.4.214}$$

But:

$$\frac{\partial\gamma}{\partial x}=\frac{\partial\gamma}{\partial y}=\frac{\partial\gamma}{\partial z}=0\qquad\text{and}\qquad\frac{\partial c}{\partial x}=\frac{\partial c}{\partial y}=\frac{\partial c}{\partial z}=0 \tag{12.4.215}$$

Therefore:

$$u^\mu\nabla_\mu(u^0)=\gamma c\frac{\partial(\gamma c)}{\partial(ct)}=\gamma c\frac{\partial\gamma}{\partial t}=\gamma c\left(\frac{\gamma^3}{c^2}\vec{v}\circ\vec{a}\right)=\frac{\gamma^4}{c}\vec{v}\circ\vec{a}=a^0 \tag{12.4.216}$$

Now let us prove that:

$$u^\mu\nabla_\mu(u^1)=a^1 \tag{12.4.217}$$

the other components a^2, a^3 are then verified automatically.

For this we do a little bit of algebra:

$$\begin{aligned}u^\mu\nabla_\mu(u^1)&=\gamma c\frac{\partial(\gamma v^x)}{\partial(ct)}+\underbrace{\gamma v^x\frac{\partial(\gamma v^x)}{\partial x}+\gamma v^y\frac{\partial(\gamma v^x)}{\partial y}+\gamma v^z\frac{\partial(\gamma v^x)}{\partial z}}_{=0}\\&=\gamma\frac{\partial(\gamma v^x)}{\partial t}=\gamma\left(v^2\frac{\partial\gamma}{\partial t}+\gamma\frac{\partial v^x}{\partial t}\right)=\gamma\left(v^x\left(\frac{\gamma^3}{c^2}\vec{v}\circ\vec{a}\right)+\gamma a^x\right)\\&=\gamma^2a^x+\left(\frac{\gamma^4}{c^2}\vec{v}\circ\vec{a}\right)v^x=a^1\end{aligned} \tag{12.4.218}$$

and therefore we have indeed:

$$u^{\mu}\nabla_{\mu}(u^{\nu})=a^{\nu} \tag{12.4.219}$$

but according to the WEP (Weak Equivalence Principle[46]), $a^{\nu}=0$ therefore:

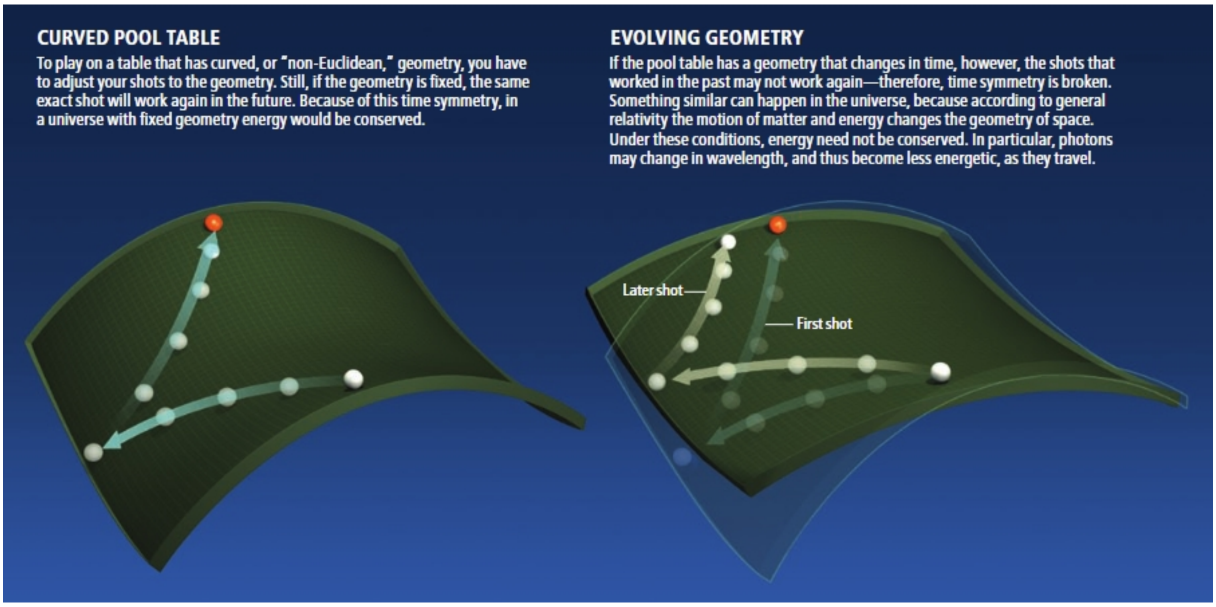
$$u^{\mu}\nabla_{\mu}(u^{\nu})=0 \tag{12.4.220}$$

and finally we have indeed under the assumptions stated above:

$$\boxed{\nabla_{\mu}T^{\mu\nu}=0} \tag{12.4.221}$$

Which is the expression of the conservation of energy in General Relativity (because the components that are energy and momentum are conserved quantities)!

The meaning of this equation is straightforward enough: energy and momentum evolve in a precisely specified way in response to the behaviour of space-time around them. If that space-time is standing completely still, the total energy is constant; if it's evolving, the energy changes in a completely unambiguous way!



CURVED POOL TABLE

To play on a table that has curved, or "non-Euclidean," geometry, you have to adjust your shots to the geometry. Still, if the geometry is fixed, the same exact shot will work again in the future. Because of this time symmetry, in a universe with fixed geometry energy would be conserved.

EVOLVING GEOMETRY

If the pool table has a geometry that changes in time, however, the shots that worked in the past may not work again—therefore, time symmetry is broken. Something similar can happen in the universe, because according to general relativity the motion of matter and energy changes the geometry of space. Under these conditions, energy need not be conserved. In particular, photons may change in wavelength, and thus become less energetic, as they travel.

By lowering the indices it comes:

$$\nabla^{\rho}T_{\rho\sigma}=g^{\rho\mu}\nabla_{\rho}\left(g_{\rho\mu}g_{\sigma\nu}T^{\rho\sigma}\right)=\nabla_{\mu}T^{\mu\nu}=0 \tag{12.4.222}$$

---

[46] For reminder it states that all free-falling test particles fall with the same acceleration in a gravitational field, regardless of their mass or internal composition

12.4.4.1 Stress-Energy Tensor for a perfect fluid

In physics, a perfect fluid is a fluid that can be completely characterized by its rest frame mass density ρ isotropic pressure p.

Real fluids are "sticky" and contain (and conduct) heat. Perfect fluids are idealized models in which these possibilities are neglected. Specifically, perfect fluids have no shear stresses, viscosity, or heat conduction.

According to these properties, if we rewrite the stress-energy tensor:

$$T^{ij}=\begin{bmatrix}\dfrac{E_{\text{tot}}}{V} & \rho c v^x & \rho c v^y & \rho c v^z\\ \rho c v^x & \rho v^x v^x & \rho v^x v^y & \rho v^x v^z\\ \rho c v^y & \rho v^y v^z & \rho v^y v^y & \rho v^y v^z\\ \rho c v^z & \rho v^z v^x & \rho v^z v^y & \rho v^y v^z\end{bmatrix}=\begin{bmatrix}\dfrac{E_{\text{tot}}}{V} & \rho c v^x & \rho c v^y & \rho c v^z\\ \rho c v^x & \sigma_{xx} & \tau^{xy} & \tau^{xz}\\ \rho c v^y & \tau^{yz} & \sigma_{yy} & \tau^{yz}\\ \rho c v^z & \tau^{zx} & \tau^{zy} & \sigma_{zz}\end{bmatrix}\tag{12.4.223}$$

as:

$$T^{ij}=\begin{bmatrix}\rho c^2 & \rho c v^x & \rho c v^y & \rho c v^z\\ \rho c v^x & P & \tau^{xy} & \tau^{xz}\\ \rho c v^y & \tau^{yz} & P & \tau^{yz}\\ \rho c v^z & \tau^{zx} & \tau^{zy} & P\end{bmatrix}\tag{12.4.224}$$

Form the definition of the perfect fluid, especially the no heat conduction, we have immediately that:

$$T^{01}=T^{02}=T^{03}=T^{10}=T^{20}=T^{30}=0\tag{12.4.225}$$

Indeed, energy can flow only if particles flow. So if there is not heat conduction, there is no particle flow and therefore no momentum density.

If there is no viscosity we have also obviously all τ_{ij} that are zero.

Therefore so far we have:

$$T^{ij}=\begin{bmatrix}\rho c^2 & 0 & 0 & 0\\ 0 & P & 0 & 0\\ 0 & 0 & P & 0\\ 0 & 0 & 0 & P\end{bmatrix}\tag{12.4.226}$$

But this can be written:

$$\boxed{T^{ij}=\left(\rho+\frac{P}{c^2}\right)u^i u^j-P\eta^{ij}}\tag{12.4.227}$$

where we choose the signature $(+,-,-,-)$ with for recall:

$$u^\nu=\gamma(c,v^x,v^y,v^z)\tag{12.4.228}$$

and where we assume for the perfect fluid that $\gamma\rightarrow 1$ and that we are in the local rest frame such as:

$$u^\nu=(c,0,0,0)\tag{12.4.229}$$

As in many cases we consider weak static gravitational field, then it is common to write the previous boxed relation:

$$\boxed{T^{ij} \cong \left(\rho+\frac{P}{c^2}\right)u^i u^j - Pg^{ij}} \tag{12.4.230}$$

Perfect fluids are often used in General Relativity to model idealized distributions of matter, such as the interior of a star or an isotropic universe. In the latter case, the equation of state of the perfect fluid may be used in Friedmann–Lemaître–Robertson–Walker equations to describe the evolution of our Universe as we will see it in the next section.

12.4.4.2 Electromagnetic stress–energy tensor

In relativistic physics, the electromagnetic stress–energy tensor is the contribution to the stress–energy tensor due to the electromagnetic field. The stress–energy tensor describes the flow of energy and momentum in space-time. The electromagnetic stress–energy tensor contains the classical Maxwell stress tensor that governs the electromagnetic interactions.

Let us recall first that in the section of Electrodynamics (see section Electrodynamics page 4156) we have proved the energy density carried by an electrodynamic wave was:

$$u_{\text{tot}} = \frac{1}{2}\varepsilon\hat{E}^2 + \frac{1}{2\mu}\hat{B}^2 = \frac{1}{2}\varepsilon\hat{E}^2 + \frac{1}{2\mu c^2}\hat{E}^2 = \varepsilon\hat{E}^2 = \frac{1}{\mu}\hat{B}^2 \tag{12.4.231}$$

And also that (see section Electrodynamics page 4135):

$$(g_{\mu\sigma}g_{\nu\rho}F^{\sigma\rho})F^{\mu\nu} = F_{\mu\nu}F^{\mu\nu} = 2\left(c^2\|\vec{B}\|^2 - \|\vec{E}\|^2\right) \tag{12.4.232}$$

and that (see section Electrodynamics page 4128):

$$E^k = F^{ik}u^k \tag{12.4.233}$$

Ok now that we have the necessary tools let's go!

From the previous relation, we get:

$$\|\vec{E}^2\| = \frac{1}{c^2}F_{\beta\alpha}u^\alpha F_\gamma^\beta u^\gamma = \frac{1}{c^2}F_{\beta\alpha}u^\alpha(g_{\gamma\sigma}F^{\beta\sigma})u^\gamma \tag{12.4.234}$$

and for the remaining part of the development will take the metric $\eta_{\gamma\sigma}$. Then:

$$\|\vec{E}^2\| = F_{\beta\alpha}u^\alpha\left(\eta_{\gamma 1}F^{\beta 1} + \eta_{\gamma 2}F^{\beta 2} + \eta_{\gamma 3}F^{\beta 3} + \eta_{\gamma 4}F^{\beta 4}\right)u^\gamma \tag{12.4.235}$$

As in an inertial frame in which it is at rest where the four-velocity is $u^\gamma = (c,0,0,0)$, we have then to focus only on $\gamma = 1$. Therefore:

$$\|\vec{E}^2\| = F_{\beta\alpha}u^\alpha\left(\eta_{11}F^{\beta 1} + \eta_{12}F^{\beta 2} + \eta_{13}F^{\beta 3} + \eta_{14}F^{\beta 4}\right)c = -cF_{\beta\alpha}u^\alpha F^{\beta 1} \tag{12.4.236}$$

As in an inertial frame in which it is at rest where the four-velocity is $u^\alpha = (c,0,0,0)$, we have then to focus only on $\alpha = 1$. Therefore:

$$\begin{aligned}\|\vec{E}^2\| &= -c^2F_{\beta 1}F^{\beta 1} = -c^2\left(F_{11}F^{11} + F_{21}F^{21} + F_{31}F^{31} + F_{41}F^{41}\right)\\ &= -c^2(0\cdot 0 + (-E_x)E_x + (-E_y)E_y + (-E_z)E_z) = E_x^2 + E_y^2 + E_z^2\end{aligned} \tag{12.4.237}$$

Furthermore, as:

$$F_{\alpha\beta}F^{\alpha\beta}=2\left(c^2\|\vec{B}\|^2-\|\vec{E}\|^2\right) \tag{12.4.238}$$

We have:

$$c^2\|\vec{B}\|^2=\frac{1}{2}F_{\alpha\beta}F^{\alpha\beta}+\|\vec{E}\|^2=\frac{1}{2}F_{\alpha\beta}F^{\alpha\beta}+\frac{1}{c^2}F_{\beta\alpha}u^\alpha F_\gamma^\beta u^\gamma \tag{12.4.239}$$

So we have so far:

$$\begin{aligned}\|\vec{E}\|^2&=\frac{1}{c^2}F_{\beta\alpha}u^\alpha F_\gamma^\beta u^\gamma\\ c^2\|\vec{B}\|^2&=\frac{1}{2}F_{\alpha\beta}F^{\alpha\beta}+\frac{1}{c^2}F_{\beta\alpha}u^\alpha F_\gamma^\beta u^\gamma\end{aligned} \tag{12.4.240}$$

Putting these together in :

$$u_{\text{tot}}=\frac{1}{2}\varepsilon\hat{E}^2+\frac{1}{2\mu}\hat{B}^2=\frac{\varepsilon}{2}\left(\hat{E}^2+\frac{1}{\mu\varepsilon}\hat{B}^2\right)=\frac{\varepsilon}{2}\left(\hat{E}^2+c^2\hat{B}^2\right) \tag{12.4.241}$$

Then:

$$u_{\text{tot}}=\frac{\varepsilon}{2}\left(\frac{1}{c^2}F_{\beta\alpha}u^\alpha F_\gamma^\beta u^\gamma+\left(\frac{1}{2}F_{\alpha\beta}F^{\alpha\beta}+\frac{1}{c^2}F_{\beta\alpha}u^\alpha F_\gamma^\beta u^\gamma\right)\right)=\varepsilon\left(\frac{1}{c^2}F_{\beta\alpha}u^\alpha F_\gamma^\beta u^\gamma+\frac{1}{4}F_{\alpha\beta}F^{\alpha\beta}\right) \tag{12.4.242}$$

Putting these together, and inserting a factor of :

$$-g_{\alpha\gamma}u^\alpha u^\gamma=c^2\Leftrightarrow-\frac{g_{\alpha\gamma}}{c^2}u^\alpha u^\gamma=1 \tag{12.4.243}$$

gives the energy density:

$$\begin{aligned}u_{\text{tot}}&=\varepsilon\left(\frac{1}{c^2}F_{\beta\alpha}u^\alpha F_\gamma^\beta u^\gamma-\frac{1}{4}\frac{g_{\alpha\gamma}}{c^2}u^\alpha u^\gamma F_{\alpha\beta}F^{\alpha\beta}\right)=\frac{\varepsilon}{c^2}\left(F_{\beta\alpha}F_\gamma^\beta-\frac{1}{4}g_{\alpha\gamma}F_{\alpha\beta}F^{\alpha\beta}\right)u^\alpha u^\gamma\\ &=\frac{1}{\mu}\left(F_{\beta\alpha}F_\gamma^\beta-\frac{1}{4}g_{\alpha\gamma}F_{\alpha\beta}F^{\alpha\beta}\right)u^\alpha u^\gamma\end{aligned} \tag{12.4.244}$$

Since in general as we have seen just above $u_{\text{tot}}=T_{\alpha\beta}u^\alpha u^\beta$ then the above relation can hold for all rest frames only if:

$$\boxed{T_{\alpha\gamma}=\frac{1}{\mu}\left(F_{\beta\alpha}F_\gamma^\beta-\frac{1}{4}g_{\alpha\gamma}F_{\delta\beta}F^{\delta\beta}\right)} \tag{12.4.245}$$

This is the "electromagnetic stress-energy tensor".

But we should also check that this result is symmetric. Then if we do the calculations (boring elementary algebra but we can give the details on readers request):

$$T^{\mu\nu}=\begin{bmatrix}\frac{1}{2}\left(\varepsilon_0E^2+\frac{1}{\mu_0}B^2\right) & S_{\text{x}}/c & S_{\text{y}}/c & S_{\text{z}}/c\\ S_{\text{x}}/c & -\sigma_{xx} & -\sigma_{\text{xy}} & -\sigma_{\text{xz}}\\ S_{\text{y}}/c & -\sigma_{yx} & -\sigma_{\text{yy}} & -\sigma_{\text{yz}}\\ S_{\text{z}}/c & -\sigma_{zx} & -\sigma_{\text{zy}} & -\sigma_{\text{zz}}\end{bmatrix} \tag{12.4.246}$$

where for recall:

$$\vec{S}=\frac{1}{\mu_0}\vec{E}\times\vec{B}=\frac{1}{\mu}\begin{pmatrix}E_yB_z-E_zB_y\\E_zB_x-E_xB_z\\E_xB_y-E_yB_x\end{pmatrix} \tag{12.4.247}$$

and:

$$\sigma_{ij}=\varepsilon_0E_iE_j+\frac{1}{\mu_0}B_iB_j-\frac{1}{2}\left(\varepsilon_0E^2+\frac{1}{\mu_0}B^2\right)\delta_{ij} \tag{12.4.248}$$

is the "Maxwell stress tensor".

12.4.5 Einstein's Field Equations

It is now time to tackle one of the most beautiful, one of the most famous equations of our time and that shines the eyes of many young students and science passionate: Einstein's field equations. The one that explains why matter (energy) curves space!!! There are several ways to obtain these equations. The two most common ones are either:

1. To have an engineer approach: That is to say we proceed by comparison with a known limiting result which is the law of gravitation of Newton (it is the one that we have chosen)
2. To have a pure mathematical approach (very elegant but a little fallen from the sky with some circular reasoning): That is to say that we use the Lagrangian formalism and seek by trial and errors a Lagrangian density which allows us to fall back on something known.

Well this having been said, let us recall before starting some results that we have obtained so far. First, we have succeeded in proving brilliantly that every particle (assumed to be free but left to interpretation ... in a curved space ...) follows the equation of motion of geodesics:

$$\frac{\mathrm{d}^2x^\mu}{\mathrm{d}s^2}+\Gamma^\mu_{\alpha\beta}\frac{\mathrm{d}x^\alpha}{\mathrm{d}s}\frac{\mathrm{d}x^\beta}{\mathrm{d}s} \tag{12.4.249}$$

In the section of Tensor Calculus, we have proved (not without difficulty...) what we name the "Einstein's tensor" (which is a constant in a given Riemannian space) is given by:

$$G^{\mu\nu}=R^{\mu\nu}-\frac{1}{2}g^{\mu\nu}R \tag{12.4.250}$$

where $R^{\mu\nu}$ is for recall the Ricci tensor (see section Tensor Calculus page 2127).

Since the covariant derivative of the Einstein's tensor is zero (see section Tensor Calculus page 2141) and we have proved that the covariant derivative of stress-energy tensor is also, then it is tempting to put:

$$\nabla^\rho G_{\rho\sigma}=\kappa\nabla^\rho T_{\rho\sigma}=0 \tag{12.4.251}$$

where κ is a normalization constant (commonly named: "Einstein's gravitational coupling constant") and must satisfy the relation so that it is homogeneous at the level of the units. So it comes (we should better say: "we think we can write...") after simplification:

$$G_{\rho\sigma}=\kappa T_{\rho\sigma} \tag{12.4.252}$$

To find the expression of the constant, we will place ourselves in the Newtonian limit and request that the preceding relation reproduce the Newton-Poisson equation for the gravitational potential φ (see section Astronomy page 5266):

$$\nabla^2\varphi=4\pi G\rho \tag{12.4.253}$$

Remark

This relation shows that the gravitational potential is connected to the matter density linearly through its second derivatives. Albert Einstein thought, therefore, that the first member of the equations of the field in General Relativity, member supposed to describe the geometry of space-time, must therefore somehow include the second derivatives, not of the gravitational potential, but of the potentials of the metric. In fact, Albert Einstein tried to generalize the right-hand side of the Poisson equation: the desired quantity must include not only the density of matter but also the momentum (as soon as the body is moving, its energy increases and therefore its mass). To evaluate the gravitational effect of a body, it was therefore necessary to combine its mass at rest with its momentum. It was finally the stress-energy tensor of rank 2 which is the generalization of the quadrivector momentum of Special Relativity.

We have proved earlier above that in the Newtonian limit (weak field approximation):

$$h_{00}=-\frac{2}{c^2}\varphi \qquad (12.4.254)$$

and in our definition of stress-energy tensor, for a distribution of matter at rest (or in a coordinate frame according to...) only the following component is non-zero:

$$T_{00}=\rho c^2 \qquad (12.4.255)$$

It follows that the Poisson equation can be written (notice that this assumes that the density is calculated from a three dimensional sphere of volume $V=4/3\pi r^3$...):

$$\nabla^2 h_{00}=\Delta h_{00}=\frac{\mathrm{d}^2}{\mathrm{d}^2 r}\left(-\frac{2}{c^2}\frac{2GM}{r}\right)=-\frac{8GM}{c^2r^3}=-\frac{8\pi G\rho}{c^2}=-\frac{8\pi G}{c^2}\frac{T_{00}}{c^2}=-\frac{8\pi G}{c^4}T_{00} \qquad (12.4.256)$$

Now let us return to the relation:

$$G_{\rho\sigma}=\kappa T_{\rho\sigma} \qquad (12.4.257)$$

By contracting the two members of the preceding relation, it comes:

$$g^{\rho\sigma}G_{\rho\sigma}=\kappa g^{\rho\sigma}T_{\rho\sigma} \qquad (12.4.258)$$

that is to say more explicitly (see section Tensor Calculus page 2141):

$$g^{\rho\sigma}\left(R_{\rho\sigma}-\frac{1}{2}Rg_{\rho\sigma}\right)=\kappa g^{\rho\sigma}T_{\rho\sigma} \qquad (12.4.259)$$

But, the Ricci scalar (see section Tensor Calculus page 2128) is given by:

$$R=g^{\rho\sigma}R_{\rho\sigma} \qquad (12.4.260)$$

It comes therefore:

$$\left(R-\frac{1}{2}Rg^{\rho\sigma}g_{\rho\sigma}\right)=\kappa g^{\rho\sigma}T_{\rho\sigma} \qquad (12.4.261)$$

Now in the special case of the Minkowski metric (with the signature $(-,+,+,+)$) it is immediate that:

$$g^{\rho\sigma}g_{\rho\sigma}=\eta^{\rho\sigma}\eta_{\rho\sigma}=4 \tag{12.4.262}$$

Therefore (implicitly we continue with the Minkowski metric!):

$$R-2R=\kappa g^{\rho\sigma}T_{\rho\sigma} \tag{12.4.263}$$

Using this last relation, the equation:

$$R_{\rho\sigma}=\kappa T_{\rho\sigma}+\frac{1}{2}Rg_{\rho\sigma} \tag{12.4.264}$$

can finally be written:

$$R_{\rho\sigma}=\kappa T_{\rho\sigma}+\frac{1}{2}(-\kappa g^{\rho\sigma}T_{\rho\sigma})g_{\rho\sigma}=\kappa\left(T_{\rho\sigma}-\frac{1}{2}g^{\rho\sigma}T_{\rho\sigma}g_{\rho\sigma}\right) \tag{12.4.265}$$

Let us focus on the component $\rho=\sigma=0$ (not to be confused with the notation of shear stress and density!!!) such that the preceding relation is written:

$$\begin{aligned}R_{00}&=\kappa\left(T_{00}-\frac{1}{2}(g^{00}T_{00})g_{00}\right)=\kappa\left(T_{00}-\frac{1}{2}((-1)\cdot T_{00})(-1)\right)\\&=\kappa\left(T_{00}-\frac{1}{2}T_{00}\right)=\kappa\frac{1}{2}T_{00}\end{aligned} \tag{12.4.266}$$

Let us write explicitly this last relation by using the definition of the Ricci tensor (see section Tensor Calculus page 2127) that is for recall:

$$R_{\alpha\beta}=R^{\mu}_{\alpha\mu\beta} \tag{12.4.267}$$

Then it comes:

$$R_{00}=R^{\mu}_{0\mu0} \tag{12.4.268}$$

But, the Riemann-Christoffel tensor developed in this particular case is given for recall by (see section Tensor Calculus page 2122):

$$R^{\mu}_{0,\mu0}=R^{\mu}_{0\mu0}=\partial_{\mu}\Gamma^{\mu}_{00}-\partial_{0}\Gamma^{\mu}_{0\mu}+\Gamma^{\gamma}_{00}\Gamma^{\mu}_{\mu\gamma}-\Gamma^{\gamma}_{0\mu}\Gamma^{\mu}_{0r} \tag{12.4.269}$$

Remark

In the absence of a gravitational field and in Cartesian coordinates, it is logical that all the Christoffel symbols are null. Indeed, the Christoffel symbols translate nothing more than the forces of inertia. But when we have a field of gravitation, the trajectories followed are no longer straight lines, even in the Newtonian case, then the Christoffel symbols are non-zero.

In the approximation of the weak field slowly variable over time, the Christoffel symbols are of order $\mathcal{O}^1$ and their products are of order $\mathcal{O}^2$ and the temporal derivatives are negligible in front of the spatial derivatives. It therefore remains only the terms of order $\mathcal{O}^1$ such that:

$$R_{00}=R^{\mu}_{0\mu0}\cong\partial_{\mu}\Gamma^{\mu}_{00} \tag{12.4.270}$$

But, we have proved in the section of Tensor Calculus (see page 2109) that:

$$\Gamma_{kj}^{i}=\frac{1}{2}g^{il}\left(\partial_k g_{lj}+\partial_j g_{kl}-\partial_l g_{kj}\right) \tag{12.4.271}$$

Since then:

$$R_{00}\cong\partial_\mu\Gamma_{00}^{\mu}=\partial_\mu\left(\frac{1}{2}g^{\mu l}\left(\partial_0 g_{l0}+\partial_0 g_{0l}-\partial_l g_{00}\right)\right) \tag{12.4.272}$$

But in the weak field approximation, the variation of the metric with respect to time is negligible compared to the spatial variation (the approximation is somewhat pulled by the hair it must be said ...):

$$\begin{aligned}R_{00}&\cong\partial_\mu\Gamma_{00}^{\mu}=\partial_\mu\left(\frac{1}{2}g^{\mu l}(-\partial_l g_{00})\right)=-\frac{1}{2}\partial_\mu\left[(\eta^{\mu l}+h^{\mu l})\partial_l(\eta_{00}+h_{00})\right]\\&\cong-\frac{1}{2}\partial_\mu(\eta^{\mu l}\partial_l h_{00})=-\frac{1}{2}\eta^{\mu l}\partial_\mu\partial_l h_{00}-\frac{1}{2}(\partial_l h_{00})(\partial_\mu\eta^{\mu l})\cong-\frac{1}{2}\eta^{\mu l}\partial_\mu\partial_l h_{00}\\&=-\frac{1}{2}\nabla^2 h_{00}\end{aligned} \tag{12.4.273}$$

Therefore, equating the both relations:

$$R_{00}=\kappa\frac{1}{2}T_{00}\qquad\text{and}\qquad R_{00}=-\frac{1}{2}\nabla^2 h_{00} \tag{12.4.274}$$

becomes (after the simplification by 2):

$$\nabla^2 h_{00}=-\kappa T_{00} \tag{12.4.275}$$

and we immediately notice that we fall back on:

$$\nabla^2 h_{00}=-\frac{8\pi G}{c^4}T_{00} \tag{12.4.276}$$

if and only if:

$$\kappa=\frac{8\pi G}{c^4} \tag{12.4.277}$$

Constant which is sometimes named "Einstein's constant". It follows immediately that the Ricci scalar is positive and therefore that we are locally in a spherical curvature space.

The "Einstein's field equations" (EFE) is therefore in definitive form:

$$G_{\mu\nu}=\frac{8\pi G}{c^4}T_{\mu\nu} \tag{12.4.278}$$

or more conventionally:

$$\boxed{R_{\mu\nu}-\frac{1}{2}Rg_{\mu\nu}=\frac{8\pi G}{c^4}T_{\mu\nu}} \tag{12.4.279}$$

Or in explicit form:

$$\left(\frac{\mathrm{d}\Gamma^{\sigma}_{\mu\nu}}{\mathrm{d}x^{\sigma}}+\Gamma^{\lambda}_{\mu\nu}\Gamma^{\sigma}_{\lambda\sigma}-\frac{\mathrm{d}\Gamma^{\sigma}_{\mu\sigma}}{\mathrm{d}x^{\nu}}-\Gamma^{\lambda}_{\mu\sigma}\Gamma^{\sigma}_{\lambda\nu}\right)-\frac{1}{2}g^{\mu\nu}\left(\frac{\mathrm{d}\Gamma^{\sigma}_{\mu\nu}}{\mathrm{d}x^{\sigma}}+\Gamma^{\lambda}_{\mu\nu}\Gamma^{\sigma}_{\lambda\sigma}-\frac{\mathrm{d}\Gamma^{\sigma}_{\mu\sigma}}{\mathrm{d}x^{\nu}}-\Gamma^{\lambda}_{\mu\sigma}\Gamma^{\sigma}_{\lambda\nu}\right)g_{\mu\nu}$$
$$=\frac{8\pi G}{c^4}\begin{bmatrix}\rho\gamma^2c^2 & \rho\gamma^2cv^x & \rho\gamma^2cv^y & \rho\gamma^2cv^z\\ \rho\gamma^2cv^x & \rho\gamma^2v^xv^x & \rho\gamma^2v^xv^y & \rho\gamma^2v^xv^z\\ \rho\gamma^2cv^y & \rho\gamma^2v^yv^x & \rho\gamma^2v^yv^y & \rho\gamma^2v^yv^z\\ \rho\gamma^2cv^z & \rho\gamma^2v^zv^x & \rho\gamma^2v^zv^y & \rho\gamma^2v^zv^z\end{bmatrix} \tag{12.4.280}$$

The left-hand part represents the curvature of space-time as determined by the metric and the right-hand expression represents a modelization of the space-time content of mass / energy. This equation can then be interpreted as a set of equations describing how the curvature of space-time is related to the mass-energy content of the Universe. These equations, as well as the geodesic equation, form the core of the mathematical formulation of General Relativity.

The EFE is therefore a dynamic equation describing how matter and energy modify the geometry of space-time. This curvature of the geometry around a source of matter is then interpreted as the gravitational field of this source. The movement of objects in this field is described very precisely by the equation of its geodesic.

Similar to the way that electromagnetic fields are determined using charges and currents via Maxwell's equations, the EFE are used to determine the space-time geometry resulting from the presence of mass–energy and linear momentum, that is, they determine the metric tensor of space-time for a given arrangement of stress–energy in the space-time.

The mainstream metrics that we will study in this textbook will be (the first one is already knows to us): the Minkowski metric for flat static space, the Schwarschild metric for curved static space, the Friedmann-Lemaître-Robertson-Walker to describe the Universe metric, the Kerr metric for dynamic curve space and the Morris-Thorne metric for worm-holes:

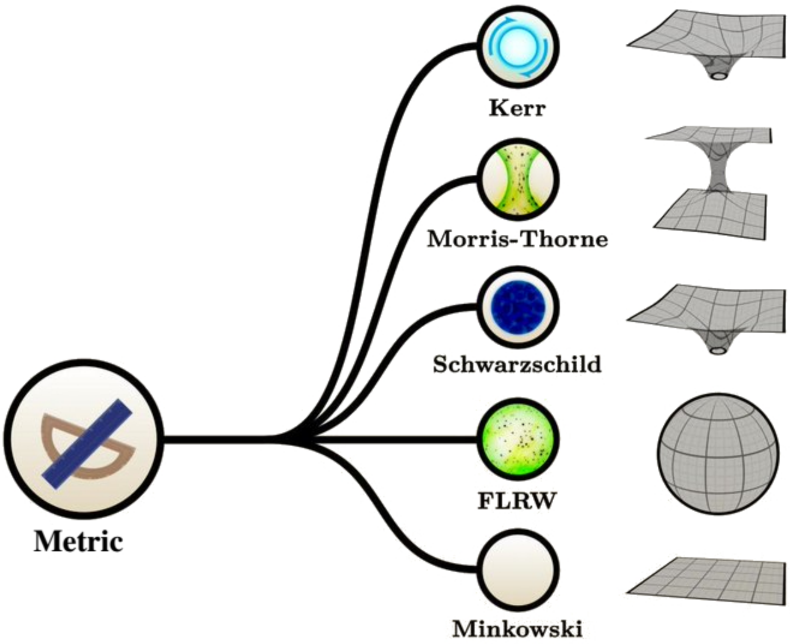


Figure 12.219: Some mainstream metrics used in General Relativity

Remark

Keep in mind that the perceived "force" of gravity is a manifestation of space-time curvature, not gravity itself! Gravity is what causes space-time to curve due to energy/mass, and the hypothesized gravitons could be the mechanism for this. In some Quantum Gravitation theories gravity is still a force, it's just the force that causes space-time curvature and not what causes gravitational attraction (not directly anyway)!

On the other hand, we have just seen that Einstein's equation reduces to the laws of Newton's gravity by using the approximation of weak fields and slow movements.

These differential equations are in general a nightmare to solve, the Ricci scalars and tensors are contractions of the Riemann tensor, which include the derivatives and products of the Christoffel symbols, which are themselves constructed on the inverse metric tensor and on the derivatives of it. To compute the whole, it is possible to construct energy-momentum tensors that can invoke the metric as well. It is therefore very difficult to solve the Albert Einstein equations of fields in the general case. Exact solutions for the EFE can only be found under simplifying assumptions such as symmetry. Special classes of exact solutions are most often studied as they model many gravitational phenomena, such as rotating Black Holes and the expanding universe. Further simplification is achieved in approximating the actual space-time as flat space-time with a small deviation, leading to the linearised EFE. These equations are used to study phenomena such as gravitational waves.

Since the stress-energy tensor has $4\cdot 4=16$ components, 10 of which are actually unique (independent) since the tensor is symmetric (triangle + diagonal), we can see the Einstein equation of the fields as 10 second-order differential equations coupled on field tensor metric g_{ij}.

Some people are confused about how the curvature of space-time and gravity are related. I am going to explain mainly that starting with simpler examples, and moving to more complicated ones.

Okay, let's say we have a sheet of rubber. This is the classic example of space-time. Let's say we take a bowling ball, and set it on the taut sheet of rubber. It has a large mass (compared to what else we'll be putting on the sheet), therefore the sheet curves a lot for the bowling ball. We now have an image in our head like the one below:

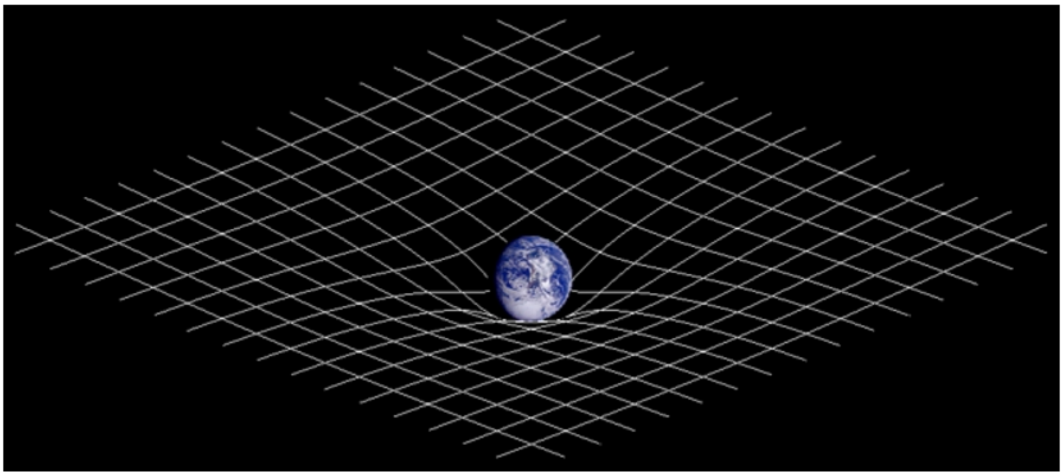

Figure 12.220: **2D naive representation of space curve near Earth**

So mass leads to curvature. Then, let us take a baseball, say, and set it near the bowling ball. It rolls toward the bowling ball, right? This occurs because of the curvature of the sheet. So, then, curvature leads to gravity. So, if an object has large mass, it will curve space-time dramatically, leading to strong gravity.

This is, of course, an overly simplistic example. It is 2D, and it doesn't take into account other factors. Let us move to 3D (keeping in mind the Universe is accepted to be at 4D, ignoring the holographic principle). The mass of a bowling ball now sucks in space around it, sort of like in the picture below:

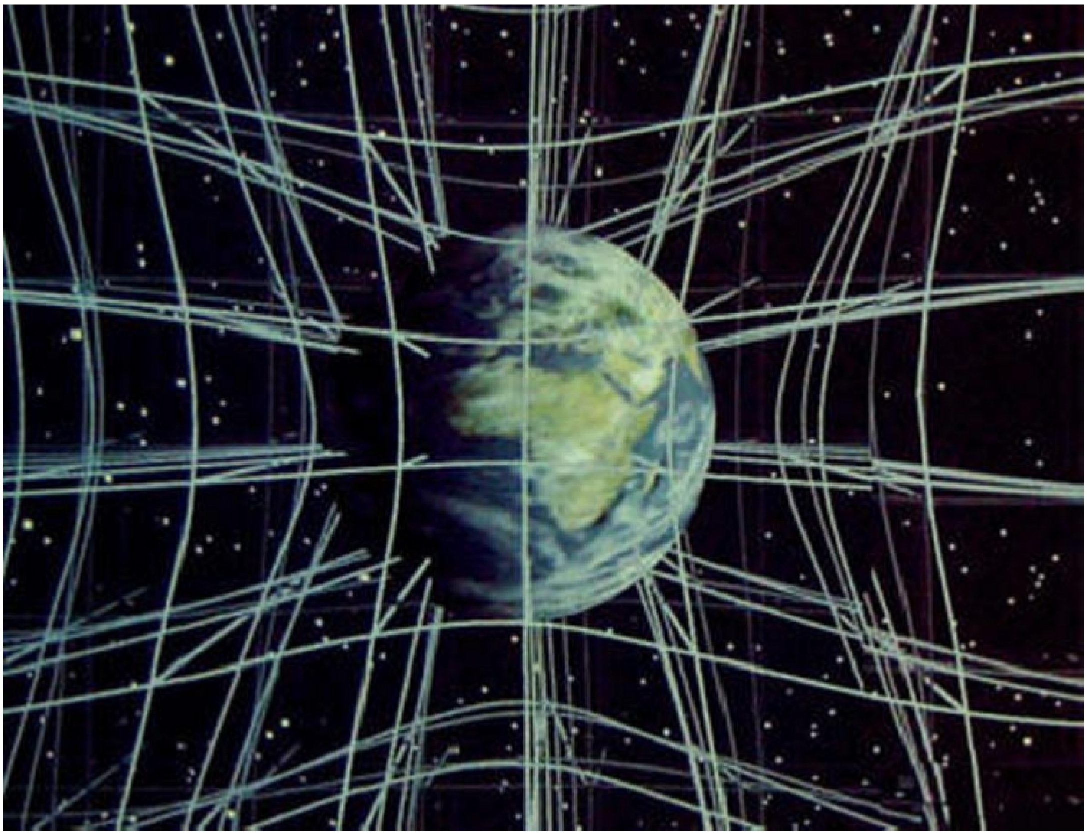

Figure 12.221: 3D naive representation of curved space near Earth

And now, in this case, we can see (or understand) that more mass still leads to more curvature. The greater the mass, the more space-time will "contract" around the object. So we still think that mass leads to curvature. Now, if we set an object near this massive object (like the Moon next to Earth) it is "sucked in" sort of, by the curvature of space-time, though of course the Moon contracts space-time around it as well. At this point, we can reasonably still conclude that in 3D, mass leads to curvature which leads to gravity.

A quick glance at the constant of proportionality in the Einstein's field equations gives one a rough feeling of much stress-energy is needed to curve space. In SI units, the gravitational constant G is about $6.67\cdot 10^{-11}\,[\text{m}^3\cdot\text{kg}^{-1}\cdot\text{s}^{-2}]$ while the speed for light c is approximately $3.00\cdot 10^{8}\,[\text{m}\cdot\text{s}^{-1}]$. The Einstein's field equations is then in explicit numerical value given by:

$$\boxed{G_{\mu\nu}=\frac{8\pi G}{c^4}T_{\mu\nu}\cong 2.08\cdot 10^{-43}T_{\mu\nu}} \qquad (12.4.281)$$

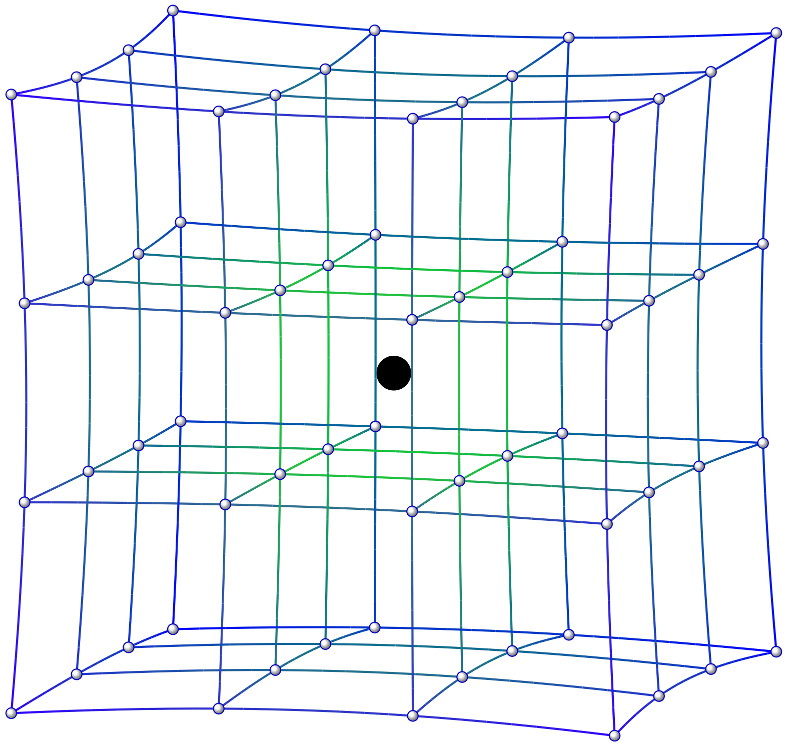

Figure 12.222: **3D naive representation of space curve with TikZ**

The Sun (actually a G2V-type star, aka yellow dwarf) has an average mass-energy density (the dominant component of the stress-energy tensor) of $T^{00} \cong 1.27 \cdot 10^{20}\,[\mathrm{kg} \cdot \mathrm{m}^{-1} \cdot \mathrm{s}^{-2}]$. The corresponding component of the Einstein Tensor is therefore $G_{00} \cong 2.64 \cdot 10^{-23}\,[\mathrm{m}^{-2}]$. By comparison the Einstein tensor for the flat Minkowski metric is identically zero. So to see a curvature we need to look at hyper-energetic phenomena, like a collapsing star, to find an Einstein tensor component appreciable greater than this. Even though the space-time metric $g_{\mu\nu}$ is not generally flat, throughout most of the universe it is flat enough to be considered as small perturbation of a flat background metric:

$$g_{\mu\nu} = \eta_{\mu\nu} + h_{\mu\nu} \qquad (12.4.282)$$

But, as I said earlier, the Universe is generally thought of as 4D. What does our picture look like when we add time? Well, the time dimension is contracted around a massive object. So let us picture our previous example but that the fabric of space-time has a few clocks embedded in it occasionally. As the space stretches and contracts, so will the clocks (the "time") and so the time on those clocks will be "wrong" - it'll differ from the other clocks. And in this case, as the Earth contracts space and time around it, it changes the time and space (it curves space-time) and so when another object enters our region of space-time, it is "sucked in" still, but so is it's time. This is, of course, a very extreme example, but I hope this shows that we can conclude that mass leads to curvature which leads to gravity.

12.4.5.1 Cosmological Constant (CC)

Albert Einstein modified his original field equations to include a cosmological constant term Λ proportional to the metric that led afterwards the Universe model to be static (see section Cosmogony page 6012).

To see how this constant was introduced let us recall that we have proved so far that:

$$\nabla^\rho G_{\rho\sigma}=\frac{8\pi G}{c^4}\nabla^\rho T_{\rho\sigma} \tag{12.4.283}$$

or more explicitly:

$$\nabla^\rho\left(R_{\rho\sigma}-\frac{1}{2}g_{\rho\sigma}R\right)=\frac{8\pi G}{c^4}\nabla^\rho T_{\rho\sigma} \tag{12.4.284}$$

That is to say:

$$\nabla^\rho R_{\rho\sigma}-\frac{1}{2}\nabla^\rho g_{\rho\sigma}R=\frac{8\pi G}{c^4}\nabla^\rho T_{\rho\sigma} \tag{12.4.285}$$

But we have proved in the section of Tensor Calculus that the covariant derivative kills the metric (see page 2117), that is to say for recall:

$$\nabla^\rho g_{\rho\sigma}=0 \tag{12.4.286}$$

Therefore if we choose a constant Λ the latter relation can also we written:

$$\Lambda\nabla^\rho g_{\rho\sigma}=\Lambda\cdot 0 \tag{12.4.287}$$

Obviously:

$$\nabla^\rho\left(\Lambda g_{\rho\sigma}\right)=0 \tag{12.4.288}$$

So nothing prevents us to put this covariant derivative in:

$$\nabla^\rho R_{\rho\sigma}-\frac{1}{2}\nabla^\rho g_{\rho\sigma}R=\frac{8\pi G}{c^4}\nabla^\rho T_{\rho\sigma} \tag{12.4.289}$$

as we can write:

$$\nabla^\rho R_{\rho\sigma}-\frac{1}{2}\nabla^\rho g_{\rho\sigma}R+0=\frac{8\pi G}{c^4}\nabla^\rho T_{\rho\sigma} \tag{12.4.290}$$

and replacing the 0 by the covariant derivative of the metric:

$$\nabla^\rho R_{\rho\sigma}-\frac{1}{2}\nabla^\rho g_{\rho\sigma}R+\nabla^\rho\left(\Lambda g_{\rho\sigma}\right)=\frac{8\pi G}{c^4}\nabla^\rho T_{\rho\sigma} \tag{12.4.291}$$

After factorization we get:

$$\nabla^\rho\left(R_{\rho\sigma}-\frac{1}{2}g_{\rho\sigma}R+\Lambda g_{\rho\sigma}\right)=\frac{8\pi G}{c^4}\nabla^\rho T_{\rho\sigma} \tag{12.4.292}$$

And simplifying we get the "general Einstein's field equations":

$$\boxed{\underbrace{R_{\rho\sigma}-\frac{1}{2}g_{\rho\sigma}R+\Lambda g_{\rho\sigma}}_{\text{pure geometry}}=\underbrace{\frac{8\pi G}{c^4}T_{\rho\sigma}}_{\text{properties of matter}}} \tag{12.4.293}$$

where Λ is the so named "cosmological constant" (a.k.a. "dark energy" in contemporary physics). It is also many times written as following:

$$G_{\mu\nu}+\Lambda g_{\mu\nu}=\kappa T_{\mu\nu} \tag{12.4.294}$$

Remember that in the equation above we have the stress-energy tensor $T_{\rho\sigma}$ that is in $[\mathrm{J}\cdot\mathrm{m}^{-3}]$, the metric $g_{\rho\sigma}$ that is dimensionless $[-]$ and the Ricci tensor $R_{\rho\sigma}$ but also the cosmological constant Λ and the Ricci scalar R that are all three in $[\mathrm{m}^{-1}]$. And remember that G has for units $[\mathrm{kg}^{-1}\cdot\mathrm{m}^3\cdot\mathrm{s}^{-2}]$ (hence $8\pi Gc^{-4}$ is in $[\mathrm{J}\cdot\mathrm{m}^{-1}]$.

Caution!!! Side note, with $T_{\mu\nu}=0$ and $\Lambda=0$, you get $R_{\mu\nu}=\frac{1}{2}Rg_{\mu\nu}$, which only equals zero if and only if $R=R_{\mu}^{\mu}=0$. The fact that the energy-momentum tensor is named the "source of curvature" doesn't mean that there can't be any curvature where there is no energy-momentum. In fact, even if $T_{\mu\nu}=0$ across all space-time, there are still non-trivial solutions of Einstein's equations, in the form of gravitational waves. It is automatic that any Ricci-flat manifold has zero scalar curvature; the best-known spaces in this class are the Calabi-Yau manifolds. There are also metrics with zero scalar curvature but non-vanishing Ricci curvature!

The equations are symmetric; that is, $\mu\nu=\nu\mu$. So the ten equations we have mentioned earlier above are:

1. $G_{00}+\Lambda g_{00}=\kappa T_{00}$
2. $G_{01}+\Lambda g_{01}=\kappa T_{01}$
3. $G_{02}+\Lambda g_{02}=\kappa T_{02}$
4. $G_{03}+\Lambda g_{03}=\kappa T_{03}$
5. $G_{11}+\Lambda g_{11}=\kappa T_{11}$
6. $G_{12}+\Lambda g_{12}=\kappa T_{12}$
7. $G_{13}+\Lambda g_{13}=\kappa T_{13}$
8. $G_{22}+\Lambda g_{22}=\kappa T_{22}$
9. $G_{23}+\Lambda g_{23}=\kappa T_{23}$
10. $G_{33}+\Lambda g_{33}=\kappa T_{33}$

The cosmological constant may be thought as the energy density associated with vacuum, the space absolutely void of particles. This could be a kind of "ground level energy", which often appears in quantum physics. In fact, some theories of elementary particles predict cosmological constant but, unfortunately, of much higher value compared to the actual observations (but the actual observation may be not accurate!). Given this association, the term "dark energy" is often used to describe the origin of the cosmological constant.

Remark

So General Relativity doesn't tell us anything about the value of the cosmological constant. In quantum field theory, however, we can calculate the vacuum energy density and it comes out to be infinitely large. But in the absence of gravity this doesn't matter: we never measure absolute energies anyway, we merely measure energy differences.

The latter relation can be found also in many textbooks in natural units (see section Principia page 3124) and rearranged a little bit as following:

$$R_{\rho\sigma}-\frac{1}{2}g_{\rho\sigma}R=8\pi T_{\rho\sigma}-\Lambda g_{\rho\sigma} \tag{12.4.295}$$

The effort from Albert Einstein to introduce this constant was unsuccessful because:

- The universe described by this theory was unstable
- Observations by Edwin Hubble confirmed that our Universe is expanding

So, Albert Einstein abandoned Λ, calling it the "biggest blunder [he] ever made".

Despite Albert Einstein's motivation for introducing the cosmological constant term, there is nothing inconsistent with the presence of such a term in the equations. For many years the cosmological constant was almost universally considered to be 0. However, recent improved astronomical techniques have found that a positive value of Λ is needed to explain observations that seems to give an accelerating universe.

Let us now rearrange the Einstein Field Equations with the cosmological constant by rearranging it a bit:

$$R_{\rho\sigma}-\frac{1}{2}g_{\rho\sigma}R+=\frac{8\pi G}{c^4}\left(T_{\rho\sigma}-\frac{\Lambda c^4}{8\pi G}g_{\rho\sigma}\right) \tag{12.4.296}$$

Hence the expression of the stress-impulsion tensor for vacuum (i.e. the energy density for recall!):

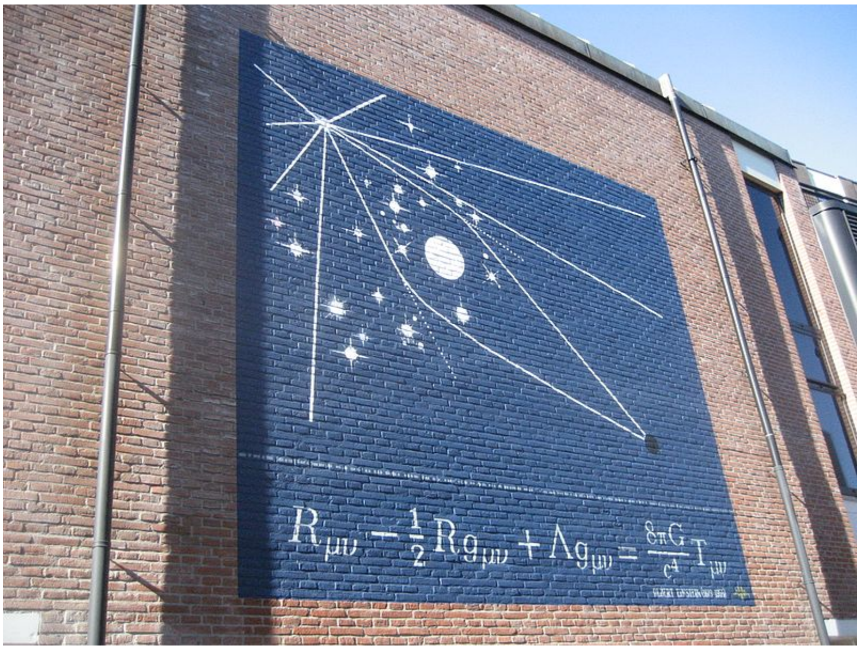
$$T_{\rho\sigma}^{\text{vacuum}}=\frac{\Lambda c^4}{8\pi G}g_{\rho\sigma} \tag{12.4.297}$$

If we compare this expression with that of a perfect fluid obtained earlier above:

$$T^{ij}\cong\left(\rho+\frac{P}{c^2}\right)u^iu^j-Pg^{ij} \tag{12.4.298}$$

We may assimilate vacuum to the pressure term, hence as a fluid of pressure:

$$P=-\frac{\Lambda c^4}{8\pi G}g_{\rho\sigma} \tag{12.4.299}$$



$R_{\mu\nu} - \frac{1}{2}Rg_{\mu\nu} + \Lambda g_{\mu\nu} = \frac{8\pi G}{c^4}T_{\mu\nu}$

Figure 12.223: **Diagram of gravitational lensing with formula of Albert Einstein on a wall of Museum Boerhaave, Leiden in Netherlands (source: Wikipedia, author: Stichting Tegenbeeld, photograph: Vysotsky)**

We can also trace invert the Einstein Field Equations (in some cases it helps to solve problems in an easier way!). We start from the EFE:

$$R_{\mu\nu}-\frac{1}{2}Rg_{\mu\nu}+\Lambda g_{\mu\nu}=\frac{8\pi G}{c^4}T_{\mu\nu} \quad (12.4.300)$$

and let us recall that:

$$g_{\mu\nu}g^{\mu\nu}=\delta_{\nu}^{\nu}=4 \quad (12.4.301)$$

So multiplying the EFE both sides by $g^{\mu\nu}$ leads us to:

$$R-\frac{1}{2}R\cdot 4+\Lambda\cdot 4=\frac{8\pi G}{c^4}T \quad (12.4.302)$$

Multiplying both sides by $-\frac{1}{2}g_{\mu\nu}$ we get:

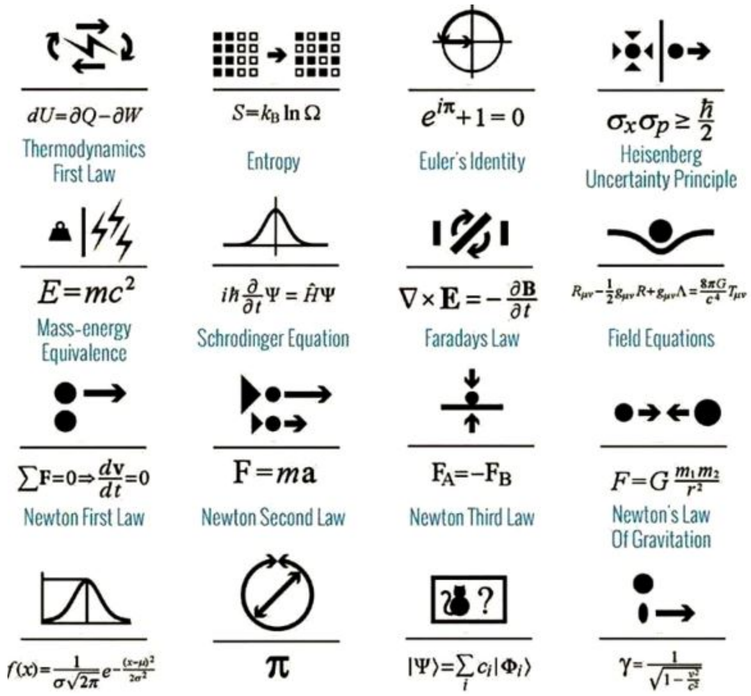
$$-\frac{1}{2}g_{\mu\nu}R=\frac{1}{2}g_{\mu\nu}\frac{8\pi G}{c^4}T-2g_{\mu\nu}\Lambda \quad (12.4.303)$$

where $T=T_{\mu\nu}g^{\mu\nu}$.

Subtracting the EFE gives us finally:

$$\boxed{R_{\mu\nu}=\frac{8\pi G}{c^4}\left(T_{\mu\nu}-\frac{1}{2}Tg_{\mu\nu}\right)+g_{\mu\nu}\Lambda} \quad (12.4.304)$$

If you had the courage (...) to read all the book so far in details, then now you can really understand the famous Internet illustration below as you have seen all the proofs of the relations visible on it:



$dU=\partial Q-\partial W$
Thermodynamics First Law
$S=k_B \ln \Omega$
Entropy
$e^{i\pi}+1=0$
Euler's Identity
$\sigma_x\sigma_p \geq \frac{\hbar}{2}$
Heisenberg Uncertainty Principle
$E=mc^2$
Mass-energy Equivalence
$i\hbar\frac{\partial}{\partial t}\Psi=\hat{H}\Psi$
Schrodinger Equation
$\nabla\times\mathbf{E}=-\frac{\partial\mathbf{B}}{\partial t}$
Faradays Law
$R_{\mu\nu}-\frac{1}{2}g_{\mu\nu}R+g_{\mu\nu}\Lambda=\frac{8\pi G}{c^4}T_{\mu\nu}$
Field Equations
$\sum\mathbf{F}=0 \Rightarrow \frac{d\mathbf{v}}{dt}=0$
Newton First Law
$\mathbf{F}=m\mathbf{a}$
Newton Second Law
$\mathrm{F_A}=-\mathrm{F_B}$
Newton Third Law
$F=G\frac{m_1m_2}{r^2}$
Newton's Law Of Gravitation
$f(x)=\frac{1}{\sigma\sqrt{2\pi}}e^{-\frac{(x-\mu)^2}{2\sigma^2}}$
π
$|\Psi\rangle=\sum_i c_i|\Phi_i\rangle$
?
$\gamma=\frac{1}{\sqrt{1-\frac{v^2}{c^2}}}$

Caution!!! There is no principle of physics yet, at least in this beginning of the 121st century (holocene calendar), that says physicals laws or constants have to be the same everywhere and always. Indeed, the reader must remember that the "laws" of physics are **descriptive**, not **imperative** and therefore they are some observed regularity in what we can observe experimentally with sufficiently wide occurrence or relevance! Asking whether the laws can change is no more and no less than asking whether regularities which have been observed up till now might not be quite as universal as was thought. The answer to that is: YES! This could drive the reader a bit mad. Indeed, how can we possibly do Science if the rules keep changing? But if you are a professional active scientist, you have to face up to that possibility - and you have a responsibility to check out if there is evidence beyond reasonable doubt about it! We will repeat this warning multiple times in this textbook as its seems that this is something necessary!

12.4.5.2 Weak field approximation with cosmological constant

As we have promised earlier above, we will see now how to fall back on the Newton-Poisson equation directly from the general Einstein's field equations. Obviously that means we just do the inverse reasoning that gave us the opportunity the build the classical Einstein's field equations!!! But they will however be a small difference... we will include the cosmological constant and see how it change the Newton-Poisson equation.

For this, we start obviously from:

$$R_{\rho\sigma}-\frac{1}{2}g_{\rho\sigma}R+\Lambda g_{\rho\sigma}=\frac{8\pi G}{c^4}T_{\rho\sigma} \tag{12.4.305}$$

Let us write these equations in the equivalent form:

$$R_{\rho\sigma}=\frac{8\pi G}{c^4}\left(T_{\rho\sigma}+\frac{1}{2}g_{\rho\sigma}R\right)-\Lambda g_{\rho\sigma} \tag{12.4.306}$$

In weak field and low speed we know that $T_{00}=\rho c^2$. But we will also assume that $R=T=\rho c^2$, so that we can write[47]:

$$R_{00}=\frac{8\pi G}{c^4}\left(\rho c^2+\frac{1}{2}g_{00}\rho c^2\right)-\Lambda g_{00} \tag{12.4.307}$$

But as we proved earlier during our introduction of the Newtonian approximation, we have:

$$R_{00}\cong-\frac{1}{2}\nabla^2 h_{00} \tag{12.4.308}$$

Therefore:

$$-\frac{1}{2}\nabla^2 h_{00}=\frac{8\pi G}{c^4}\left(\rho c^2+\frac{1}{2}(\eta_{00}+h_{00})\rho c^2\right)-\Lambda(\eta_{00}+h_{00}) \tag{12.4.309}$$

Hence (still using the $-,+,+,+$ metric signature):

$$-\frac{1}{2}\nabla^2 h_{00}=\frac{8\pi G}{c^4}\rho c^2\left(1+\frac{1}{2}(-1+h_{00})\right)-\Lambda(-1+h_{00}) \tag{12.4.310}$$

With the traditional Newtonian approximation:

$$h_{00}=-\frac{2}{c^2}\varphi \tag{12.4.311}$$

It gives :

$$\frac{1}{c^2}\nabla^2\varphi=\frac{8\pi G}{c^4}\rho c^2\left(1+\frac{1}{2}\left(-1-\frac{2}{c^2}\varphi\right)\right)-\Lambda\left(-1-\frac{2}{c^2}\varphi\right) \tag{12.4.312}$$

Multiplying both sides by c^2 we get after simplification:

$$\nabla^2\varphi=8\pi G\rho\left(\frac{1}{2}\left(1+\frac{2}{c^2}\varphi\right)\right)+\Lambda c^2\left(1+\frac{2}{c^2}\varphi\right) \tag{12.4.313}$$

Hence:

$$\nabla^2\varphi=4\pi G\rho\left(1+\frac{2}{c^2}\varphi\right)+\Lambda c^2\left(1+\frac{2}{c^2}\varphi\right) \tag{12.4.314}$$

in the approximation:

$$\left|\frac{2}{c^2}\varphi\right|\ll 1 \tag{12.4.315}$$

it gives the following Newtonian approximation:

$$\boxed{\nabla^2\varphi=4\pi G\rho+\Lambda c^2} \tag{12.4.316}$$

As $\Lambda\cdot c^2$, as we will see further below, is also very very small we shall also put it as equal to zero.

---

[47] In the weak field approximation the Ricci scalar should be equal to zero... but we do physics and not maths...

Remark

An inverse calculation then gives the following potential:

$$\varphi = \frac{-GM}{r} + \frac{\Lambda c^2 r^2}{2} \tag{12.4.317}$$

Obviously the conclusion depends on the fact if experimental data gives $\Lambda = 0$, $\Lambda < 0$ or $\Lambda > 0$! What we still don't really know with enough accuracy still in this early 121st century (holocene calendar) as its values is very near zero (order of 10^{-52})!

The interesting thing is that at the Galaxy scale (i.e. with galactical input numerical values), that latter results shows that if $\Lambda > 0$, the potential becomes positive and hence repulse objects (the Universe seems then to expand faster), and when $\Lambda > 0$ the gravitation becomes very strong again at very far distances from the source! Anyway so far, experimental observation seem to reject that. That's why we are authorized to keep Λ in the final expression.

If the reader is asking himself: how can we derive the Lorentz transformation from General Relativity? This is really asking: how is the Minkowski metric a solution of the vacuum Einstein equation? Because Special Relativity is just the geometry defined by the Minkowski metric.

If we take the Einstein equation and turn off gravity we get the vacuum Einstein equation $G_{ab} = 0$. The Minkowski metric is a solution of this equation, but of course there are lots of others. From this question we may be hoping that the Einstein equation will simplify in the absence of gravity, and this will make it obvious how Special Relativity emerges. Sadly this isn't the case, because even in the absence of mass gravity waves are still allowed!

We don't think there is any way to simplify the Einstein equation to make the Minkowski metric the only solution. We can require that the first derivatives of the metric vanish, but this is really getting the flat space solution by requiring that space not be curved, which is a bit of a tautology. The problem is that in Special Relativity the Minkowski metric is an assumption i.e. it's where you start from. In General Relativity the Minkowski metric is just one among many solutions so there's nothing fundamental about it.

12.4.5.3 Einstein-Maxwell equations

If the energy-momentum tensor $T^{\alpha\beta}$ is that of an electromagnetic field in free space, i.e. if the electromagnetic stress–energy tensor (see page 5764):

$$T^{\alpha\beta} = -\frac{1}{\mu_0}\left(F^{\alpha\psi}F_{\psi}{}^{\beta} - \frac{1}{4}g^{\alpha\beta}F_{\psi\tau}F^{\psi\tau}\right) \tag{12.4.318}$$

is used, then the Einstein field equations are named the "Einstein–Maxwell equations" (with cosmological constant Λ, taken to be zero in conventional relativity theory):

$$R^{\alpha\beta} - \frac{1}{2}Rg^{\alpha\beta} + \Lambda g^{\alpha\beta} = -\frac{8\pi G}{c^4\mu_0}\left(F^{\alpha\psi}F_{\psi}{}^{\beta} - \frac{1}{4}g^{\alpha\beta}F_{\psi\tau}F^{\psi\tau}\right) \tag{12.4.319}$$

or written more commonly:

$$\boxed{R^{\alpha\beta} - \frac{1}{2}Rg^{\alpha\beta} + \Lambda g^{\alpha\beta} = \frac{8\pi G}{c^4\mu_0}\left(F^{\alpha\psi}F_{\psi}{}^{\beta} + \frac{1}{4}g^{\alpha\beta}F_{\psi\tau}F^{\psi\tau}\right)} \tag{12.4.320}$$

12.4.5.4 Schwarzschild Solution

The "Schwarzschild metric" is an approximate solution of the EFE in the case of an isotropic non-rotating gravitational field, without electric charge, zero universal cosmological constant and at a great distance from the source. It provides the three main proofs of General Relativity: the shift of clocks, the deviation of light by a dense celestial body and the advance of the perihelion of Mercury. These three proofs are very important because Einstein's equation was not experimentally demonstrated at the time. The solution is a useful approximation for describing slowly rotating astronomical objects such as many stars and planets, including Earth and the Sun. The solution is named after Karl Schwarzschild, who first published the solution in 11916 (holocene calendar).

To introduce this metric, let us imagine a source (for example the Sun) which produces a gravitational field by means of its mass M. We seek, in order to compare with the experiment, the solutions of Einstein's equation (in other words: the metric) outside the source (of the Sun therefore ...) of mass M.

Remark

There are several mathematical techniques to introduce the Schwarzschild metric. The reader will be able to search, for example, in the literature or on the Internet the one using a gauge transformation ("Einstein gauge" with the "harmonic gauge") for the local perturbation constraint. This method is very elegant but very math oriented and we prefer as the reader already know it the "engineer" method...

In other words, this is like assuming to have in the region of space that interests us (considering that there is only the star in question and nothing else around, not even the energy / mass specific to the gravitational field) the following property:

$$T_{\mu\nu}=0 \tag{12.4.321}$$

So the EFE proved just above without cosmological constant:

$$R_{\mu\nu}-\frac{1}{2}Rg_{\mu\nu}=\frac{8\pi G}{c^4}T_{\mu\nu} \tag{12.4.322}$$

then becomes:

$$R_{\mu\nu}-\frac{1}{2}Rg_{\mu\nu}=0 \tag{12.4.323}$$

But we proved above that this last relation can also be written using the definition of the Ricci scalar that is given for recall by:

$$R=g^{\mu\nu}R_{\mu\nu} \tag{12.4.324}$$

as following:

$$R_{\mu\nu}-\frac{1}{2}R_{\mu\nu}g^{\mu\nu}g_{\mu\nu}=R_{\mu\nu}\left(1-\frac{1}{2}g^{\mu\nu}g_{\mu\nu}\right)=0 \tag{12.4.325}$$

and since the parenthesis is not null since we have proved above that in the Minkowski metric:

$$g^{\rho\sigma}g_{\rho\sigma}=4 \tag{12.4.326}$$

it remains:

$$\boxed{R_{\mu\nu}=0} \tag{12.4.327}$$

and therefore in extenso the scalar of Ricci is also null. This last relation is named the "vacuum field equations".

$R_{\mu\nu}=0$
$\delta\int ds=0$
ALBERT
EINSTEIN

Figure 12.224: **Swiss commemorative coin showing the vacuum field equations with zero cosmological constant (top) and action minimization**

We must therefore find the metric that satisfies this relation (in other words, a metric that far from the source corresponds to a flat space since the Ricci tensor is zero). As there are several possibilities let us focus on a particularly elegant case with as the physicists like it ... full of symmetries.

The idea is therefore to find a metric, if possible independent of time (therefore the gravitational field as well will be independent of time!) and ... with spherical symmetry (a star or planet being itself of this form), taking into account the mass of the star (this is the major objective!) and such that far enough from the source (...) or when the mass is zero we fall back on the classical metric known and see earlier above:

$$\mathrm{d}s^2=\mathrm{d}r^2+r^2\mathrm{d}\theta^2+r^2\sin^2(\theta)\mathrm{d}\phi^2 \tag{12.4.328}$$

But this is not totally accurate! Indeed, we work in space-time. But, we have seen that the equation of the curvilinear metric is given in a flat space-time by:

$$\mathrm{d}s^2=c^2\mathrm{d}t^2-(\mathrm{d}x^2+\mathrm{d}y^2+\mathrm{d}z^2) \tag{12.4.329}$$

by passing in spherical coordinates we then have:

$$\mathrm{d}s^2=c^2\mathrm{d}t^2-(\mathrm{d}r^2+r^2\mathrm{d}\theta^2+r^2\sin^2(\theta)\mathrm{d}\phi) \tag{12.4.330}$$

And it is on this equation of the metric that we must fall back when we are far from the source or that the mass is extremely small ($M=0$). That is to say the Schwarzschild metric must therefore be asymptotically flat, that is to say corresponding to the flat space of Minkowski.

So let's get to the task. First, we start from what we know (it's better if we can...!). Which means:

$$\mathrm{d}s^2=g_{\mu\nu}\mathrm{d}x^\mu\mathrm{d}x^\nu \tag{12.4.331}$$

And in spherical coordinates including time we have the components r, θ, ϕ, t. Rigorously, we denote by:

$$(x^{\alpha}) = (ct, r, \theta, \phi) \tag{12.4.332}$$

the "Schwarzschild coordinates".

On a total of 16 terms implied by the prior-previous relation, we finally retain 10 namely: the 4 terms of the diagonal and the 6 other terms of interaction so as to obtain:

$$\mathrm{d}s^2 = A\mathrm{d}t^2 - \begin{pmatrix} B\mathrm{d}r^2 + C\mathrm{d}\theta^2 + D\mathrm{d}\phi^2 \\ +F\mathrm{d}r\mathrm{d}\theta + G\mathrm{d}r\mathrm{d}\phi + H\mathrm{d}r\mathrm{d}t + I\mathrm{d}\theta\mathrm{d}\phi + J\mathrm{d}\theta\mathrm{d}t + K\mathrm{d}\phi\mathrm{d}t \end{pmatrix} \tag{12.4.333}$$

where A, B, C, ... are coefficients to be determined.

Before tackling this work, we know that according to one of our starting constraints, when the mass is weak or we are far from a non high-speed rotating source, we must therefore fall back on:

$$\mathrm{d}s^2 = c^2\mathrm{d}t^2 - \left(\mathrm{d}r^2 + r^2\mathrm{d}\theta^2 + r^2\sin^2(\theta)\mathrm{d}\phi^2\right) \tag{12.4.334}$$

therefore intuitively we can already write:

$$\mathrm{d}s^2 = A\mathrm{d}t^2 - \begin{pmatrix} B\mathrm{d}r^2 + Cr^2\mathrm{d}\theta^2 + Dr^2\sin^2(\theta)\mathrm{d}\phi^2 \\ +F\mathrm{d}r\mathrm{d}\theta + G\mathrm{d}r\mathrm{d}\phi + H\mathrm{d}r\mathrm{d}t + I\mathrm{d}\theta\mathrm{d}\phi + J\mathrm{d}\theta\mathrm{d}t + K\mathrm{d}\phi\mathrm{d}t \end{pmatrix} \tag{12.4.335}$$

what we must admit it ... is a clear progress ...!

If as we have imposed it to ourselves at the beginning, the equation of the metric is independent of time, we can by symmetry of time (hypothesis ...) make the following change of variable:

$$\mathrm{d}t = -\mathrm{d}t \tag{12.4.336}$$

without this changing anything in our $\mathrm{d}s^2$. But, we realize very quick that this will not be the case. Immediately, for this to be satisfied we see that we must have:

$$H = J = K = 0 \tag{12.4.337}$$

Which brings us (it's already better!) to:

$$\mathrm{d}s^2 = Ac^2\mathrm{d}t^2 - \left(B\mathrm{d}r^2 + Cr^2\mathrm{d}\theta^2 + Dr^2\sin^2(\theta)\mathrm{d}\phi^2 + F\mathrm{d}r\mathrm{d}\theta + G\mathrm{d}r\mathrm{d}\phi + I\mathrm{d}\theta\mathrm{d}\phi\right) \tag{12.4.338}$$

Now if the system is indeed spherical, the equation of the metric must be invariant by the transformation $\mathrm{d}\phi = -\mathrm{d}\phi$ (the opposite would be known for a long time if this were not the case experimentally) and/or also for the transformation $\mathrm{d}\theta = -\mathrm{d}\theta$.

So for this to be correct, we see immediately that in the preceding relation we must impose:

$$F = G = I = 0 \tag{12.4.339}$$

So finally it only remains:

$$\mathrm{d}s^2 = Ac^2\mathrm{d}t^2 - (B\mathrm{d}r^2 + Cr^2\mathrm{d}\theta^2 + Dr^2\sin^2(\theta)\mathrm{d}\phi^2) \tag{12.4.340}$$

where A, B, C, D will obviously be independent of time (the opposite would contradict our initial constraint) but may by symmetry of the sphere be dependent of r such that:

$$\mathrm{d}s^2 = A(r)c^2\mathrm{d}t^2 - (B(r)\mathrm{d}r^2 + C(r)r^2\mathrm{d}\theta^2 + D(r)r^2\sin^2(\theta)\mathrm{d}\phi^2) \tag{12.4.341}$$

Remark

Often in the literature, when deriving the famous Schwarzschild solution the metric can be cast in two equivalent ways:

$$\begin{aligned}\mathrm{d}s^2 &= e^{2\alpha(r,t)}\mathrm{d}t^2 - e^{2\beta(r,t)}\mathrm{d}r^2 - r^2\mathrm{d}\Omega^2\\ \mathrm{d}s^2 &= A(r,t)\mathrm{d}t^2 - B(r,t)\mathrm{d}r^2 - r^2\mathrm{d}\Omega^2\end{aligned} \quad (12.4.342)$$

The reason of the exponentials is in the idea to avoid negative input (the exponential function is never negative for real input) and keep the manifold Lorentzian.

Now, let us imagine be on the sphere (rigorously it is a hypersphere but it helps anyway...) at a fixed distance r from the center of the source of the field at a given instant t fixed. We then only have:

$$\mathrm{d}s^2 = C(r)r^2\mathrm{d}\theta^2 + D(r)r^2\sin^2(\theta)\mathrm{d}\phi^2 \quad (12.4.343)$$

since $\mathrm{d}t$ is zero (fixed time) and $\mathrm{d}r$ also (fixed distance r).

We have also on the way removed the sign $-$ because we anticipated that it will be eliminated in the third equality that will follow and we will put it then back.

Now, let us also imagine that we are close to the north pole of the sphere ($\theta = 0$), we then only have in first approximation:

$$\mathrm{d}s^2 \cong C(r)r^2\mathrm{d}\theta^2 \quad (12.4.344)$$

and at equator ($\theta = \pi/2$):

$$\mathrm{d}s^2 \cong D(r)r^2\mathrm{d}\phi^2 \quad (12.4.345)$$

By symmetry of the field, an infinitesimal angular displacement in each of these two particular zones must, however, be equal. From then on, we can only put (by spherical symmetry):

$$C(r) = D(r) \quad (12.4.346)$$

Hence the equation of the metric is reduced to:

$$\mathrm{d}s^2 \cong A(r)c^2\mathrm{d}t^2 - B(r)\mathrm{d}r^2 - C(r)r^2(\mathrm{d}\theta^2 + \sin^2(\theta)\mathrm{d}\phi^2) \quad (12.4.347)$$

Let us now show that we can choose a system of coordinates for which $C(r) = 1$.

Let us introduce for this a distance defined by:

$$\bar{r} = \sqrt{C(r)}r \quad (12.4.348)$$

hence:

$$C(r)r^2 = \bar{r}^2 \quad (12.4.349)$$

Therefore it comes:

$$\frac{\mathrm{d}(\bar{r}^2)}{\mathrm{d}r} = C'(r)r^2 + 2C(r)r \quad (12.4.350)$$

hence:

$$2\bar{r}\mathrm{d}\bar{r}=C'(r)r^2\mathrm{d}r+2C(r)r\mathrm{d}r=2C(r)r\mathrm{d}r\left[1+\frac{r}{2C(r)}C'(r)\right] \tag{12.4.351}$$

This is further simplified by:

$$\bar{r}\mathrm{d}\bar{r}=C(r)r\mathrm{d}r\left[1+\frac{r}{2C(r)}C'(r)\right] \tag{12.4.352}$$

Let's put it all to the square and divide it by left and right by $C(r)r^2=\bar{r}^2$:

$$(\mathrm{d}\bar{r})^2=C(r)(\mathrm{d}r)^2\left[1+\frac{r}{2C(r)}C'(r)\right]^2 \tag{12.4.353}$$

Therefore after rearranging a bit:

$$\mathrm{d}r^2=\frac{1}{C(r)}\left[1+\frac{r}{2C(r)}C'(r)\right]^2\mathrm{d}\bar{r}^2 \tag{12.4.354}$$

We get:

$$B\mathrm{d}r^2=\frac{B}{C(r)}\left[1+\frac{r}{2C(r)}C'(r)\right]^{-2}\mathrm{d}\bar{r}^2=B(\bar{r})\mathrm{d}\bar{r}^2 \tag{12.4.355}$$

Hence the equation of the metric can be written as:

$$\mathrm{d}s^2=A(\bar{r})c^2\mathrm{d}t^2-B(\bar{r})\mathrm{d}\bar{r}^2-\bar{r}^2(\mathrm{d}\theta^2+\sin^2(\theta)\mathrm{d}\phi^2) \tag{12.4.356}$$

It is therefore as if $C(r)=1$:

$$\mathrm{d}s^2=A(r)c^2\mathrm{d}t^2-B(r)\mathrm{d}\bar{r}^2-\bar{r}(\mathrm{d}\theta^2+\sin^2(\theta)\mathrm{d}\phi^2) \tag{12.4.357}$$

Therefore:

$$\mathrm{Diag}(g_{\mu\nu})=(A(r),-B(r),-r^2,-r^2\sin^2(\theta)) \tag{12.4.358}$$

Or explicitly:

$$g_{\mu\nu}=\begin{bmatrix}A(r)&0&0&0\\0&-B(r)&0&0\\0&0&-r^2&0\\0&0&0&-r^2\sin^2(\theta)\end{bmatrix} \tag{12.4.359}$$

And the corresponding contravariant metric tensor (that we will use further below) is then:

$$g^{\mu\nu}=\begin{bmatrix}1/A(r)&0&0&0\\0&-1/B(r)&0&0\\0&0&-1/r^2&0\\0&0&0&-1/(r^2\sin^2(\theta))\end{bmatrix} \tag{12.4.360}$$

such that for recall (see section Tensor Calculus page 2050):

$$g^{\mu\nu}g_{\mu\nu}=\delta^{\mu}_{\nu} \tag{12.4.361}$$

Now, to determine the remaining coefficients (that is, A and B) we are going to use the relation that must satisfy metric if it is locally of the Minkowski type:

$$R_{\mu\nu}=R^{\alpha}_{\mu\alpha\nu}=R^{\alpha}_{\mu,\alpha\nu}=0 \tag{12.4.362}$$

and therefore the first Bianchi's identity (see section Tensor Calculus page 2126) will be automatically satisfied.

Either in a developed form (see section Tensor Calculus page 2122):

$$\begin{aligned}R^{\alpha}_{\mu,\alpha\nu}&=\partial_{\alpha}\Gamma^{\alpha}_{\mu\nu}-\partial_{\nu}\Gamma^{\alpha}_{\mu\alpha}+\Gamma^{\beta}_{\mu\nu}\Gamma^{\alpha}_{\alpha\beta}-\Gamma^{\beta}_{\mu\alpha}\Gamma^{\alpha}_{\nu\beta}\\&=\Gamma^{\alpha}_{\mu\nu,\alpha}-\Gamma^{\alpha}_{\mu\alpha,\nu}+\Gamma^{\alpha}_{\mu\alpha,\nu}+\Gamma^{\beta}_{\mu\nu}\Gamma^{\beta}_{\alpha\beta}\Gamma^{\alpha}_{\nu\beta}=0\end{aligned} \tag{12.4.363}$$

with obviously (see section Tensor Calculus page 2109):

$$\Gamma^{i}_{kj}=\frac{1}{2}g^{il}\left(\partial_k g_{lj}+\partial_j g_{kl}-\partial_l g_{kj}\right)=\frac{1}{2}g^{il}\left(g_{lj,k}+g_{kl,j}-g_{kj,l}\right) \tag{12.4.364}$$

That is to say that we have quite a lot of work to do... OK! First since the metric is simple the only non-zero derivatives are:

$$g_{tt,r}=A' \qquad g_{rr,r}=-B' \qquad g_{\theta\theta,r}=-2r \tag{12.4.365}$$

$$g_{\varphi\varphi,r}=-2r\sin^2(\theta) \qquad g_{\varphi\varphi,\theta}=-2r^2\sin(\theta)\cos(\theta) \tag{12.4.366}$$

We then simply deduce the 9 non-zero elements of the connection (the details are given following the request of a reader):

$$\begin{aligned}\Gamma^{\theta}_{\theta r}=\Gamma^{\theta}_{r\theta}&=\frac{1}{2}g^{\theta l}\left(g_{lr,\theta}+g_{\theta l,r}-g_{\theta r,l}\right)\\&=\frac{1}{2}\left[\begin{array}{l}g^{\theta t}\left(g_{tr,\theta}+g_{\theta t,r}-g_{\theta r,t}\right)+g^{\theta r}\left(g_{rr,\theta}+g_{\theta r,r}-g_{\theta r,r}\right)+g^{\theta\theta}\left(g_{\theta r,\theta}+g_{\theta\theta,r}-g_{\theta r,\theta}\right)\\+g^{\theta\varphi}\left(g_{\varphi r,\theta}+g_{\theta\varphi,r}-g_{\theta r,\varphi}\right)\end{array}\right]\\&=\frac{1}{2}\left[\begin{array}{l}0\cdot\left(g_{tr,\theta}+g_{\theta t,r}-g_{\theta r,t}\right)+0\cdot\left(g_{rr,\theta}+g_{\theta r,r}-g_{\theta r,r}\right)-\dfrac{1}{r^2}\left(g_{\theta r,\theta}+g_{\theta\theta,r}-g_{\theta r,\theta}\right)\\+0\cdot\left(g_{\varphi r,\theta}+g_{\theta\varphi,r}-g_{\theta r,\varphi}\right)\end{array}\right]\\&=-\frac{1}{r^2}\left(g_{\theta r,\theta}+g_{\theta\theta,r}-g_{\theta r,\theta}\right)=-\frac{1}{r^2}\left(0+(-2r)-0\right)=\frac{1}{r}\end{aligned} \tag{12.4.367}$$

$$\begin{aligned}\Gamma^{r}_{\varphi\varphi}&=\frac{1}{2}g^{rl}\left(g_{l\varphi,\varphi}+g_{\varphi l,\varphi}-g_{\varphi\varphi,l}\right)\\&=\frac{1}{2}\left[\begin{array}{l}g^{rt}\left(g_{t\varphi,\varphi}+g_{\varphi t,\varphi}-g_{\varphi\varphi,t}\right)+g^{rr}\left(g_{r\varphi,\varphi}+g_{\varphi r,\varphi}-g_{\varphi\varphi,r}\right)+g^{r\theta}\left(g_{\theta\varphi,\varphi}+g_{\varphi\theta,\varphi}-g_{\varphi\varphi,\theta}\right)\\+g^{r\varphi}\left(g_{\varphi\varphi,\varphi}+g_{\varphi\varphi,\varphi}-g_{\varphi\varphi,\varphi}\right)\end{array}\right]\\&=\frac{1}{2}\left[\begin{array}{l}0\cdot\left(g_{t\varphi,\varphi}+g_{\varphi t,\varphi}-g_{\varphi\varphi,t}\right)-\dfrac{1}{B}\left(g_{r\varphi,\varphi}+g_{\varphi r,\varphi}-g_{\varphi\varphi,r}\right)-0\cdot\left(g_{\theta\varphi,\varphi}+g_{\varphi\theta,\varphi}-g_{\varphi\varphi,\theta}\right)\\+0\cdot\left(g_{\varphi\varphi,\varphi}+g_{\varphi\varphi,\varphi}-g_{\varphi\varphi,\varphi}\right)\end{array}\right]\\&=-\frac{1}{2B}\left(g_{r\varphi,\varphi}+g_{\varphi r,\varphi}-g_{\varphi\varphi,r}\right)=-\frac{1}{2B}\left(0+0-\left(-2r\sin^2(\theta)\right)\right)=-\frac{r\sin^2(\theta)}{B}\end{aligned} \tag{12.4.368}$$

$$\begin{aligned}
\Gamma^{r}_{tt} &= \frac{1}{2} g^{rl}\left(g_{lt,t}+g_{tl,t}-g_{tt,l}\right) \\
&= \frac{1}{2}\left[\begin{aligned} & g^{rt}\left(g_{tt,t}+g_{tt,t}-g_{tt,t}\right)+g^{rr}\left(g_{rt,t}+g_{tr,t}-g_{tt,r}\right)+g^{r\theta}\left(g_{\theta t,t}+g_{t\theta,t}-g_{tt,\theta}\right) \\ & +g^{r\varphi}\left(g_{\varphi t,t}+g_{t\varphi,t}-g_{tt,\varphi}\right)\end{aligned}\right] \\
&= \frac{1}{2}\left[\begin{aligned} & 0\cdot\left(g_{tt,t}+g_{tt,t}-g_{tt,t}\right)+\frac{1}{A}\left(g_{rt,t}+g_{tr,t}-g_{tt,r}\right)+0\cdot\left(g_{\theta t,t}+g_{t\theta,t}-g_{tt,\theta}\right) \\ & +0\cdot\left(g_{\varphi t,t}+g_{t\varphi,t}-g_{tt,\varphi}\right)\end{aligned}\right] \\

&= -\frac{1}{2r^2\sin^2(\theta)}\left(g_{\varphi r,\varphi} + g_{\varphi\varphi,r} - g_{\varphi r,\varphi}\right) = -\frac{1}{2r^2\sin^2(\theta)}\left(0 + -2r\sin^2(\theta) - 0\right) = \frac{1}{r}
\end{aligned}
\tag{12.4.374}
$$

$$\begin{aligned}
\Gamma_{\varphi\varphi}^{\theta} &= \frac{1}{2} g^{\theta l}\left(g_{l\varphi,\varphi}+g_{\varphi l,\varphi}-g_{\varphi\varphi,l}\right) \\
&= \frac{1}{2}\left[\begin{array}{l} g^{\theta t}\left(g_{t\varphi,\varphi}+g_{\varphi t,\varphi}-g_{\varphi\varphi,t}\right)+g^{\theta r}\left(g_{r\varphi,\varphi}+g_{\varphi r,\varphi}-g_{\varphi\varphi,r}\right)+g^{\theta\theta}\left(g_{\theta\varphi,\varphi}+g_{\varphi\theta,\varphi}-g_{\varphi\varphi,\theta}\right) \\ +g^{\theta\varphi}\left(g_{\varphi\varphi,\varphi}+g_{\varphi\varphi,\varphi}-g_{\varphi\varphi,\varphi}\right) \end{array}\right] \\
&= \frac{1}{2}\left[\begin{array}{l} 0\cdot\left(g_{t\varphi,\varphi}+g_{\varphi t,\varphi}-g_{\varphi\varphi,t}\right)+0\cdot\left(g_{r\varphi,\varphi}+g_{\varphi r,\varphi}-g_{\varphi\varphi,r}\right)-\dfrac{1}{r^2}\left(g_{\theta\varphi,\varphi}+g_{\varphi\theta,\varphi}-g_{\varphi\varphi,\theta}\right) \\ +0\cdot\left(g_{\varphi\varphi,\varphi}+g_{\varphi\varphi,\varphi}-g_{\varphi\varphi,\varphi}\right) \end{array}\right] \\
&= -\frac{1}{2r^2}\left(g_{\theta\varphi,\varphi}+g_{\varphi\theta,\varphi}-g_{\varphi\varphi,\theta}\right) = -\frac{1}{2r^2}\left(0+0-\left(-2r^2\sin(\theta)\cos(\theta)\right)\right) = -\sin(\theta)\cos(\theta)
\end{aligned} \tag{12.4.375}$$

To summarize (we have taken the results with the signature $(-,+,+,+)$ of the metric instead of $(+,-,-,-)$ to conform ourselves to the tradition but this does not change the final result):

$$\begin{gathered}
\Gamma_{tr}^{t}=\Gamma_{rt}^{t}=A'/2A \qquad \Gamma_{tt}^{r}=-A'/2B \qquad \Gamma_{rr}^{r}=-B'/2B \\
\Gamma_{\theta r}^{\theta}=\Gamma_{r\theta}^{\theta}=-1/r \qquad \Gamma_{\theta\theta}^{r}=r/B \qquad \Gamma_{\varphi r}^{\varphi}=\Gamma_{r\varphi}^{\varphi}=-1/r \\
\Gamma_{\varphi\varphi}^{r}=r\sin^2(\theta)/B \qquad \Gamma_{\varphi\theta}^{\varphi}=\Gamma_{\theta\varphi}^{\varphi}=-\cot(\theta) \qquad \Gamma_{\varphi\varphi}^{\theta}=\sin(\theta)\cos(\theta)
\end{gathered} \tag{12.4.376}$$

Now that we have these terms of the connection, we have to calculate their derivative in order to be able to express the first two terms of:

$$R_{\mu\nu}=R_{\mu,\alpha\nu}^{\alpha}=\Gamma_{\mu\nu,\alpha}^{\alpha}-\Gamma_{\mu\alpha,\nu}^{\alpha}+\Gamma_{\mu\nu}^{\beta}\Gamma_{\alpha\beta}^{\alpha}-\Gamma_{\mu\alpha}^{\beta}\Gamma_{\nu\beta}^{\alpha}=0 \tag{12.4.377}$$

There are then 10 non-zero terms which are:

$$\begin{aligned}
&\Gamma_{tr,r}^{t}=\Gamma_{rt,r}^{t}=-\frac{A''}{2A}+\frac{A'^2}{2A^2} && \Gamma_{tt,r}^{r}=-\frac{A''}{2B}+\frac{A'B'}{2B^2} \\
&\Gamma_{rr,r}^{r}=-\frac{B''}{2B}+\frac{B'^2}{2B^2} && \Gamma_{\theta r,r}^{\theta}=\Gamma_{r\theta,r}^{\theta}=\frac{1}{r^2} \\
&\Gamma_{\theta\theta,r}^{r}=\frac{1}{B}-\frac{rB'}{B^2} && \Gamma_{\varphi r,r}^{\varphi}=\Gamma_{r\varphi,r}^{\varphi}=\frac{1}{r^2} \\
&\Gamma_{\varphi\varphi,r}^{r}=\frac{\sin^2(\theta)}{B}-\frac{r\sin^2(\theta)B'}{B^2} && \Gamma_{\varphi\theta,\theta}^{\varphi}=\Gamma_{\theta\varphi,\theta}^{\varphi}=\frac{1}{\sin^2(\theta)} \\
&\Gamma_{\varphi\varphi,\theta}^{r}=\frac{r2\sin(\theta)\cos(\theta)}{B} && \Gamma_{\varphi\varphi,\theta}^{\theta}=\cos^2(\theta)-\sin^2(\theta)
\end{aligned} \tag{12.4.378}$$

We finally have for each component of the Ricci tensor:

$$\begin{aligned}
R_{tt} &= \left(\frac{A''}{2B}+\frac{A'B'}{2B^2}\right)-(0)+\left(\frac{A'^2}{2AB}\right)-\left(\frac{A'^2}{4AB}+\frac{A'B'}{4B^2}+\frac{A'}{rB}\right)=-\frac{A''}{2B}+\frac{A'^2}{4AB}+\frac{A'B'}{4B^2}-\frac{A'}{rB}\\
R_{rr} &= \left(-\frac{B''}{2B}+\frac{B'^2}{2B^2}\right)-\left(-\frac{A''}{2A}+\frac{A'^2}{2A^2}-\frac{B''}{2B}\right)+\left(\frac{A'^2}{4A^2}+\frac{B'^2}{4B^2}+\frac{2}{r^2}\right)-\left(\frac{A'B'}{4AB}+\frac{B'^2}{4B^2}+\frac{B'}{rB}\right)\\
&=\frac{A''}{2A}-\frac{A'^2}{4A^2}-\frac{A'B'}{4AB}-\frac{B'}{rB}\\
R_{\theta\theta} &= \left(\frac{1}{B}-\frac{rB'}{B^2}\right)-\left(\frac{1}{\sin^2(\theta)}\right)+\left(-\frac{2}{B}+\cot^2(\theta)\right)-\left(-\frac{A'r}{2AB}-\frac{B'r}{2B^2}-\frac{2}{B}\right)=\frac{A'r}{2AB}-\frac{rB'}{2B^2}+\frac{1}{B}-1\\
R_{\varphi\varphi} &= \left(\sin^2\left[\frac{1}{B}-r\frac{B'}{B^2}-2\right]+1\right)-(0)+\left(-\sin^2(\theta)\left[\frac{2}{B}-2\right]-2\right)\\
&-\left(-\sin^2(\theta)\left[\frac{A'r}{2AB}+\frac{B'r}{2B^2}+\frac{2}{B}-1\right]-1\right)=\sin^2(\theta)\left[\frac{A'r}{2AB}-\frac{B'r}{2B^2}+\frac{1}{B}-1\right]\\
R_{r\theta} &= (0)-(0)+\left(\frac{\cot(\theta)}{r}\right)-\left(\frac{\cot(\theta)}{r}\right)=0
\end{aligned} \tag{12.4.379}$$

The only elements directly non-zero are then:

$$\begin{aligned}
R_{tt} &= -\frac{A''}{2B}+\frac{A'^2}{4AB}+\frac{A'B'}{4B^2}-\frac{A'}{rB}=0\\
R_{rr} &= \frac{A''}{2A}-\frac{A'^2}{4A^2}-\frac{A'B'}{4AB}-\frac{B'}{rB}=0\\
R_{\theta\theta} &= \frac{A'r}{2AB}-\frac{rB'}{2B^2}+\frac{1}{B}-1=0\\
R_{\varphi\varphi} &= \sin^2(\theta)\left[\frac{A'r}{2AB}-\frac{B'r}{2B^2}+\frac{1}{B}-1\right]=\sin^2(\theta)R_{\theta\theta}=0
\end{aligned} \tag{12.4.380}$$

In a more conventional form (according to the literature) we can simplify a little and moreover keep only the first three equations:

$$\begin{aligned}
R_{tt} &= -2rA\partial_r^2(A)B+r\partial_r(A)^2B+rA\partial_r(A)\partial_r(B)-4A\partial_r(A)B=0\\
R_{rr} &= 2rA\partial_r^2(A)B-r\partial_r(A)^2B-rA\partial_r(A)\partial_r(B)-4A^2\partial_r(B)=0\\
R_{\theta\theta} &= r\partial_r(A)B-r\partial_r(B)A+2AB-2AB^2=0
\end{aligned} \tag{12.4.381}$$

If we add the first two equations, we have:

$$\partial_r(A)B+A\partial_r(B)=0 \tag{12.4.382}$$

which equals:

$$\partial_r(A\cdot B)=\partial_r(A)B+A\partial_r(B)=0 \tag{12.4.383}$$

And this also gives us:

$$\partial_r(A)B=-A\partial_r(B) \tag{12.4.384}$$

We have therefore:

$$R_{\theta\theta}=r\partial_r(A)B-r\partial_r(B)A+2AB-2AB^2=0 \tag{12.4.385}$$

which becomes:

$$\begin{aligned}&r\left(\partial_r(A)B-A\partial_r(B)\right)+2AB-2AB^2=0\\&\Rightarrow r\left(-\partial_r(B)A-\partial_r(B)A\right)+2AB-2AB^2=0\\&\Rightarrow -r\partial_r(B)+B(1-B)=0\\&\Rightarrow r\partial_r B(r)=B(r)\Big(1-B(r)\Big)\end{aligned}\tag{12.4.386}$$

Where we have divide by $2A$ when passing from the second to the third line.

The reader can verify that a solution of the differential equation is (we can provide the details on request):

$$B(r)=\left(1+\frac{1}{S\cdot r}\right)^{-1}\tag{12.4.387}$$

Where S is a non-zero real constant. Consequently, the metric for a static solution, symmetrically spherical and in the vacuum (...), is written:

$$\mathrm{d}s^2=A(r)c^2\mathrm{d}t^2-\left(1+\frac{1}{S\cdot r}\right)^{-1}\mathrm{d}r^2-r^2\left(\mathrm{d}\theta^2+\sin^2(\theta)\mathrm{d}\phi^2\right)\tag{12.4.388}$$

It remains for us to determine a coefficient. But as:

$$\partial_r\left(A\cdot B\right)=0\tag{12.4.389}$$

It comes:

$$A\cdot B=K=c^{te}\tag{12.4.390}$$

Hence:

$$A=\frac{K}{B}=K\left(1+\frac{1}{S\cdot r}\right)\tag{12.4.391}$$

Finally:

$$\mathrm{d}s^2=K\left(1+\frac{1}{S\cdot r}\right)c^2\mathrm{d}t^2-\left(1+\frac{1}{S\cdot r}\right)^{-1}\mathrm{d}r^2-r^2\left(\mathrm{d}\theta^2+\sin^2(\theta)\mathrm{d}\phi^2\right)\tag{12.4.392}$$

Let us notice that the space-time represented by this metric is asymptotically flat, or, in other words, when $r\rightarrow+\infty$ the metric approaches that of Minkowski and the space-time variety resembles to that of the Minkowski's space.

To calculate the constants K and S, we use the weak field approximation. In other words, we place ourselves far from the center, where the gravitational field is weak. In this case, the component g_{tt} of the metric can be calculated.

Indeed, we had studied the Newtonian limit earlier above (see page 5751) and obtained the following relation:

$$g_{00}=\eta_{00}+h_{00}=(1-\varphi)=\left(1-\frac{2GM}{rc^2}\right)\tag{12.4.393}$$

So in extenso we can put without too much fear:

$$g_{00}=K\left(1+\frac{1}{S\cdot r}\right)=\left(1-\frac{2GM}{rc^2}\right) \tag{12.4.394}$$

Therefore:

$$K=1 \qquad \text{and} \qquad \frac{1}{S}=-\frac{2GM}{c^2} \tag{12.4.395}$$

Finally we have for the "Schwarzschild metric":

$$\boxed{\mathrm{d}s^2=\left(1-\frac{2GM}{c^2r}\right)c^2\mathrm{d}t^2-\frac{1}{\left(1-\dfrac{2GM}{c^2r}\right)}\mathrm{d}r^2-r^2\left(\mathrm{d}\theta^2+\sin^2(\theta)\mathrm{d}\phi^2\right)} \tag{12.4.396}$$

That is to say in natural units:

$$\mathrm{d}s^2=\left(1-\frac{2GM}{r}\right)\mathrm{d}t^2-\frac{1}{\left(1-\dfrac{2GM}{r}\right)}\mathrm{d}r^2-r^2\left(\mathrm{d}\theta^2+\sin^2(\theta)\mathrm{d}\phi^2\right) \tag{12.4.397}$$

What ultimately gives the Schwarzschild metric tensor in natural units:

$$g_{\mu\nu}=\begin{bmatrix} 1-\dfrac{2GM}{rc^2} & 0 & 0 & 0 \\ 0 & -\left(1-\dfrac{2GM}{rc^2}\right)^{-1} & 0 & 0 \\ 0 & 0 & -r^2 & 0 \\ 0 & 0 & 0 & -r^2\sin^2(\theta) \end{bmatrix} \tag{12.4.398}$$

Or in SI units:

$$g_{\mu\nu}=\begin{bmatrix} c^2-\dfrac{2GM}{r} & 0 & 0 & 0 \\ 0 & -\left(1-\dfrac{2GM}{rc^2}\right)^{-1} & 0 & 0 \\ 0 & 0 & -r^2 & 0 \\ 0 & 0 & 0 & -r^2\sin^2(\theta) \end{bmatrix} \tag{12.4.399}$$

Notice that when $M=0$ we fall back on the Minkowski metric!

Caution!!! Some reference books have the Schwarzschild metric with different signs because they take the metric $(-,+,+,+)$ instead of the metric $(+,-,-,-)$.

The Schwarzschild metric is a solution of Einstein's field equations in empty space (assumed as because we will see during study of quantum field theory that there are not such things as "empty space"), meaning that it is valid only outside the gravitating body. That is, for a spherical body of radius R the solution is valid for $r>R$. To describe the gravitational field both inside and outside the gravitating body the Schwarzschild solution must be matched with some suitable interior solution at $r=R$, such as the "interior Schwarzschild solution".

And all (physically) apparent singularity appears when (this leads also the time component g_{11} to freeze - time is infinitely dilated - as it is then equal to zero!):

$$\left(1-\frac{2GM}{c^2r}\right)=0 \tag{12.4.400}$$

This leads indeed the component g_{22} to be equal to infinity! Or in other words, this is equivalent to the coordinate of the radius r to be equal to:

$$\boxed{r=\frac{2GM}{c^2}} \tag{12.4.401}$$

This radius, which we had already determined during our study of Classical Mechanics, is named the "Schwarzschild radius".

Therefore the Schwarzschild solution appears to have singularities at $r=0$ and $r=2GM/c^2$; some of the metric components "blow up" at these radii. Since the Schwarzschild metric is only expected to be valid for radii larger than the radius R of the gravitating body, there is no problem as long as $R>2GM/c^2$. For ordinary stars and planets this is always the case. For example, the radius of the Sun (actually a G2V-type star, aka yellow dwarf) is approximately $700,000$ [km], while its Schwarzschild radius is only 3 [km].

The Schwarzschild radius is defined as the critical radius provided by the Schwarzschild geometry, below which nothing can escape: if a star or other object reaches a radius equal to or less than its Schwarzschild radius then it becomes a "Black Hole", and any object approaching at a distance from it less than the Schwarzschild's ray will not escape from it. The term is used in physics and astronomy to give an order of magnitude of the characteristic size to which General Relativity effects become necessary for the description of objects of a given mass. The only objects that are not Black Holes and whose size is of the same order as their Schwarzschild radius are neutron stars (or pulsars), thus, curiously, also the observable Universe as a whole...

If we come back to the metric:

$$\mathrm{d}s^2=-\left(1-\frac{2GM}{c^2r}\right)c^2\mathrm{d}t^2+\left(1-\frac{2GM}{c^2r}\right)^{-1}\mathrm{d}r^2+r^2\left(d\theta^2+\sin^2\theta\mathrm{d}\phi^2\right) \tag{12.4.402}$$

notice that, in the metric, coefficients multiplying $\mathrm{d}t^2$ and $\mathrm{d}r^2$ switch signs when r becomes smaller than r_s. This means that, in a way, radial and temporal coordinates have switched their roles as space and time coordinates below the Black Hole horizon!

This also means that r will inevitably grow smaller for unfortunate space traveller who crossed the event horizon, just like e.g. t inevitably grows bigger for anybody in flat space-time. The center of black hole stops being something "over there" once you crossed the horizon, it literally becomes your future.

Definitions (#12.4.545):

D1. A "singularity" is a mathematical entity whose calculation reach infinity because of a division by zero. As we have seen it in the section Analysis (see page 2276), singularities (i.e. "discontinuities") in the field of functional analysis are often also named "singular points". Isolated singularities may be classified as "poles", "essential singularities", "logarithmic singularities", or "removable singularities".

D2. An "apparent singularity", also named coordinate singularity", is a singularity that exists only because of the arbitrary choice of a coordinate system (i.e. a singular point where the general solution is holomorphic[48]).

Remarks

R1. The singularity in the metric when the Schwarzschild radius is reached is apparent because it is only an effect of the coordinate system used. It is an instance of what is named a "coordinate singularity". As the name implies, the singularity arises from a bad choice of coordinates or coordinate conditions. When changing to a different coordinate system (for example Lemaître coordinates, Eddington–Finkelstein coordinates, Kruskal–Szekeres coordinates, Novikov coordinates, or Gullstrand–Painlevé coordinates) the metric becomes regular at $r=2GM/c^2$

R2. A remarkable theorem states that the Schwarzschild metric is the only solution to Einstein's equations in vacuum possessing spherical symmetry. As the Schwarzschild metric is also static, this shows that in fact in vacuum any spherical solution is automatically static. One interesting consequence of this theorem is that any pulsating star that remains spherically symmetrical can not generate gravitational waves (since the space-time region outside the star must remain static).

R3. As the previous developments are based on the assumption of mathematical tools (Bianchi's identity) that requires a zero torsion tensor (see section Tensor Calculus page 2123), i.e. "torsion-free", there are more complete models that can not by extension use the Einstein equation of fields. If we drop the torsion-less connection requirement, we get a more general theory, the "Einstein-Cartan" one (Einstein-Cartan theory is an intermediary step to supergravity models, there is also the Poincare gauge theories of Hehl).

Now that we have the Schwarzschild metric we come back to the Schild criterion that we saw in our classical study of the Einstein effect.

If we rewrite the Schwarzschild metric for a static body, we have the metric which is simplified into:

$$\mathrm{d}s^2=\left(1-\frac{2GM}{c^2r}\right)c^2\mathrm{d}t^2 \qquad (12.4.403)$$

By using the gravitational potential (see section Astronomy page 5266):

$$\varphi=\frac{GM}{r}\;[\mathrm{J}\cdot\mathrm{kg}^{-1}] \qquad (12.4.404)$$

The metric is written:

$$\mathrm{d}s^2=\left(1-\frac{2\varphi}{c^2}\right)c^2\mathrm{d}t^2 \qquad (12.4.405)$$

---

[48] For reminder a "holomorphic function" is complex-valued function of one or more complex variables that is complex differentiable in a neighbourhood of each point in a domain in complex coordinate space

hence by introducing the proper time:

$$c^2\mathrm{d}\tau^2=\left(1-\frac{2\varphi}{c^2}\right)c^2\mathrm{d}t^2 \quad (12.4.406)$$

hence:

$$\mathrm{d}\tau=\left(1-\frac{2\varphi}{c^2}\right)^{1/2}\mathrm{d}t \quad (12.4.407)$$

Therefore:

$$\mathrm{d}t=\left(1-\frac{2\varphi}{c^2}\right)^{-1/2}\mathrm{d}\tau \quad (12.4.408)$$

Maclaurin's second-order expansion in series (see section Sequences and Series page 1703) of the negative root gives:

$$\mathrm{d}t\cong\left(1+\frac{\varphi}{c^2}\right)\mathrm{d}\tau \quad (12.4.409)$$

Therefore we have:

$$\mathrm{d}t\cong\left(1+\frac{\varphi}{c^2}\right)\mathrm{d}\tau\geq\mathrm{d}\tau \quad (12.4.410)$$

Thus, this proof that the curvature (gravitation) generates a larger time dilation (in the sense that it flows faster) that the field of gravity is intense (mass M is large) or that we are close to the body under the influence of the field (small radius r).

For the Earth, the term:

$$\varphi=\frac{GM}{r} \quad (12.4.411)$$

is relatively small. But for a Black Hole or a neutron star, this is no longer the case and the dilation becomes important and the effects accessible to the measure.

12.4.6 Empirical evidence of General Relativity theory

We will now review the 5 classical experimental checks of the 120th century (holocene calendar) of the General Relativity theory which are:

1. The precession of the perihelion which, in terms of numerical results, posed a problem for us with the tools of Classical Mechanics (see section Astronomy page 5361).
2. The deflection of electromagnetic waves (light) passing close to a massive stellar body which in the numerical results also posed a problem to us with the tools of Classical Mechanics (see section Astronomy page 5358).
3. The proof of the Schild criterion (already made in the preceding paragraphs) as the only way to explain rigorously the gravitational redshift and the hypothesis of slowing down time in a gravitational field.

4. The delay of electromagnetic signals propagating near dense bodies. Delay referred to as "Shapiro effect" whose numerical applications are used for the operation of the G.P.S and which will be discussed later.
5. The detection of gravitational waves in the early 121st century (holocene calendar).
6. The first imagery of Black Hole shadows in the early 121st century (holocene calendar).

We will add to this list (when we will have the time...) the derivations of the Lense-Thirring effect of space-time dragging around rotating celestial objects confirmed with very high accuracy by multiple probes like Gravity Probe B, LARES and GRACE and the time decay of binary system (like the he Hulse-Taylor binary system composed of a neutron star and a pulsar which orbit around their common center of mass) that also confirms General Relativity with a very high accuracy!

12.4.6.1 Gravitational Redshift

We know very good that in the non inertial Earth's referential frame, the space time line element between the two events can be written as:

$$\mathrm{d}s^2=g_{\mu\nu}\mathrm{d}x^\mu\mathrm{d}x^\nu \qquad (12.4.412)$$

But as the observer is at rest in his own referential, the only non null coordinates is x_0, so that the square of the line element can be simplified to:

$$\mathrm{d}s^2=g_{00}(\mathrm{d}x^0)^2=g_{00}(c\mathrm{d}t)^2=g_{00}c^2\mathrm{d}t^2 \qquad (12.4.413)$$

If our observer is at rest in his own referential, we know also how to express the space time distance with respect to the proper time τ:

$$\mathrm{d}s^2=c^2\mathrm{d}\tau^2 \qquad (12.4.414)$$

And therefore:

$$c^2\mathrm{d}\tau^2=g_{00}c^2\mathrm{d}t^2 \qquad (12.4.415)$$

That is:

$$\mathrm{d}\tau=\sqrt{g_{00}}\mathrm{d}t \qquad (12.4.416)$$

But we have also proved earlier that in the weak static field approximation:

$$g_{00}=\eta_{00}+h_{00}=1-\frac{2\varphi}{c^2}=1-\frac{2GM}{c^2r} \qquad (12.4.417)$$

Therefore:

$$\mathrm{d}\tau=\sqrt{1-\frac{2GM}{c^2r}}\mathrm{d}t<\mathrm{d}t \qquad (12.4.418)$$

We can then write:

$$\boxed{\mathrm{d}t=\frac{\mathrm{d}\tau}{\sqrt{1-\dfrac{2GM}{c^2r}}}} \tag{12.4.419}$$

This equation tells us that clocks run slower in a gravitational field as seen by a distant observer, this effect is known as "gravitational time dilation" or "gravitational redshift"!

There are a few quite solid experimental direct evidence of the gravitational time dilation like those based on optic clocks (see [99] or [99] or [138]) and especially the Pound–Rebka experiment that is considered as a definitive proof.

As a direct consequence, because frequency is the reciprocal of the period (time interval), we have:

$$\boxed{f_\infty=f_g\sqrt{1-\frac{2GM}{c^2r}}} \tag{12.4.420}$$

where f_∞ is the frequency of the wave as measured by a distant observer of a static and weak gravitational source and f_g is the frequency of the wave measured at the point where the is a gravitational source.

This equation tells us that the frequency of a wave as recorded by a distant observer is less than the frequency recorded by an observer located where the events occurred in the gravitational field. This phenomenon is known as the "gravitational redshift", because a reduction in frequency means a shift toward the longer wavelengths or red end of the electromagnetic spectrum.

We can think of the photons losing energy as they climb out of the gravitational field - loss of energy equating to drop in frequency.

If the atom is at the event horizon of a Black Hole $r=2GM/c^2$, the detected frequency of the photon becomes zero. If the atom was just above the event horizon, the frequency would be finite, but extremely large. But large wavelength means small frequency, which means small energy, which will escape detection if it is small enough. Therefore, no light can be emitted or reflected from the event horizon of Black Hole. The effect is the same also for all other forms of radiation and signals, since they all need to “climb up” an infinite gravitational potential well if they start from the horizon. Therefore, since no radiation or signals can ever come out of the event horizon, Black Hole is indeed black....

A more realistic scenario is that the second observer is itself under the effect of the gravitational field.

Let’s assume that the observer A pointing the torch stands at the surface of the Earth at a distance r_a from the center of the Earth and that the second observer B stands by example at the top of a tower at the distance $r_b=r_a+\delta h$ with δh very small in comparison to r_a.

We can then write:

$$f_\infty=f_A\sqrt{1-\frac{2GM}{c^2r_A}}\cong f_A\sqrt{1-\frac{2GM}{c^2r_B}} \tag{12.4.421}$$

Therefore:

$$f_B = f_A \frac{\sqrt{1-\dfrac{2GM}{c^2 r_A}}}{\sqrt{1-\dfrac{2GM}{c^2 r_B}}} \tag{12.4.422}$$

Let us now use the Schwarzschild radius notation:

$$f_B = f_A \frac{\sqrt{1-\dfrac{R_S}{r_A}}}{\sqrt{1-\dfrac{R_S}{r_B}}} \tag{12.4.423}$$

If we suppose as it is the case on Earth that $R_S \ll r_a$ and so that $R_S \ll r_b$, the redshift can be approximated by a Maclaurin first order expansion (see section Sequences and Series page 1703):

$$\sqrt{1+x} \cong 1+\frac{1}{2}x \qquad \text{and} \qquad \frac{1}{\sqrt{1+x}} \cong 1-\frac{1}{2}x \tag{12.4.424}$$

then:

$$f_B = f_A\left(1-\frac{R_s}{2r_A}\right)\left(1+\frac{R_s}{2r_A}\right) \tag{12.4.425}$$

Therefore:

$$f_B \cong f_A\left(1-\frac{R_S}{2r_A}+\frac{R_S}{2r_B}\right) \tag{12.4.426}$$

Finally:

$$\boxed{\frac{f_B-f_A}{f_A}=\frac{\Delta f}{f_A}\cong\frac{R_S}{2r_B}-\frac{R_S}{2r_A}} \tag{12.4.427}$$

Also written sometimes (according to $\Phi = GM/r$):

$$\boxed{z=\frac{\Delta f}{f_A}=\frac{\Delta\nu}{\nu_A}\cong\frac{\Phi_B}{c^2}-\frac{\Phi_A}{c^2}=\frac{\Phi_B-\Phi_A}{c^2}} \tag{12.4.428}$$

The effect is now considered to have been definitively verified by the experiments of Pound, Rebka and Snider between 11959 (holocene calendar) and 11965 (holocene calendar). The Pound–Rebka experiment of 11959 (holocene calendar) measured the gravitational redshift in spectral lines using a terrestrial ^{57}Fe gamma source over a vertical height of 22.5 [m].

A numerical application gives therefore for this experiment:

$$\frac{\Delta f}{f_A} \cong \frac{GM_T}{(R_T+22.5)c^2}-\frac{GM_T}{R_T c^2} \cong -2.45839\cdot 10^{-15}\,[\mathrm{s}^{-1}] \tag{12.4.429}$$

while Pound and Rebka have found:

$$\frac{\Delta f}{f_A} \cong -2.565\cdot 10^{-15}\,[\mathrm{s}^{-1}] \tag{12.4.430}$$

So first we see that $f_B < f_A$ so there is indeed a shift to the red. Secondly we have an average shift of the frequency to the red!

For the fun let us derive the expression of the formula for the gravitational red shift in the Newtonian limit using the properties of a photon.

In a gravitational field $\vec{g}$ a particle of mass m and velocity $\vec{v}$ changes it's energy E according to:

$$\frac{\mathrm{d}E}{\mathrm{d}t}=m\vec{g}\circ\vec{v}=\vec{g}\circ\vec{p} \tag{12.4.431}$$

For a massless photon described by its energy $E=h\nu=\hbar\omega$ and momentum $\vec{p}=\hbar\vec{k}$ this equation becomes after dividing by the Planck constant $\hbar$:

$$\frac{\mathrm{d}\omega}{\mathrm{d}t}=\vec{g}\circ\vec{k} \tag{12.4.432}$$

Inserting the gravitational field of a spherical body of mass M within the distance $\vec{r}$:

$$\vec{g}=-GM\frac{\vec{r}}{r^3} \tag{12.4.433}$$

and the wave vector of a photon leaving the gravitational field in radial direction:

$$\vec{k}=\frac{\omega}{c}\frac{\vec{r}}{r} \tag{12.4.434}$$

the energy equation becomes:

$$\frac{\mathrm{d}\omega}{\mathrm{d}t}=-\frac{GM}{c}\frac{\omega}{r^2} \tag{12.4.435}$$

Using $\mathrm{d}r=c\mathrm{d}t$ an ordinary differential equation which is only dependent on the radial distance r is obtained:

$$\frac{\mathrm{d}\omega}{\mathrm{d}r}=-\frac{GM}{c^2}\frac{\omega}{r^2} \tag{12.4.436}$$

For a photon starting at the surface of a spherical body with a Radius R_T with a frequency $\omega_0=2\pi\nu_0$ the analytical solution is:

$$\frac{\mathrm{d}\omega}{\mathrm{d}r}=-\frac{GM}{c^2}\frac{\omega}{r^2}\quad\Rightarrow\quad\omega(r)=\omega_0\exp\left(-\frac{GM}{c^2}\left(\frac{1}{R_T}-\frac{1}{r}\right)\right) \tag{12.4.437}$$

In a large distance from the body $r\rightarrow+\infty$ an observer measures the frequency :

$$\omega_{\text{obs}}=\omega_0\exp\left(-\frac{GM}{c^2}\left(\frac{1}{R_T}\right)\right)\cong\omega_0\left(1-\frac{GM}{R_Tc^2}+\frac{1}{2}\frac{G^2M^2}{R_T^2c^4}-\ldots\right) \tag{12.4.438}$$

Therefore, the red shift is:

$$z=\frac{\omega_0-\omega_{\text{obs}}}{\omega_{\text{obs}}}=\frac{1-\exp\left(-\frac{GM}{R_Tc^2}\right)}{\exp\left(-\frac{GM}{R_Tc^2}\right)} \tag{12.4.439}$$

In the linear approximation:

$$z=\frac{\frac{GM}{R_Tc^2}-\frac{1}{2}\frac{G^2M^2}{R_T^2e^4}+\ldots}{1-\frac{GM}{R_Tc^2}+\frac{1}{2}\frac{G^2M^2}{R_T^2c^4}-\ldots}\cong\frac{\frac{GM}{R_Tc^2}}{1-\frac{GM}{R_Tc^2}+\frac{1}{2}\frac{G^2M^2}{R_T^2c^4}-\ldots}\cong\frac{GM}{c^2R_T}\qquad(12.4.440)$$

the Newtonian limit for the gravitational red shift of General Relativity is obtained! For our example above, this gives:

$$\frac{\Delta f}{f_A}\cong\frac{GM_T}{R_Tc^2}\cong 6.9535\cdot 10^{-10}\,[\mathrm{s}^{-1}]\qquad(12.4.441)$$

So we see that the difference with the General Relativity case is quite huge...

12.4.6.2 Precession of Mercury's Perihelion

Let us now treat one of the most famous examples of General Relativity: the precession of the Mercury's perihelion (the same test and confirmation has been done using the VLT with a star orbiting the Milky Way central Black Hole in 12020 - holocene calendar) first shown by Urbain LeVerrier (see [342]). We had already dealt with this case in the Astronomy section (see page 5361), but we had mentioned that the theoretical numerical result did not correspond to the experimental observations. We shall see in the equivalent of almost ten A4 pages of detailed developments how General Relativity makes it possible to reconcile theory and experience.

To study this case, we will use the Lagrangian formalism seen in the section of Analytical Mechanics.

First, let us recall that we obtained for the metric of Schwarzschild:

$$\mathrm{d}s^2=\left(1-\frac{2GM}{c^2r}\right)c^2\mathrm{d}t^2-\frac{1}{\left(1-\frac{2GM}{c^2r}\right)}\mathrm{d}r^2-r^2\left(\mathrm{d}\theta^2+\sin^2(\theta)\mathrm{d}\phi^2\right)\qquad(12.4.442)$$

What we will write by dividing by $\mathrm{d}s^2$:

$$1=\left(1-\frac{2GM}{c^2r}\right)c^2\dot{t}^2-\frac{1}{\left(1-\frac{2GM}{c^2r}\right)}\dot{r}^2-r^2\left(\dot{\theta}^2+\sin^2(\theta)\dot{\phi}^2\right)\qquad(12.4.443)$$

And to abbreviate the notations, we put $l=GM/c^2$ such that:

$$1=\left(1-\frac{2l}{r}\right)c^2\dot{t}^2-\frac{1}{\left(1-\frac{2l}{r}\right)}\dot{r}^2-r^2\left(\dot{\theta}^2+\sin^2(\theta)\dot{\phi}^2\right)\qquad(12.4.444)$$

Now let us recall that (see section Analytical Mechanics page 3161) in natural units:

$$\delta S=\int\delta(\mathrm{d}s)=\int\delta(1\cdot\mathrm{d}s)=0\qquad(12.4.445)$$

So (it's very rude but it works ... This is physics!...):

$$\delta S=\int \delta\left[\left(1-\frac{2l}{r}\right)c^2\dot{t}^2-\frac{1}{\left(1-\dfrac{2l}{r}\right)}\dot{r}^2-r^2\left(\dot{\theta}^2+\sin^2(\theta)\dot{\phi}^2\right)\right]\mathrm{d}s=0 \tag{12.4.446}$$

Finally it means that the Lagrangian is:

$$L=\left(1-\frac{2l}{r}\right)c^2\dot{t}^2-\frac{1}{\left(1-\dfrac{2l}{r}\right)}\dot{r}^2-r^2\left(\dot{\theta}^2+\sin^2(\theta)\dot{\phi}^2\right) \tag{12.4.447}$$

The equations of Lagrange give us for the θ coordinate see section Analytical Mechanics page 3162):

$$\frac{\mathrm{d}}{\mathrm{d}s}\frac{\partial L}{\partial\dot{\theta}}=\frac{\partial L}{\partial\theta} \tag{12.4.448}$$

with therefore:

$$\frac{\partial L}{\partial\dot{\theta}}=-2r^2\dot{\theta} \tag{12.4.449}$$

Hence:

$$\frac{\mathrm{d}}{\mathrm{d}s}\frac{\partial L}{\partial\dot{\theta}}=-2r^2\ddot{\theta}-4r\dot{\theta}\dot{r} \tag{12.4.450}$$

and:

$$\frac{\partial L}{\partial\theta}=-2r^2\sin(\theta)\cos(\theta)\dot{\phi}^2 \tag{12.4.451}$$

From where finally for the coordinate θ:

$$\frac{\mathrm{d}}{\mathrm{d}s}(r^2\dot{\theta})=r^2\sin(\theta)\cos(\theta)\dot{\phi}^2 \tag{12.4.452}$$

Let us do the same for ϕ. First, we have:

$$\frac{\partial L}{\partial\dot{\theta}}=-2r^2\sin^2(\theta)\dot{\phi} \tag{12.4.453}$$

Therefore:

$$\frac{\partial L}{\partial\phi}=0 \tag{12.4.454}$$

And it comes immediately from the application of the Euler-Lagrange equation:

$$\frac{\mathrm{d}}{\mathrm{d}s}\left(r^2\sin^2(\theta)\dot{\phi}\right)=0 \tag{12.4.455}$$

Let us do the same for t:

$$\frac{\partial L}{\partial t}=2\left(1-\frac{2l}{r}\right)c^2\dot{t} \tag{12.4.456}$$

And it comes here also immediately:

$$\frac{\mathrm{d}}{\mathrm{d}s}\left[\left(1-\frac{2l}{r}\right)\dot{t}\right]=0 \tag{12.4.457}$$

Therefore:

$$\left(1-\frac{2l}{r}\right)\dot{t}=c^{te}=A \tag{12.4.458}$$

Now let us assume that the motion of Mercury is in the equatorial plane such as $\theta=\pi/2$. Hence, the relation obtained above:

$$\frac{\mathrm{d}}{\mathrm{d}s}\left(r^2\sin^2(\theta)\dot{\phi}\right)=0 \tag{12.4.459}$$

simplifies into:

$$\frac{\mathrm{d}}{\mathrm{d}s}(r^2\dot{\theta})=0 \tag{12.4.460}$$

hence:

$$r^2\dot{\phi}=c^{te}=B \tag{12.4.461}$$

We have, therefore, the expression of the Universe line, which, for recall, is:

$$1=\left(1-\frac{2l}{r}\right)c^2\dot{t}^2-\frac{1}{\left(1-\dfrac{2l}{r}\right)}\dot{r}^2-r^2\left(\dot{\theta}^2+\sin^2(\theta)\dot{\phi}^2\right) \tag{12.4.462}$$

Which since $\theta=\pi/2$ (which is therefore a constant) is simplified into:

$$1=\left(1-\frac{2l}{r}\right)c^2\dot{t}^2-\frac{1}{\left(1-\dfrac{2l}{r}\right)}\dot{r}^2-r^2\dot{\phi}^2 \tag{12.4.463}$$

Let us now do the following replacement:

$$r^2\dot{\phi}=B \tag{12.4.464}$$

Which is therefore a constant as we have proved just above and also the following replacement (which is also a constant as we proved just above):

$$\dot{t}=\frac{A}{\left(1-\dfrac{2l}{r}\right)^2} \tag{12.4.465}$$

In the universe line element and we get:

$$1=\left(1-\frac{2l}{r}\right)^{-1}c^2A^2-\left(1-\frac{2l}{r}\right)^{-1}\dot{r}^2-\frac{B^2}{r^2} \tag{12.4.466}$$

Let us consider also r as a function of ϕ then:

$$r' = \frac{\mathrm{d}r}{\mathrm{d}\phi} = \frac{\frac{\mathrm{d}r}{\mathrm{d}s}}{\frac{\mathrm{d}\phi}{\mathrm{d}s}} = \frac{\dot{r}}{\dot{\phi}} \tag{12.4.467}$$

hence:

$$\dot{r} = r'\dot{\phi} = r'\frac{B}{r^2} \tag{12.4.468}$$

Thus, we can rewrite the universe line in the form:

$$\left(1-\frac{2l}{r}\right) = c^2A^2 - r'^2\frac{B^2}{r^4} - \left(1-\frac{2l}{r}\right)\frac{B^2}{r^2} \tag{12.4.469}$$

Let us make a change of variable by putting:

$$r = \frac{1}{u} \Rightarrow \frac{\mathrm{d}r}{\mathrm{d}u} = -\frac{1}{u^2} \Rightarrow \mathrm{d}r = -\frac{\mathrm{d}u}{u^2} \tag{12.4.470}$$

hence:

$$\frac{\mathrm{d}r}{\mathrm{d}\phi} = -\frac{\frac{\mathrm{d}u}{\mathrm{d}\phi}}{u^2} \Rightarrow r' = \frac{u'}{u^2} \tag{12.4.471}$$

Which gives for our universe line:

$$\left(1-2lu\right) = c^2A^2 - u'^2B^2 - \left(1-2lu\right)u^2B^2 \tag{12.4.472}$$

or:

$$\begin{aligned} u'^2 &= \frac{c^2A^2}{B^2} - \frac{\left(1-2lu\right)u^2B^2}{B^2} - \frac{\left(1-2lu\right)}{B^2} \\ &= \frac{c^2A^2}{B^2} - u^2 + 2lu^3 - \frac{1}{B^2} + \frac{2lu}{B^2} \\ &= \frac{c^2A^2-1}{B^2} - u^2 + 2lu^3 + \frac{2lu}{B^2} \end{aligned} \tag{12.4.473}$$

By differentiating:

$$2u'u'' = -2uu' + 6lu^2u' + \frac{2lu'}{B^2} \tag{12.4.474}$$

Or written differently:

$$2u'u'' + 2uu' - 6lu^2u' - \frac{2lu'}{B^2} = 0 \tag{12.4.475}$$

Which simplifies and factorize itself into:

$$u'\left(u'' - \frac{l}{B^2} + u - 3lu^2\right) = 0 \tag{12.4.476}$$

The first possible solution is obviously:

$$u' = 0 \tag{12.4.477}$$

Hence as $r=1/u$:

$$r=c^{te} \tag{12.4.478}$$

The circular motion is thus also a solution of Kepler's problem in General Relativity in a Schwarzschild field (ouf!).

The other solution will be:

$$u''-\frac{l}{B^2}+u-3lu^2=0 \tag{12.4.479}$$

Or written differently:

$$\boxed{u''+u=\frac{l}{B^2}+3lu^2} \tag{12.4.480}$$

it corresponds to the orbit of Kepler's problem.

Let us do the comparison by considering in Newton's mechanics the motion of a particle of mass m in a potential V. The Lagrangian (see section Analytical Mechanics page 3170) is then:

$$L=T-V=\frac{1}{2}mv^2-mf(r) \tag{12.4.481}$$

In polar coordinates we have already seen in different sections (Vector Calculus and Astronomy like at page 5340) that the speed is then written:

$$L=\frac{1}{2}m\left[\left(\frac{\mathrm{d}r}{\mathrm{d}t}\right)^2+r^2\left(\frac{\mathrm{d}\phi}{\mathrm{d}t}\right)^2\right]-mf(r) \tag{12.4.482}$$

Using the Euler-Lagrange equation we have the equation of motion:

$$\frac{\partial L}{\partial r}-\frac{\mathrm{d}}{\mathrm{d}t}\frac{\partial L}{\partial \dot{r}}=0 \tag{12.4.483}$$

Which gives:

$$\frac{\partial L}{\partial r}=rm\left(\frac{\mathrm{d}\phi}{\mathrm{d}t}\right)^2-mf'(r) \quad \text{and} \quad \frac{\mathrm{d}}{\mathrm{d}t}\frac{\partial L}{\partial \dot{r}}=m\frac{\mathrm{d}^2r}{\mathrm{d}t^2} \tag{12.4.484}$$

hence:

$$\frac{\mathrm{d}^2r}{\mathrm{d}t^2}=r\left(\frac{\mathrm{d}\phi}{\mathrm{d}t}\right)^2-f'(r) \tag{12.4.485}$$

And as we have seen in the section Astronomy (see page 5340):

$$r^2\frac{\mathrm{d}\phi}{\mathrm{d}t}=K \tag{12.4.486}$$

Is the constant of areas. Let us introduce:

$$u(\phi)=\frac{1}{r(\phi)} \tag{12.4.487}$$

Hence:

$$u'(\phi)=-\frac{1}{r^2}r'(\phi) \tag{12.4.488}$$

and therefore:

$$\frac{\mathrm{d}r}{\mathrm{d}t}=\frac{\mathrm{d}r}{\mathrm{d}\phi}\frac{\mathrm{d}\phi}{\mathrm{d}t}=r'(\phi)\frac{K}{r^2}=-Ku'(\phi) \tag{12.4.489}$$

So:

$$\begin{aligned}\frac{\mathrm{d}}{\mathrm{d}t}\frac{\mathrm{d}r}{\mathrm{d}t}&=\frac{\mathrm{d}}{\mathrm{d}\phi}\frac{\mathrm{d}\phi}{\mathrm{d}t}\left[-Ku'(\phi)\right]=\frac{\mathrm{d}}{\mathrm{d}\phi}\left[-Ku'(\phi)\right]\frac{\mathrm{d}\phi}{\mathrm{d}t}=-Ku''(\phi)\frac{K}{r^2}\\&=-K^2u''(\phi)u^2\end{aligned} \tag{12.4.490}$$

The equation:

$$\frac{\mathrm{d}^2r}{\mathrm{d}t^2}=r\left(\frac{\mathrm{d}\phi}{\mathrm{d}t}\right)^2-f'(r) \tag{12.4.491}$$

therefore becomes:

$$-K^2u''(\phi)u^2=r\left(\frac{\mathrm{d}\phi}{\mathrm{d}t}\right)^2-f'(r) \tag{12.4.492}$$

But:

$$\frac{\mathrm{d}\phi}{\mathrm{d}t}=\frac{K}{r^2} \tag{12.4.493}$$

Hence:

$$-K^2u''(\phi)u^2=r\left(\frac{K^2}{r^3}\right)^2-f'(r) \tag{12.4.494}$$

therefore:

$$-K^2u''(\phi)u^2=K^2u^3-f'(r) \tag{12.4.495}$$

Where:

$$\boxed{u''(\phi)+u(\phi)=\frac{1}{K^2}\frac{f'(r)}{u^2}} \tag{12.4.496}$$

It is therefore the "non-relativistic Binet formula" which gives the relation between $u=1/r$ and ϕ for a central force (see section Classical Mechanics page 3248). In the case of a Newtonian potential:

$$f(r)=-G\frac{M}{r}\Rightarrow f'(r)=G\frac{M}{r^2}=GMu^2 \tag{12.4.497}$$

Hence:

$$u''(\phi)+u(\phi)=\frac{GM}{K^2} \tag{12.4.498}$$

with for recall:

$$K = r^2 \frac{\mathrm{d}\phi}{\mathrm{d}t} \tag{12.4.499}$$

Now let us recall the form of that which we had obtained just before with the General Relativity:

$$u'' + u = \frac{l}{B^2} + 3lu^2 \tag{12.4.500}$$

Thus, we see that the analogous term in relativity is:

$$\frac{l}{B^2} = \frac{\dfrac{GM}{c^2}}{B^2} \tag{12.4.501}$$

and that General Relativity adds the term $3lu^2$. Now, as in General Relativity:

$$B = r^2 \dot{\phi} \tag{12.4.502}$$

Then:

$$\frac{l}{B^2} = \frac{\dfrac{GM}{c^2}}{r^4 \left(\dfrac{\mathrm{d}\phi}{\mathrm{d}s}\right)^2} = \frac{GM}{c^2 r^4 \left(\dfrac{\mathrm{d}\phi}{\mathrm{d}s}\right)^2 \left(\dfrac{\mathrm{d}t}{\mathrm{d}s}\right)^2} \tag{12.4.503}$$

However, in the case of the approximation of weak fields:

$$\mathrm{d}s^2 = c^2 \mathrm{d}t^2 - \left(\mathrm{d}x_1^2 + \mathrm{d}x_2^2 + \mathrm{d}x_3^2\right) \tag{12.4.504}$$

Hence:

$$\frac{\mathrm{d}s^2}{\mathrm{d}t^2} = c^2 \left[1 - \beta^2\right] \underset{v \ll c}{\cong} c^2 \tag{12.4.505}$$

So finally:

$$\frac{l}{B^2} = \frac{GM}{c^2 r^4 \left(\dfrac{\mathrm{d}\phi}{\mathrm{d}s}\right)^2 \left(\dfrac{\mathrm{d}t}{\mathrm{d}s}\right)^2} \cong \frac{GM}{r^4 \left(\dfrac{\mathrm{d}\phi}{\mathrm{d}s}\right)^2} = \frac{GM}{K^2} \tag{12.4.506}$$

That said, it is really interesting to note that the equation for General Relativity:

$$u'' + u = \frac{l}{B^2} + 3lu^2 \tag{12.4.507}$$

can be interpreted as Binet's equation for Classical Mechanics:

$$u'' + u = \frac{1}{K^2} \frac{f'(r)}{u^2} \tag{12.4.508}$$

with the potential:

$$f(r) = -\frac{GM}{r} - \frac{\gamma}{r^3} \tag{12.4.509}$$

with $\gamma = lK^2$.

Let us now return to our equation:

$$u'' + u = \frac{l}{B^2} + 3lu^2 \tag{12.4.510}$$

We would like to know if the second term on the right of the equality is negligible or not with respect to the first term on the right of the equality in order to be able to apply the theory of perturbations.

We will first put with the help of the weak field approximation given above:

$$C = \frac{l}{B^2} \cong \frac{GM}{K^2} \tag{12.4.511}$$

Now let us calculate the ratio:

$$\begin{aligned}\frac{3lu^2}{\dfrac{l}{B^2}} &= 3B^2u^2 = 3\left(r^2\dot{\phi}\right)^2\frac{1}{r^2} = 3r^2\dot{\phi}^2 = 3\left(r^2\left(\frac{\mathrm{d}\phi}{\mathrm{d}s}\right)^2\right)\\ &= 3\left(r^2\left(\frac{\mathrm{d}\phi}{\mathrm{d}t}\right)^2\left(\frac{\mathrm{d}t}{\mathrm{d}s}\right)^2\right) \cong 3\left(r\frac{\mathrm{d}\phi}{\mathrm{d}t}\right)^2\frac{1}{c^2}\end{aligned} \tag{12.4.512}$$

Recall that in polar coordinates (see section Vector Calculus page 1863):

$$v^2 = \left(\frac{\mathrm{d}r}{\mathrm{d}t}\right)^2 + r^2\left(\frac{\mathrm{d}\phi}{\mathrm{d}t}\right)^2 \tag{12.4.513}$$

In approximation, we can roughly put that:

$$v^2 \cong r^2\left(\frac{\mathrm{d}\phi}{\mathrm{d}t}\right)^2 \tag{12.4.514}$$

Therefore for Mercury ...:

$$\frac{3lu^2}{\dfrac{l}{B^2}} \cong 3\frac{\nu^2}{c^2} \cong 7.7\cdot 10^{-8} \tag{12.4.515}$$

So we see immediately that we can apply the variational theories to the term $3lu^2$. Thus, let us put:

$$\varepsilon = 3lC = 3l\frac{l}{B^2} \cong 3\frac{GM}{c^2}\frac{GM}{K^2} = 3\frac{G^2M^2}{c^2K^2} \tag{12.4.516}$$

The equation:

$$u'' + u = \frac{l}{B^2} + 3lu^2 \tag{12.4.517}$$

takes the shape:

$$u'' + u = C + \frac{\varepsilon}{C}u^2 \tag{12.4.518}$$

To solve this differential equation, we will use the perturbation theory approach (see section Differential and Integral Calculus page 1645). We will therefore focus on a solution of the form of a Taylor expansion in second order only in ε:

$$u=u_0+\varepsilon u_1+\mathcal{O}(\varepsilon^2) \tag{12.4.519}$$

where u_0, u_1 are obviously dependent on ϕ and will have to be determined! To do this, we know that we must replace the previous expression in the differential equation such that:

$$\left(u_0+\varepsilon u_1+\mathcal{O}(\varepsilon^2)\right)''+\left(u_0+\varepsilon u_1+\mathcal{O}(\varepsilon^2)\right)=C+\frac{\varepsilon}{C}\left(u_0+\varepsilon u_1+\mathcal{O}(\varepsilon^2)\right)^2 \tag{12.4.520}$$

Which simplifies into:

$$u_0''+\varepsilon u_1''+u_0+\varepsilon u_1=C+\frac{\varepsilon u_0^2}{C}+\mathcal{O}(\varepsilon^2) \tag{12.4.521}$$

where let us recall that:

$$u_0''+u_0=C \tag{12.4.522}$$

is the classical equation obtained earlier above:

$$u_0''+u=\frac{GM}{K^2} \tag{12.4.523}$$

Let us consider the solution of the type:

$$u_0=C+D\cos(\phi) \tag{12.4.524}$$

where D is an arbitrary constant. Now, as we have seen in the section of Astronomy in the case of the precession of perihelion:

$$\frac{1}{r}=\frac{B}{\Omega^2}+k_1\cos(\Omega\theta) \tag{12.4.525}$$

is actually an ellipse. Which means that any solution of the form:

$$u_0=C+D\cos(\phi) \tag{12.4.526}$$

is also an ellipse!

For the equation in ε:

$$\varepsilon u_1''+\varepsilon u_1=\frac{\varepsilon u_0^2}{C} \tag{12.4.527}$$

which is simplified into:

$$u_1''+u_1=\frac{(C+D\cos(\phi))^2}{C}=C+2D\cos(\phi)+\frac{D^2}{C}\cos^2(\phi) \tag{12.4.528}$$

Since (see section Trigonometry page 2519):

$$\cos^2(\phi)=\frac{\cos(2\phi)+1}{2} \tag{12.4.529}$$

It comes:

$$\begin{aligned} u_1''+u_1&=\frac{(C+D\cos(\phi))^2}{C}=C+2D\cos(\phi)+\frac{D^2}{C}\frac{\cos(2\phi)+1}{2}\\ &=\left(C+\frac{D^2}{2C}\right)+2D\cos(\phi)+\frac{D^2}{2C}\cos(2\phi)\end{aligned}\tag{12.4.530}$$

To determine u_1, let us decompose it into three terms:

$$u_1=X_1+X_2+X_3\tag{12.4.531}$$

This gives us immediately (by injecting the three terms respectively into the second derivative and the term alone):

$$\begin{aligned} &X_1''+X_1=C+\frac{D^2}{2C}\Rightarrow X_1=C+\frac{D^2}{2C}\\ &X_2''+X_2=2D\cos(\phi)\Rightarrow X_2=D\phi\sin(\phi)\\ &X_3''+X_3=\frac{D^2}{2C}\cos(2\phi)\Rightarrow X_3=-\frac{D^2}{6C}\cos(2\phi)\end{aligned}\tag{12.4.532}$$

So finally:

$$u_1=C+\frac{D^2}{2C}+D\phi\sin(\phi)-\frac{D^2}{6C}\cos(2\phi)\tag{12.4.533}$$

The solution sought is finally:

$$\begin{aligned} u&=u_0+\varepsilon u_1+\mathcal{O}(\varepsilon^2)=(C+D\cos(\phi))+\varepsilon\left(C+\frac{D^2}{2C}+D\phi\sin(\phi)-\frac{D^2}{6C}\cos(2\phi)\right)\\ &=\left(C+\varepsilon C+\frac{\varepsilon D^2}{2C}\right)+\left(D\cos(\phi)-\varepsilon\frac{D^2}{6C}\cos(2\phi)\right)+\varepsilon D\phi(\sin\phi)\end{aligned}\tag{12.4.534}$$

It is therefore with:

$$u(\phi)=\left(C+\varepsilon C+\frac{\varepsilon D^2}{2C}\right)+\left(D\cos(\phi)-\varepsilon\frac{D^2}{6C}\cos(2\phi)\right)+\varepsilon D\phi\sin(\phi)\tag{12.4.535}$$

that it is necessary to calculate the displacement of the perihelion (we arrive soon... pfiuuuuu...).

$$\cos(\phi-\varepsilon\phi)=\cos(\phi)\cos(\varepsilon\phi)+\sin(\phi)\sin(\varepsilon\phi)\tag{12.4.536}$$

We see relatively quickly by observing the preceding relation that the only term whose amplitude is not constant is $\varepsilon D\phi\sin(\phi)$.

Let us then recall that (see section Trigonometry page 2519):

$$\cos(\phi-\varepsilon\phi)\cong\cos(\phi)+\phi\sin(\varepsilon\phi)\tag{12.4.537}$$

This can also be roughly written as a first approximation using Maclaurin's first-order expansion (see section Sequences and Series page 1703):

$$\begin{aligned} u(\phi)&=\left(C+\varepsilon C+\frac{\varepsilon D^2}{2C}\right)+\left(D\cos(\phi)-\varepsilon\frac{D^2}{6C}\cos(2\phi)\right)+\varepsilon D\phi\sin(\phi)\\ &\cong\left(C+\varepsilon C+\frac{\varepsilon D^2}{2C}\right)+\left(-\varepsilon\frac{D^2}{6C}\cos(2\phi)\right)+D\cos(\phi-\varepsilon\phi)\\ &=C+D\cos(\phi-\varepsilon\phi)+\varepsilon\left(C+\frac{D^2}{2C}-\frac{D^2}{6C}\cos(2\phi)\right)\end{aligned}\tag{12.4.538}$$

We know that the zero order orbit is:

$$u_0 = C + D\cos(\phi) \qquad (12.4.539)$$

The effect of the last term:

$$\varepsilon\left(C + \frac{D^2}{2C} - \frac{D^2}{6C}\cos(2\phi)\right) \qquad (12.4.540)$$

is therefore to introduce a small periodic variation in the radial distance. This term does not affect the displacement of the perihelion. This is the term $\varepsilon\phi$ in:

$$\cos(\phi - \varepsilon\phi) = \cos(\phi(1-\varepsilon)) \qquad (12.4.541)$$

which introduces a non-periodicity which can be non-negligible in the case where ϕ is large.

The perihelion (the point closest to the Sun for recall) therefore appears when r is the minimum therefore $u = 1/r$ maximum. But, u is maximum when the term which interests us is maximum, that is to say:

$$\phi(1-\varepsilon) = 2\pi n \qquad n \in \mathbb{Z} \qquad (12.4.542)$$

We have approximately:

$$\phi = \frac{2\pi n}{1-\varepsilon} \cong 2\pi n(1+\varepsilon) \qquad (12.4.543)$$

For two successive perihelions, we have an interval:

$$\Delta\phi \cong 2\pi(1+\varepsilon) = 2\pi + 2\pi\varepsilon = 2\pi + \delta\phi \qquad (12.4.544)$$

instead of 2π. Thus, the displacement for a revolution is:

$$\delta\phi \cong 2\pi\varepsilon = 2\pi\left(3\frac{G^2M^2}{c^2K^2}\right) = \frac{6\pi G^2M^2}{c^2K^2} = \frac{6\pi G^2M^2}{c^2\left(r^2\dfrac{\mathrm{d}\phi}{\mathrm{d}t}\right)^2} = \frac{6\pi G^2M^2}{c^2r^2\nu^2} \qquad (12.4.545)$$

where K is therefore the constant of the areas and M the mass of the central star and since:

$$v = \omega \cdot r = \frac{\mathrm{d}\phi}{\mathrm{d}t} \cdot r \qquad (12.4.546)$$

Finally we have in the end the "Schwarzschild precession":

$$\boxed{\Delta\phi \cong \frac{6\pi G^2M^2}{c^2v^2r^2}} \qquad (12.4.547)$$

Relation to be compared with that obtained in the section of Astronomy with a Classical Newtonian treatment (see page 5361):

$$\Delta\alpha = \frac{\pi G^2M^2}{c^2v^2r^2} \qquad (12.4.548)$$

We thus fall back at the perfection on the factor 6 which was lacking in the conventional treatments!

For Mercury a numerical application gives:

$$\delta\phi \cong \frac{6\pi G^2M^2}{c^2r^2v^2} \cong 42.89'' \qquad (12.4.549)$$

and the experiment gives $\delta\phi \cong 42.5'' \pm 1.0''$. By Albert Einstein's own admission, in obtaining this result he had palpitations and the impression of grazing a heart attack and satisfied with his Herculean effort which had exhausted him he took a long period of rest.

Remark

It is perhaps useful for the reader to know that Albert Einstein and Michele Besso took almost 2 years (!!!) by trials and errors to find the good result above. The first time they had an error of 4000% in comparison to the experimental observed value, the second time an error of 400% and finally the value above (after that Albert Einstein had identified that he choose the wrong Tensor for his theory).

The figure generated by such a precession is commonly named a "rosette". For example here is an artistic illustration of the rosette generated by the orbit of a star around a punctual Black Hole:

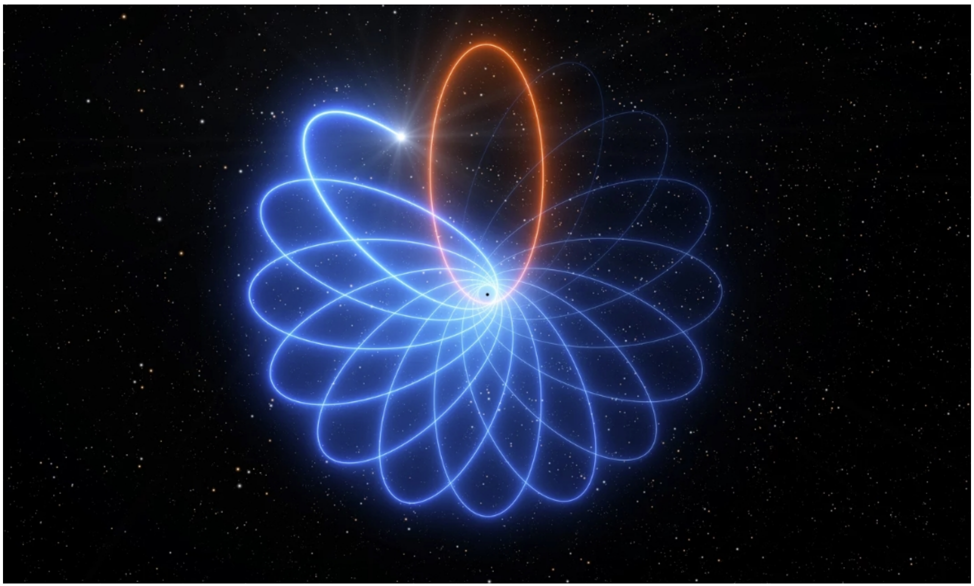

Figure 12.225: **Artistic representation of a Schwarzschild precession with visible rosette (credit: Luis Calcada, Creative Commons Attribution 4.0 International License)**

To conclude on this subject, let us mention a second frequent writing in the literature concerning the result obtained. Indeed, we have proved in the section of Astronomy that the focal parameter was given by:

$$p=\frac{\|\vec{v}\times\vec{r}\|^2}{GM}=\frac{v^2\cdot r^2}{GM} \tag{12.4.550}$$

It therefore remains:

$$\Delta\alpha\cong\frac{6\pi GM}{c^2p} \tag{12.4.551}$$

and we have also proved in the section of Analytical Geometry (see page 2787) that:

$$p=a\left(1-e^2\right) \tag{12.4.552}$$

It thus comes in the end the most classic form:

$$\boxed{\Delta\alpha\cong\frac{6\pi GM}{c^2a\left(1-e^2\right)}} \tag{12.4.553}$$

the numerical values for Mercury precession with $G=6.674\cdot 10^{-11}$ [$\text{m}^3\cdot\text{kg}^{-1}\cdot\text{s}^{-2}$], $M=1.99\cdot 10^{30}$ [kg], $e=0.260$, $a=5.787\cdot 10^{10}$ [m] and $T=88$ [days], gives for a century (100 years of 365 days):

$$\Delta\alpha\frac{100\cdot 365}{88}=\frac{\pi GM}{a(1-e^2)c^2}\frac{100\cdot 365}{88}\cong 5.0267\cdot 10^{-7}\cdot 414.772\cong 2.08\cdot 10^{-4}\,[\text{rad}\cdot\text{century}^{-1}] \quad (12.4.554)$$

Thus a precession of an angle of $43,00415''$. This is a reaaaaallllly good result!

Now there is a curious exercise to be play here with the relation of $\Delta\alpha$, let's compute the relativistic size of the perihelion for various astrophysics systems.

System	**Central Mass**	***a***	***e***	P_{orb}	$\Delta\alpha$
Mercury-Sun	$1\,M_\odot$	$5.70\cdot 10^{10}$ [m]	0.2056	87.969 days	$0.4299''$ /yr
PSR J0737-3039	$1.35+1.24\,M_\odot$	$8.66\cdot 10^{8}$ [m]	0.09	2.4 hours	$17.6°$ /yr
Earth-Moon	$1.35+1.24\,M_\oplus$	$3.84\cdot 10^{8}$ [m]	0.0549	27.32 days	$0.00027''$ /yr
Jupiter-Io	$1.899\cdot 10^{27}$ [kg]	$4.33\cdot 10^{8}$ [m]	0.0041	1.769 days	$2.68''$ /yr
Jupiter-Europa	$1.899\cdot 10^{27}$ [kg]	$6.71\cdot 10^{8}$ [m]	0.094	3.551 days	$0.84''$ /yr
Jupiter-Amalthea	$1.899\cdot 10^{27}$ [kg]	$1.81\cdot 10^{8}$ [m]	0.0032	43.043 [s]	$22.15''$ /yr

12.4.6.3 Deflection of Light (light bending)

We have just proved that:

$$u''+u=\frac{l}{B^2}+3lu^2 \quad (12.4.555)$$

By replacing the factors by their respective values, we have:

$$u''+u=\frac{GM}{c^2B^2}+3\frac{GM}{c^2}u^2 \quad (12.4.556)$$

But we have seen above that:

$$B^2=\frac{lK^2}{GM} \quad (12.4.557)$$

and as K is the areas constant given by the conservation of the momentum itself constant (see section Classical Mechanics page 3244):

$$b=mr^2\omega=mr^2\frac{\mathrm{d}\phi}{\mathrm{d}t}=mK\Rightarrow K=\frac{b}{m} \quad (12.4.558)$$

We then have for a photon $m\rightarrow 0\Rightarrow K\rightarrow +\infty$.

Finally the equation of motion for a photo becomes:

$$u''+u=3\frac{GM}{c^2}u^2 \quad (12.4.559)$$

Let us put now to simplify the notations:

$$r_g=\frac{2GM}{c^2} \tag{12.4.560}$$

Then:

$$u''+u=\frac{3}{2}r_g u^2 \tag{12.4.561}$$

The term to the right of the equality is small (considering the constants that intervene therein) so that an approximate form of the differential equation is:

$$u''+u=0 \tag{12.4.562}$$

of which a particular solution, which we know in advance, is interesting:

$$u=u_0\cos(\varphi) \tag{12.4.563}$$

We carry this approximated solution in the initial differential equation and we get:

$$u''+u=\frac{3}{2}r_g u_0^2\cos^2(\varphi) \tag{12.4.564}$$

Therefore:

$$u''+u=\frac{3}{2}r_g u_0^2\left(\frac{1}{2}+\frac{1}{2}\cos(2\varphi)\right)=\frac{3}{4}r_g u_0^2+\frac{3}{4}r_g u_0^2\cos(2\varphi) \tag{12.4.565}$$

Hence:

$$\frac{\partial^2 u}{\partial\phi^2}+u=\frac{3}{4}r_g u_0^2+\frac{3}{4}r_g u_0^2\cos(2\varphi) \tag{12.4.566}$$

What follows is going to be very subtle (how to guess something like that ...?). First we will create a new differential equation:

$$\frac{\partial^2 v}{\partial\phi^2}+v=\frac{3}{4}r_g u_0^2+\frac{3}{4}r_g u_0^2\sin(2\varphi) \tag{12.4.567}$$

The trick is to multiply this equation by i and sum it to the original differential equation:

$$\frac{\partial^2}{\partial\phi^2}(u+\mathrm{i}v)+(u+\mathrm{i}v)=\frac{3}{4}r_g u_0^2(1+\mathrm{i})+\frac{3}{4}r_g u_0^2 e^{\mathrm{i}2\varphi} \tag{12.4.568}$$

What we will denote by:

$$\frac{\partial^2\bar{u}}{\partial\phi^2}+\bar{u}=\frac{3}{4}r_g u_0^2\sqrt{2}e^{\mathrm{i}\frac{\pi}{4}}+\frac{3}{4}r_g u_0^2 e^{\mathrm{i}2\varphi} \tag{12.4.569}$$

Another trick is to look for a particular solution of the previous relation in the form:

$$\bar{u}=A+Be^{\mathrm{i}2\varphi} \tag{12.4.570}$$

Then we have:

$$\begin{aligned}\bar{u}'&=2\mathrm{i}Be^{\mathrm{i}2\varphi}\\ \bar{u}''&=-4Be^{\mathrm{i}2\varphi}\end{aligned} \tag{12.4.571}$$

This injected into our new differential equation gives:

$$-4Be^{\mathrm{i}2\varphi}+A+Be^{\mathrm{i}2\varphi}=\frac{3}{4}r_gu_0^2\sqrt{2}e^{\mathrm{i}\frac{\pi}{4}}+\frac{3}{4}r_gu_0^2e^{\mathrm{i}2\varphi} \qquad (12.4.572)$$

We deduce immediately:

$$\begin{aligned}A&=\frac{3}{4}r_gu_0^2\sqrt{2}e^{\mathrm{i}\frac{\pi}{4}}\\B&=-\frac{1}{4}r_gu_0^2\end{aligned} \qquad (12.4.573)$$

A particular solution of the original differential equation is thus:

$$\begin{aligned}&u=\Re(\bar{u})=\Re\left(\frac{3}{4}r_gu_0^2\sqrt{2}e^{\mathrm{i}\frac{\pi}{4}}-\frac{1}{4}r_gu_0^2e^{\mathrm{i}2\varphi}\right)=\frac{3}{4}r_gu_0^2-\frac{1}{4}r_gu_0^2\cos(2\varphi)\\&=\frac{1}{2}r_gu_0^2\left(\frac{3}{2}-\frac{1}{2}\cos(2\varphi)\right)\end{aligned} \qquad (12.4.574)$$

Either by using the remarkable trigonometric relations (see section Trigonometry page 2519):

$$\cos(2\varphi)=1-2\sin^2(\varphi) \qquad (12.4.575)$$

It comes:

$$u=\frac{1}{2}r_gu_0^2\left(\frac{3}{2}-\frac{1}{2}+\sin^2(\varphi)\right)=\frac{1}{2}r_gu_0^2\left(1-\sin^2(\varphi)\right) \qquad (12.4.576)$$

The general solution is:

$$u=u_0\cos(\varphi)+\frac{1}{2}r_gu_0^2\left(1-\sin^2(\varphi)\right) \qquad (12.4.577)$$

If we admit that the light is very weakly deviated by the Sun, the radius of curvature ($1/r$) of its trajectory will be very small.

Therefore:

$$u=\frac{1}{r}\rightarrow 0 \qquad (12.4.578)$$

such that:

$$u_0\cos(\varphi)+\frac{1}{2}r_gu_0^2\left(1-\sin^2(\varphi)\right)\cong 0 \qquad (12.4.579)$$

The first term is predominant relatively to the second because of the factor r_g that is very small on the second. For what will follow, we will proceed as in the in the section Astronomy (only the notations change) for the study of the deflection angle at page 5358 (if you don't come back to it, it may be difficult to understand the justification of what will follow!). We put without loosing in generality:

$$\theta=2\varphi-\pi \qquad (12.4.580)$$

Therefore:

$$\varphi=\frac{\pi}{2}+\frac{\theta}{2} \qquad (12.4.581)$$

and as:

$$\begin{aligned}\cos(\varphi)&=\cos\left(\frac{\pi}{2}+\frac{\theta}{2}\right)=-\sin\left(\frac{\theta}{2}\right)\\ \sin^2(\varphi)&=\sin^2\left(\frac{\pi}{2}+\frac{\theta}{2}\right)=\cos^2\left(\frac{\theta}{2}\right)\end{aligned}\tag{12.4.582}$$

it comes:

$$-u_0\sin\left(\frac{\theta}{2}\right)+\frac{1}{2}r_gu_0^2\left(1+\cos^2\left(\frac{\theta}{2}\right)\right)\cong 0\tag{12.4.583}$$

Using trigonometric identities again:

$$\cos^2\left(\frac{\theta}{2}\right)=\frac{1+\cos^2\left(2\dfrac{\theta}{2}\right)}{2}\tag{12.4.584}$$

It comes:

$$-\sin\left(\frac{\theta}{2}\right)+\frac{1}{2}r_gu_0\left(\frac{3}{2}+\frac{1}{2}\cos(\theta)\right)\cong 0\tag{12.4.585}$$

θ being supposed as very small we do a Maclaurin development (see section Sequences and Series page 1703) to the first order of the trigonometric functions:

$$-\frac{\theta}{2}+\frac{1}{2}r_gu_0\left(\frac{3}{2}+\frac{1}{2}\right)\cong 0\tag{12.4.586}$$

Which gives:

$$-\frac{\theta}{2}+r_gu_0\cong 0\Rightarrow\theta\cong 2r_gu_0=\frac{4GM}{c^2}\frac{1}{r_0}\tag{12.4.587}$$

Therefore after a series of approximation... and of hypothesis at the limit of what is acceptable..., we then get for the "deflection of light[49]" (R is sometimes named the "impact parameter", that is to say the distance of nearest approach of the light-beam to the center of mass):

$$\boxed{\theta\cong\frac{4GM}{c^2R}}\tag{12.4.588}$$

instead of the result that we get following the Newtonian approach in the section Astronomy (see page 5358):

$$\varphi\cong\frac{2GM}{v^2r}\tag{12.4.589}$$

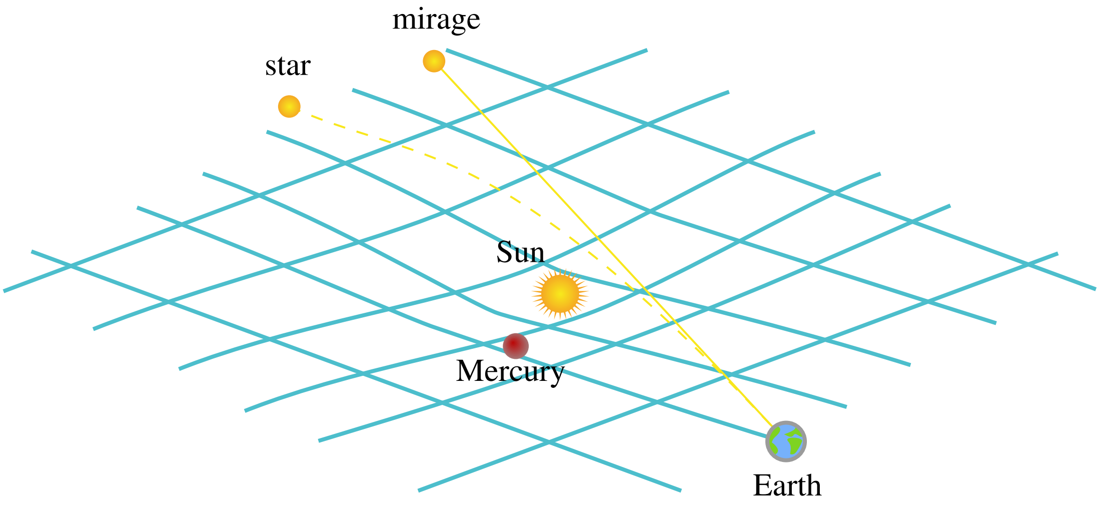
We thus found the factor 2 that was missing in the classical treatment, relatively to experimental observations, that we have proved in the section of Astronomy (see page 5358):

$$\delta_{\text{relativistic}}=2\cdot\delta_{\text{newtonian}}=1.74''\tag{12.4.590}$$

What is often pictured in the media by the following drawing:

---

[49] Also sometimes named "depiction of light".



This deviation have been observed experimentally by measuring the position of stars in the vicinity of the solar disk during the 11919 (holocene calendar) eclipse by Arthur Eddington and his team (see [161]). After the advance of the perihelion of Mercury, this was the second test successfully passed by the General Relativity. It was this event that made Albert Einstein famous among the general public. Today, the deviation of light rays can be measured with much greater precision by considering radio signals emitted by extra-galactic sources (quasars, AGN, etc.): the prediction of the General Relativity has been confirmed to the nearest thousandth.

The deviation of light rays is today very important in observational cosmology. Since it is at the origin of the phenomenon of gravitational mirage, also named "gravitational lens".

It is interesting to notice that the whole theory of gravitational mirages is based on the relation:

$$\theta \cong \frac{4GM}{c^2R} \tag{12.4.591}$$

at least for a point detector. It is the only ingredient of General Relativity used in the calculation of images.

Here is a Flash animation of what a light bulb light rays propagation in vacuum, ON, would looks like (objects are obviously not to scale...):

The animation above will run for people having a PDF reader with Adobe Flash player installed and activated (otherwise see here: https://vimeo.com/575751871).

And here is also for recall a Flash animation of what a light bulb light rays propagation in vacuum putted in the presence of a punctual mass, ON, would looks like:

The animation above will run for people having a PDF reader with Adobe Flash player installed and activated (otherwise see here: https://vimeo.com/575750678).

And here is a Flash animation of what a light bulb light rays propagation in vacuum putted in the presence of a punctual mass but taking into account General Relativity, ON, would looks like (we can see in gray the Schwarzschild radius of the punctual mass):

The animation above will run for people having a PDF reader with Adobe Flash player installed and activated (otherwise see here: https://vimeo.com/575751098).

And here is a Flash of what a light bulb light rays propagation in vacuum putted in the presence of a rotating mass but taking into account General Relativity, ON, would looks like (we can see in dark gray the Schwarzschild radius and in light gray the ergosphere radius of the rotating mass):

The animation above will run for people having a PDF reader with Adobe Flash player installed and activated (otherwise see here: https://vimeo.com/575750255).

In observational astronomy an "Einstein ring", also known as an "Einstein-Chwolson ring" or "Chwolson ring", is the deformation of the light from a source (such as a galaxy or star) into a ring through gravitational lensing of the source's light by an object with an extremely large mass (such as another galaxy or a Black Hole). This occurs when the source, lens, and observer are all aligned.

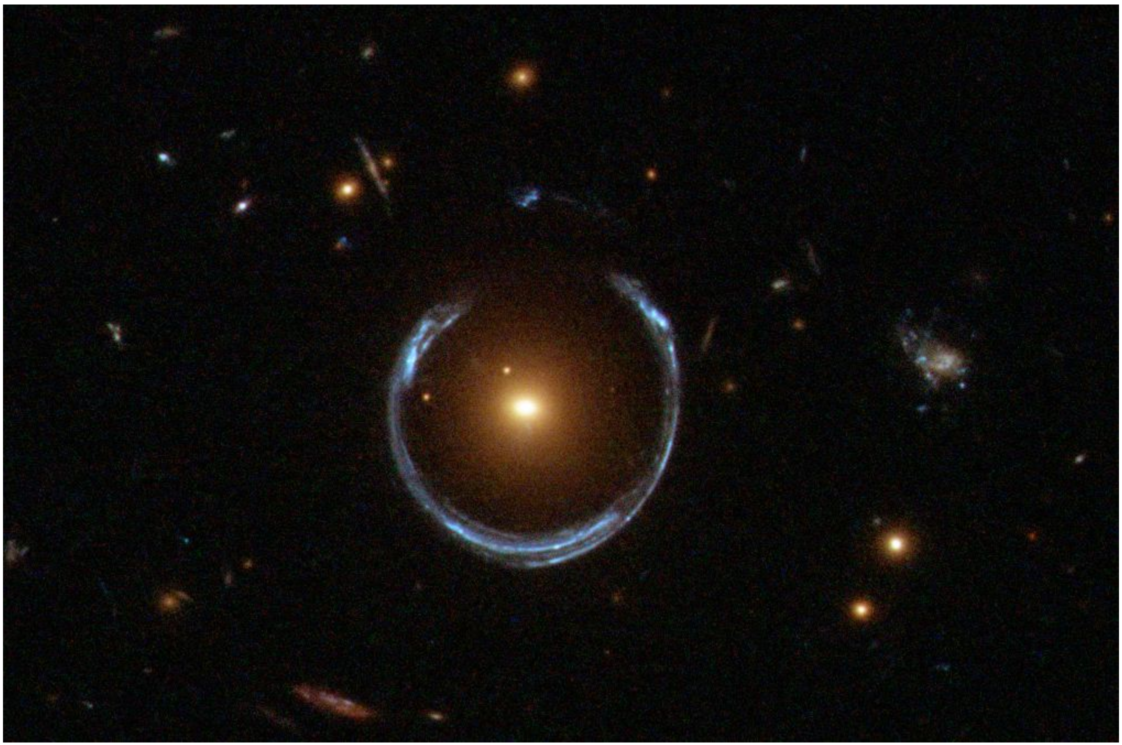


Figure 12.226: Einstein Ring LRG 3 757

When it comes to the distant universe, even the keen vision of NASA's Hubble Space Telescope can only go so far. Teasing out finer details requires clever thinking and a little help from a cosmic alignment with a gravitational lens.

By applying a new computational analysis to a galaxy magnified by a gravitational lens, astronomers have obtained images ten times sharper than what Hubble could achieve on its own. The results show an edge-on disk galaxy studded with brilliant patches of newly formed stars.

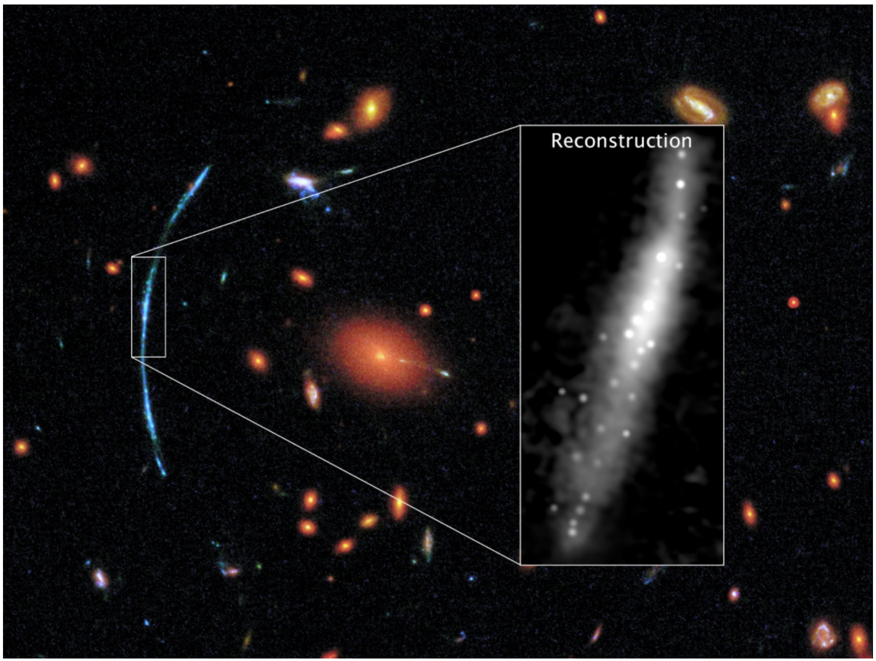

Figure 12.227: **SGAS J111020.0+645950.8 arc magnified by the galaxy cluster SDSS J1110+6459 (source: NASA, ESA, and T. Johnson (University of Michigan))**

In the above Hubble photograph of a distant galaxy cluster, a spotty blue arc stands out against a background of red galaxies. That arc is actually three separate images of the same background galaxy. The background galaxy has been gravitationally lensed, its light magnified and distorted by the intervening galaxy cluster. On the right: How the galaxy would look to Hubble without distortions.

« *When we saw the reconstructed image we said, 'Wow, it looks like fireworks are going off everywhere* », said astronomer Jane Rigby of NASA's Goddard Space Flight Center in Greenbelt, Maryland.

The galaxy in question is so far away that we see it as it appeared 11 billion years ago, only 2.8 billion years after the Big Bang (i.e. starting point of the expansion of our universe). It is one of more than 70 strongly lensed galaxies studied by the Hubble Space Telescope, following up targets selected by the Sloan Giant Arcs Survey, which discovered hundreds of strongly lensed galaxies by searching Sloan Digital Sky Survey imaging data covering one-fourth of the sky.

The gravity of a giant cluster of galaxies between the target galaxy and Earth distorts the more distant galaxy's light, stretching it into an arc and also magnifying it almost 30 times. The team had to develop special computer code to remove the distortions caused by the gravitational lens, and reveal the disk galaxy as it would normally appear.

The resulting reconstructed image revealed two dozen clumps of newborn stars, each spanning about 200 to 300 light-years. This contradicted theories suggesting that star-forming regions in the distant, early universe were much larger, $3,000$ light-years or more in size.

So we have proved above that light is bent near a mass. So this is obviously interpreted as an effect on gravity on light. But the reader must remember something important... the light isn't accelerated because light travels always at the speed of light as it is mass-less (special theory of relativity) instead it is "kind of" accelerated: light is blueshifted if shot directly into a massive body. Since light speed is fixed, it gains energy by increasing its frequency (or shortening its wavelenght).

12.4.6.4 Shapiro Effect (delay)

In 11964 (holocene calendar), Irwin Shapiro demonstrated that a ray of light was not only deflected by passing near a mass, but also that the duration of its path was lengthened in relation to a Euclidean geometry. He calculated that the delay should be about 200 microseconds, therefore perfectly measurable, for a line of sight shaving the Sun. He then suggested systematically measuring the time taken by a radar signal to make the round trip between the Earth and a planet passing behind the Sun (so that the effect is maximal). This was first accomplished with radar echoes on Mars, Venus or Mercury, with an accuracy of the order of 20%. The result was very clear: the time required for a radar signal to make the go and come back between the Earth and the other Planet increases suddenly just before the planet passes behind the Sun and decreases just as suddenly when it reappears.

Remark

We sometimes also talk of "slowing down of the light" near the Sun (actually a G2V-type star, aka yellow dwarf) to describe the Shapiro effect, but it is an awkward and erroneous expression. As we have already been mention it, the speed of light is constant in General Relativity as well as in Relativity for all observers (but for recall this doesn't mean that the speed of light in constant during the life of our Universe!). In the case of the Shapiro effect (and in other similar cases), what changes is the flow of time where the light passes, in relation to what it is where the observer is located.

Although this is a weak effect, it has been verified precisely since the arrival of the Viking probes on Mars in 11976 (holocene calendar), using signals sent from Earth to Mars and reflecting on the latter by the probes (see the principle of the experiment in the figure further below). In addition, there is now even an increasingly common object for which the Shapiro effect must be taken into account: the "G.P.S." (Global Positioning System). Indeed, despite the weakness of the field of gravitation, a geographical precision of a few meters requires such details in the calculation! However, a couple of satellites (LASER-ranged satellites: LAGEOS and LAGEOS II) have been launched to verify in the Earth's gravitational field an even lower effect predicted by General Relativity and which does not even intervene in GPS: the drag over of space also known as the "Lense-Thirring effect" due to the rotation of Earth. These satellites, and the associated scientific teams, did confirmed with 99% accuracy the result of General Relativity in 12004 (holocene calendar)!

Let us point out for the GPS that two source of errors are known within the framework of the Relativity:

1. The satellites rotating around the Earth at a speed of approximately $14,000$ kilometres per hour then delay 7 millionths of a second per day (relativity).
2. At an altitude of $20,200$ kilometres, that of the satellite orbit, the lower gravitational field advances the satellite clocks by 45 millionths of a second per day.

The sum of the two corrections gives a drift of 38 millionths of a second per day, a staggering figure for a GPS system whose precision must be 50 billionths of a second per day!!!

Let us make the calculation for a ray touching the surface of the Sun. For this, we take up our Schwarzschild's metric given for recall by:

$$\mathrm{d}s^2=\left(1-\frac{r_g}{r}\right)c^2\mathrm{d}t^2-\frac{1}{\left(1-\dfrac{r_g}{r}\right)}\mathrm{d}r^2-r^2\left(\mathrm{d}\theta^2+\sin^2(\theta)\mathrm{d}\phi^2\right)\qquad(12.4.592)$$

with:

$$r_g=\frac{2GM}{c^2}\qquad(12.4.593)$$

For a photon, we know that $\mathrm{d}s=0$ and therefore the equation of the Schwarzschild's metric is then written:

$$c^2\mathrm{d}t^2=\frac{1}{\left(1-\dfrac{r_g}{r}\right)^2}\mathrm{d}r^2+\frac{r^2(\mathrm{d}\theta^2+\sin^2(\theta)\mathrm{d}\phi^2)}{\left(1-\dfrac{r_g}{r}\right)}\qquad(12.4.594)$$

The trajectory of the photon taking place in the equatorial plane of the Sun, we put:

$$\theta=c^{te}=\frac{\pi}{2}\qquad(12.4.595)$$

which simplifies even more the equation of the metric into:

$$c^2\mathrm{d}t^2=\frac{1}{\left(1-\dfrac{r_g}{r}\right)^2}\mathrm{d}r^2+\frac{r^2\mathrm{d}\phi^2}{\left(1-\dfrac{r_g}{r}\right)}=\frac{1}{\left(1-\dfrac{r_g}{r}\right)^2}\left(\mathrm{d}r^2+\left(1-\frac{r_g}{r}\right)r^2\mathrm{d}\phi^2\right)\qquad(12.4.596)$$

To simplify even more, we make the hypothesis that the trajectory (in polar coordinates) of the photon shaving the Sun is rectilinear such that (for one of the polar components of the plane):

$$r\cos(\phi)=r_\odot\qquad(12.4.597)$$

where $r_\odot$ is the ray of the Sun. We will use this assumption to simplify the equation of the metric. For this we rearrange:

$$r=\frac{r_\odot}{\cos(\phi)}\qquad(12.4.598)$$

We derive (see section Differential and Integral Calculus page 1475):

$$\frac{\mathrm{d}r}{\mathrm{d}\phi}=\frac{r_\odot\sin(\phi)}{\cos^2(\phi)}=\frac{r_\odot\sin(\phi)}{\dfrac{r_\odot}{r^2}}=\frac{r^2\sin(\phi)}{r_\odot}\qquad(12.4.599)$$

If we square everything:

$$\left(\frac{\mathrm{d}r}{\mathrm{d}\phi}\right)^2=\frac{r^4\sin^2(\phi)}{r_\odot^2}=\frac{r^4(1-\cos^2(\phi))}{r_\odot^2}=\frac{r^4}{r_\odot^2}-\frac{r^4\cos^2(\phi)}{r_\odot^2}=\frac{r^4}{r_\odot^2}-r^2\qquad(12.4.600)$$

hence:

$$\frac{r_{\odot}^2}{(r^2-r_{\odot}^2)}\mathrm{d}r^2=r^2\mathrm{d}\phi^2 \tag{12.4.601}$$

We can now rewrite the equation of the metric:

$$\begin{aligned}c^2\mathrm{d}t^2&=\frac{1}{\left(1-\dfrac{r_g}{r}\right)^2}\left(\mathrm{d}r^2+\left(1-\frac{r_g}{r}\right)r^2\mathrm{d}\phi^2\right)=\frac{\mathrm{d}r^2}{\left(1-\dfrac{r_g}{r}\right)^2}\left(1+\left(1-\frac{r_g}{r}\right)\frac{r_{\odot}^2}{(r^2-r_{\odot}^2)}\right)\\&=\frac{\mathrm{d}r^2}{\left(1-\dfrac{r_g}{r}\right)^2}\left(\frac{(r^2-r_{\odot}^2)+r_{\odot}^2}{(r^2-r_{\odot}^2)}-\frac{r_g}{r}\frac{r_{\odot}^2}{(r^2-r_{\odot}^2)}\right)=\frac{\mathrm{d}r^2}{\left(1-\dfrac{r_g}{r}\right)^2}\left(\frac{r^2}{(r^2-r_{\odot}^2)}-\frac{r_g}{r}\frac{r_{\odot}^2}{(r^2-r_{\odot}^2)}\right)\\&=\frac{\mathrm{d}r^2}{\left(1-\dfrac{r_g}{r}\right)^2}\frac{r^2}{(r^2-r_{\odot}^2)}\left(1-\frac{r_gr_{\odot}^2}{r^3}\right)\end{aligned} \tag{12.4.602}$$

Taking the square root:

$$c\mathrm{d}t=\frac{\mathrm{d}r}{\left(1-\dfrac{r_g}{r}\right)}\frac{r}{(r^2-r_{\odot}^2)^{1/2}}\left(1-\frac{r_gr_{\odot}^2}{r^3}\right)^{1/2} \tag{12.4.603}$$

Since $r>r_{\odot}$ and $r_g\ll 0$ then:

$$\frac{r_g}{r}\ll 1 \qquad \frac{r_gr_{\odot}^2}{r^3}\ll 1 \tag{12.4.604}$$

Therefore, we have using the Maclaurin developments (see section Sequences and Series page 1703) to the first order:

$$c\mathrm{d}t\cong\mathrm{d}r\left(1+\frac{r_g}{r}\right)\frac{r}{(r^2-r_{\odot}^2)^{1/2}}\left(1-\frac{1}{2}\frac{r_gr_{\odot}^2}{r^3}\right) \tag{12.4.605}$$

We have then:

$$\begin{aligned}\mathrm{d}t&\cong\left(\frac{1}{c}\mathrm{d}r+\frac{r_g}{cr}\mathrm{d}r\right)\left(\frac{r}{(r^2-r_{\odot}^2)^{1/2}}-\frac{1}{2}\frac{r_gr_{\odot}^2}{r^3}\frac{r}{(r^2-r_{\odot}^2)^{1/2}}\right)\\&=\frac{1}{c}\mathrm{d}r\frac{r}{(r^2-r_{\odot}^2)^{1/2}}+\frac{r_g}{cr}\mathrm{d}r\frac{r}{(r^2-r_{\odot}^2)^{1/2}}-\frac{1}{c}\mathrm{d}r\frac{1}{2}\frac{r_gr_{\odot}^2}{r^3}\frac{r}{(r^2-r_{\odot}^2)^{1/2}}\\&-\frac{r_g}{cr}\mathrm{d}r\frac{1}{2}\frac{r_gr_{\odot}^2}{r^3}\frac{r}{(r^2-r_{\odot}^2)^{1/2}}\end{aligned} \tag{12.4.606}$$

Finally, we get once condensed:

$$\mathrm{d}t\cong\frac{r}{c(r^2-r_{\odot}^2)^{1/2}}\mathrm{d}r+\frac{r_g}{c(r^2-r_{\odot}^2)^{1/2}}\mathrm{d}r-\frac{r_gr_{\odot}^2}{2cr^2(r^2-r_{\odot}^2)^{1/2}}\mathrm{d}r-\frac{r_g^2r_{\odot}^2}{2cr^3(r^2-r_{\odot}^2)^{1/2}}\mathrm{d}r \tag{12.4.607}$$

What it is traditional to write (we take out the $1/c$ of the different terms):

$$\mathrm{d}t\cong\frac{1}{c}e(r)\mathrm{d}r+\frac{1}{c}f(r)\mathrm{d}r-\frac{1}{c}g(r)\mathrm{d}r-\frac{1}{c}h(r)\mathrm{d}r \tag{12.4.608}$$

If there is no mass then space-time is flat and $r_g=0$. Therefore:

$$\mathrm{d}t\cong\frac{r}{c(r^2-r_{\odot}^2)^{1/2}}\mathrm{d}r \tag{12.4.609}$$

We can thus distinguish the classical time from the extra time generated by the curved space. The "delay" will therefore be given by:

$$\int\mathrm{d}t=\Delta t\cong\frac{1}{c}\int e(r)\mathrm{d}r+\frac{1}{c}\int f(r)\mathrm{d}r-\frac{1}{c}\int g(r)\mathrm{d}r-\frac{1}{c}\int h(r)\mathrm{d}r \tag{12.4.610}$$

Then, to integrate the four functions of r, we must place ourselves in a repository placed if possible at the center of the main body (the Sun typically) since the Schwarzschild metric is based on this hypothesis for recall. Thus, to know the delay of a luminous ray starting from the Sun and travelling to the Earth, we logically choose as the radius of departure that of the Sun itself and as the radius of arrival, the distance Sun-Earth (this will correspond once the primitives computed at the integration terminals).

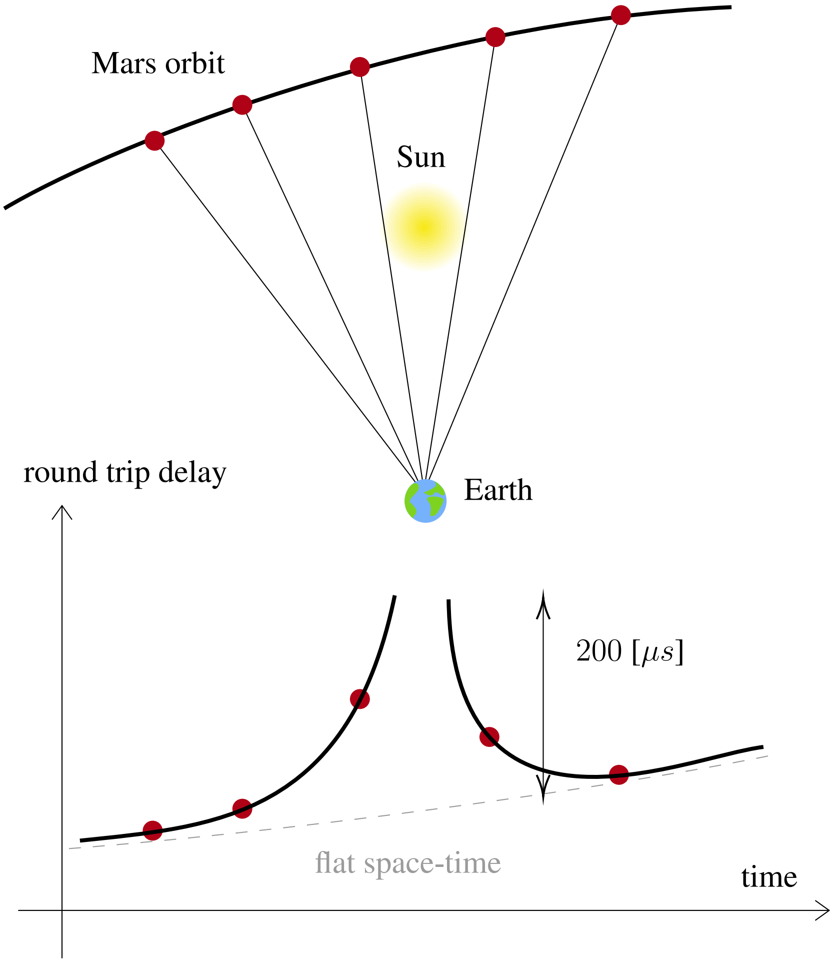

Figure 12.228: **Round-trip time of a signal as a function of the position of Mars**

Well that says it's nice to know the notations of use, but it's even better to do a numerical application! We will therefore first determine the primitive of each of the terms below:

$$\int\frac{r}{\sqrt{r^2-r_{\odot}^2}}\mathrm{d}r,\int\frac{r_g}{\sqrt{r^2-r_{\odot}^2}}\mathrm{d}r,\int\frac{r_gr_{\odot}^2}{2r^2\sqrt{r^2-r_{\odot}^2}}\mathrm{d}r,\int\frac{r_g^2r_{\odot}^2}{2r^3\sqrt{r^2-r_{\odot}^2}}\mathrm{d}r \tag{12.4.611}$$

The first two primitives are simple because they are usual primitives proved in detail in the section of Differential and Integral Calculus (see page 1534):

$$\begin{gathered}\int \frac{r}{\sqrt{r^2-r_\odot^2}}\mathrm{d}r=\sqrt{r^2-r_\odot^2}\\ \int \frac{r_g}{\sqrt{r^2-r_\odot^2}}\mathrm{d}r=r_g\operatorname{arccosh}\left(\frac{r}{r_\odot}\right)=r_g\ln\left(\frac{r}{r_\odot}+\sqrt{\frac{r^2}{r_\odot^2}-1}\right)\end{gathered}\tag{12.4.612}$$

where for the last primitive we have preserved the constant of integration (contrary to what was done in the section of Differential and Integral Calculus because $r_\odot\neq 1$).

Now it remains to us the last two integrals. Let's start in the order by:

$$\int \frac{r_g r_\odot^2}{2r^2\sqrt{r^2-r_\odot^2}}\mathrm{d}r=\frac{r_g r_\odot^2}{2}\int\frac{1}{r^2\sqrt{r^2-r_\odot^2}}\mathrm{d}r\tag{12.4.613}$$

By putting:

$$r=r_\odot\cosh(t)\qquad t=\operatorname{arccosh}\left(\frac{r}{r_\odot}\right)\qquad \mathrm{d}r=r_\odot\sinh(t)\mathrm{d}t\tag{12.4.614}$$

and using the results proved in the section of Differential and Integral Calculus, we then have:

$$\begin{aligned}\frac{r_g r_\odot^2}{2}\int\frac{1}{r^2\sqrt{r^2-r_\odot^2}}\mathrm{d}r&=\frac{r_g r_\odot^2}{2}\int\frac{r_\odot\sinh(t)}{r_\odot^2\cosh^2(t)\sqrt{r_\odot^2\cosh^2(t)-r_\odot^2}}\mathrm{d}t\\ &=\frac{r_g}{2}\int\frac{r_\odot\sinh(t)}{\cosh^2(t)\sqrt{r_\odot^2\sinh^2(t)}}\mathrm{d}t=\frac{r_g}{2}\int\frac{1}{\cosh^2(t)}\mathrm{d}t\\ &=\frac{r_g}{2}\tanh(t)=\frac{r_g}{2}\frac{\sinh(t)}{\cosh(t)}\\ &=\frac{r_g}{2}\frac{\sinh\left(\operatorname{arccosh}\left(\frac{r}{r_\odot}\right)\right)}{\cosh\left(\operatorname{arccosh}\left(\frac{r}{r_\odot}\right)\right)}=\frac{r_g}{2}\frac{\sinh\left(\operatorname{arccosh}\left(\frac{r}{r_\odot}\right)\right)}{\dfrac{r}{r_\odot}}\end{aligned}\tag{12.4.615}$$

Since we have (see section Trigonometry page 2519):

$$\sinh(x)=\sqrt{\cosh^2(x)-1}\tag{12.4.616}$$

Then:

$$\begin{aligned}\frac{r_g r_\odot^2}{2}\int\frac{1}{r^2\sqrt{r^2-r_\odot^2}}\mathrm{d}r&=\frac{r_g}{2}\frac{\sinh\left(\operatorname{arccosh}\left(\frac{r}{r_\odot}\right)\right)}{\dfrac{r}{r_\odot}}\\ &=\frac{r_g}{2}\frac{\sqrt{\cosh^2\left(\operatorname{arccosh}\left(\frac{r}{r_\odot}\right)\right)-1}}{\dfrac{r}{r_\odot}}\\ &=\frac{r_g}{2}\frac{\sqrt{\left(\frac{r}{r_\odot}\right)^2-1}}{\dfrac{r}{r_\odot}}=\frac{r_g}{2}\frac{\dfrac{\sqrt{r^2-r_\odot^2}}{r_\odot}}{\dfrac{r}{r_\odot}}=r_g\frac{\sqrt{r^2-r_\odot^2}}{2r}\end{aligned}\tag{12.4.617}$$

Finally, it remains the last primitive:

$$\int \frac{r_g^2 r_\odot^2}{2r^3\sqrt{r^2-r_\odot^2}}\mathrm{d}r=\frac{r_g^2 r_\odot^2}{2}\int \frac{1}{r^3\sqrt{r^2-r_\odot^2}}\mathrm{d}r=\frac{r_g^2 r_\odot^2}{2}\int \frac{1}{r^4\sqrt{1-\left(\frac{r_\odot}{r}\right)^2}}\mathrm{d}r \tag{12.4.618}$$

We put for what will follow:

$$r=\frac{r_\odot}{x} \qquad \mathrm{d}r=-\frac{r_\odot}{x^2}\mathrm{d}x \tag{12.4.619}$$

Therefore it comes:

$$\begin{aligned}\frac{r_g^2 r_\odot^2}{2}\int \frac{1}{r^4\sqrt{1-\left(\frac{r_\odot}{r}\right)^2}}\mathrm{d}r&=\frac{r_g^2}{2r_\odot}\int \frac{-x^2}{\sqrt{1-x^2}}\mathrm{d}x=\frac{r_g^2}{2r_\odot}\int \frac{1-x^2-1}{\sqrt{1-x^2}}\mathrm{d}x\\&=\frac{r_g^2}{2r_\odot}\left[\int \sqrt{1-x^2}\mathrm{d}x-\int \frac{1}{\sqrt{1-x^2}}\mathrm{d}x\right]\end{aligned} \tag{12.4.620}$$

In the section of Differential and Integral Calculus (see page 1534) we have proved that:

$$\int \sqrt{1-x^2}\mathrm{d}x=\frac{1}{2}\arcsin(x)+\frac{x}{2}\sqrt{1-x^2} \tag{12.4.621}$$

and that:

$$\int \frac{1}{\sqrt{1-x^2}}\mathrm{d}x=\arcsin(x) \tag{12.4.622}$$

Therefore:

$$\begin{aligned}&\frac{r_g^2}{2r_\odot}\left[\int \sqrt{1-x^2}\mathrm{d}x-\int \frac{1}{\sqrt{1-x^2}}\mathrm{d}x\right]=\frac{r_g^2}{2r_\odot}\left[\frac{1}{2}\arcsin(x)+\frac{x}{2}\sqrt{1-x^2}-\arcsin(x)\right]\\&=\frac{r_g^2}{2r_\odot}\left[\frac{x}{2}\sqrt{1-x^2}-\frac{1}{2}\arcsin(x)\right]\end{aligned} \tag{12.4.623}$$

To return to the integral of the beginning we remember that $r=\dfrac{r_\odot}{x}$. Therefore:

$$\int \frac{r_g^2 r_\odot^2}{2r^3\sqrt{r^2-r_\odot^2}}\mathrm{d}r=\frac{r_g^2}{2r_\odot}\left[\frac{r_\odot}{2r^2}\sqrt{r^2-r_\odot^2}-\frac{1}{2}\arcsin\left(\frac{r_\odot}{r}\right)\right] \tag{12.4.624}$$

We thus finally have by taking all the primitives calculated above and by choosing a starting and finishing terminal for the calculation:

$$\Delta t=\frac{1}{c}\left[\sqrt{r^2-r_\odot^2}+r_g\ln\left(\frac{r_\odot}{r}+\sqrt{\frac{r^2}{r_\odot^2}-1}\right)-r_g\frac{\sqrt{r^2-r_\odot^2}}{2r}-\frac{r_g^2}{2r_\odot}\left[\frac{r_\odot}{2r^2}\sqrt{r^2-r_\odot^2}-\frac{1}{2}\arcsin\left(\frac{r_\odot}{r}\right)\right]\right]_{R_0}^{R_1} \tag{12.4.625}$$

We see in the Newtonian limit case where $r_g=0$ that this relation is reduced to:

$$\Delta t\cong\frac{1}{c}\sqrt{r^2-r_\odot^2}\Big|_{R_0}^{R_1}=\frac{1}{c}\left(\sqrt{R_0^2-r_\odot^2}-\sqrt{R_1^2-r_\odot^2}\right) \tag{12.4.626}$$

So for a round trip (between planet and satellite for example), then it comes in this simplified case:

$$\boxed{\Delta t \cong \frac{2}{c}\left(\sqrt{R_0^2 - r_\odot^2} - \sqrt{R_1^2 - r_\odot^2}\right)} \tag{12.4.627}$$

In November 1976 (holocene calendar), when the two Viking spacecraft were operating on the surface of Mars, the planet went behind the Sun as seen from Earth (see figure below). Scientists had preprogrammed Viking to send a radio wave toward Earth that would go extremely close to the outer regions of the Sun (actually a G2V-type star, aka yellow dwarf). According to General Relativity there would be a delay because the radio wave would be passing through a region where time ran more slowly. The experiment was able to confirm Einstein's theory to within 0.1%.

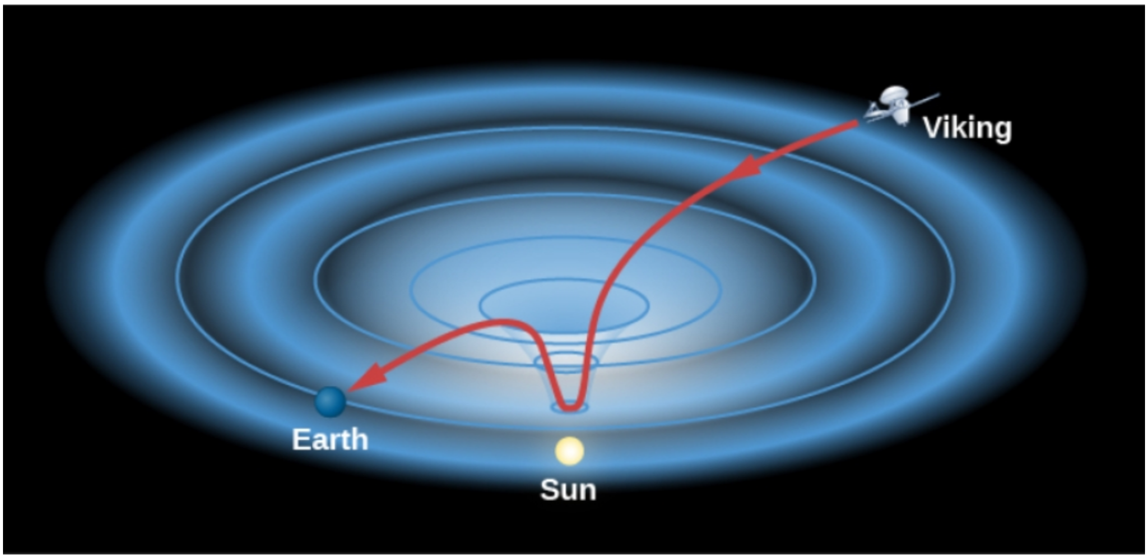

Figure 12.229: **Radio signals from the Viking lander on Mars were delayed when they passed near the Sun (source: OpenStax)**

In 12003 (holocene calendar), with the space probe Cassini an accuracy of 0.0012% was achieved (see [55])!

12.4.6.5 Hafele–Keating experiment (general relativity version)

The Hafele–Keating experiment was a test of the theory of relativity as we already know (see section Special Relativity page 5664). In October 11971 (holocene calendar), Joseph C. Hafele, a physicist, and Richard E. Keating, an astronomer, took four cesium-beam atomic clocks aboard commercial airliners. They flew twice around the world, first eastward, then westward, and compared the clocks against others that remained at the United States Naval Observatory. When reunited, the three sets of clocks were found to disagree with one another, and their differences were consistent with the predictions of special and General Relativity (GR).

It is therefore a macroscopic realization of the famous "twins paradox". We propose in the following to establish the predictions of General Relativity with respect to the relative aging of clocks, based on a simplified aircraft trajectory.

General Relativity predicts an additional effect, in which an increase in gravitational potential due to altitude speeds the clocks up. That is, clocks at higher altitude tick faster than clocks on Earth's surface. This effect has been confirmed in many tests of General Relativity, such as the Pound–Rebka experiment and Gravity Probe A. In the Hafele–Keating experiment, there was a slight increase in gravitational potential due to altitude that tended to speed the clocks back up. Since the aircraft flew at roughly the same altitude in both directions, this effect was approximately the same for the two planes, but nevertheless it caused a difference in comparison to the clocks on the ground.

The results were published in Science in 11972 (holocene calendar):

	Nanoseconds ([ns]) gained, predicted				
	Gravitational (GR)	**Kinematic (SR)**	**Total**	**[ns] gained measured**	**Δ**
Eastward	$+144\pm 14$	-184 ± 18	-40 ± 23	-59 ± 10	0.76σ
Westward	$+179\pm 18$	$+96\pm 10$	$+275\pm 7$	$+273\pm 7$	0.09σ

as available in [220].

The published outcome of the experiment was consistent with Special and General Relativity. The observed time gains and losses were different from zero to a high degree of confidence, and were in agreement with relativistic predictions to within the $\sim 10\%$ precision of the experiment.

It is assumed that in the vicinity of the Earth, the metric tensor is given by the Schwarzschild metric is to say that there exists a system of coordinates $(x^\mu)=(ct,r,\theta,\phi)$, named Schwarzschild coordinates, such that:

$$g_{\mu\nu}x^\mu x^\nu=\mathrm{d}s^2=\left(1-\frac{2GM}{c^2r}\right)c^2\mathrm{d}t^2-\frac{1}{\left(1-\dfrac{2GM}{c^2r}\right)}\mathrm{d}r^2-r^2\left(\mathrm{d}\theta^2+\sin^2(\theta)\mathrm{d}\phi^2\right) \quad (12.4.628)$$

For what will follow, by tradition, we will take the $(-+++)$ metric:

$$g_{\mu\nu}x^\mu x^\nu=\mathrm{d}s^2=-\left(1-\frac{2GM}{c^2r}\right)c^2\mathrm{d}t^2+\frac{1}{\left(1-\dfrac{2GM}{c^2r}\right)}\mathrm{d}r^2+r^2\left(\mathrm{d}\theta^2+\sin^2(\theta)\mathrm{d}\phi^2\right) \quad (12.4.629)$$

where we will take $G\cong 6.67\cdot 10^{-11}\,[\mathrm{m}^3\cdot\mathrm{kg}^{-1}\cdot\mathrm{s}^{-2}]$ and $c\cong 3\cdot 10^8\,[\mathrm{m}\cdot\mathrm{s}^{-1}]$ and $M=5.972\cdot 10^{24}\,[\mathrm{kg}]$.

Ok now we need two results, first the 4-vector speed:

$$u^\alpha=(u^0,u^1,u^2,u^3)=\frac{\mathrm{d}x^\alpha}{\mathrm{d}\tau} \quad (12.4.630)$$

since $u^0=c$.

Now before we continue, consider the following result (with the $(-,+,+,+)$ metric):

$$u_\mu u^\mu=g_{\mu\nu}u^\mu u^\nu=g_{\mu\nu}\frac{\mathrm{d}x^\mu}{\mathrm{d}\tau}\frac{\mathrm{d}x^\nu}{\mathrm{d}\tau}=\frac{g_{\mu\nu}\mathrm{d}x^\mu\mathrm{d}x^\nu}{\mathrm{d}\tau^2}=\frac{\mathrm{d}s^2}{\mathrm{d}\tau^2}=\frac{c^2\mathrm{d}\tau^2}{\mathrm{d}\tau^2}=-c^2 \quad (12.4.631)$$

But:

$$g_{\mu\nu}u^{\mu}u^{\nu}=-\left(1-\frac{2GM}{c^2r}\right)(u^0)^2+\frac{1}{\left(1-\dfrac{2GM}{c^2r}\right)}(u^r)^2+r^2\left((u^{\theta})^2+\sin^2(\theta)(u^{\phi})^2\right) \tag{12.4.632}$$

Equating we get obviously:

$$-\left(1-\frac{2GM}{c^2r}\right)(u^0)^2+\frac{1}{\left(1-\dfrac{2GM}{c^2r}\right)}(u^r)^2+r^2\left((u^{\theta})^2+\sin^2(\theta)(u^{\phi})^2\right)=-c^2 \tag{12.4.633}$$

Explicitly:

$$-\left(1-\frac{2GM}{c^2r}\right)(u^0)^2+\frac{1}{\left(1-\dfrac{2GM}{c^2r}\right)}\left(\frac{\mathrm{d}r}{\mathrm{d}\tau}\right)^2+r^2\left(\left(\frac{\mathrm{d}\theta}{\mathrm{d}\tau}\right)^2+\sin^2(\theta)\left(\frac{\mathrm{d}\phi}{\mathrm{d}\tau}\right)^2\right)=-c^2 \tag{12.4.634}$$

But as:

$$u^0=c\frac{\mathrm{d}t}{\mathrm{d}\tau} \tag{12.4.635}$$

Thus:

$$(u^0)^2\left[1+\frac{2GM}{c^2r}+\frac{1}{\left(1-\dfrac{2GM}{c^2r}\right)}\left(\frac{\mathrm{d}r}{\mathrm{d}\tau}\right)^2\left(\frac{c\mathrm{d}t}{\mathrm{d}\tau}\right)^{-2}+r^2\left(\left(\frac{\mathrm{d}\theta}{\mathrm{d}\tau}\right)^2\left(\frac{c\mathrm{d}t}{\mathrm{d}\tau}\right)^{-2}+\sin^2(\theta)\left(\frac{\mathrm{d}\phi}{\mathrm{d}\tau}\right)^2\left(\frac{c\mathrm{d}t}{\mathrm{d}\tau}\right)^{-2}\right)\right]=-c^2 \tag{12.4.636}$$

After a first simplification:

$$(u^0)^2\left[-1+\frac{2GM}{c^2r}+\frac{1}{\left(1-\dfrac{2GM}{c^2r}\right)}\left(\frac{\mathrm{d}r}{c\mathrm{d}t}\right)^2+r^2\left(\left(\frac{\mathrm{d}\theta}{c\mathrm{d}t}\right)^2+\sin^2(\theta)\left(\frac{\mathrm{d}\phi}{c\mathrm{d}t}\right)^2\right)\right]=-c^2 \tag{12.4.637}$$

After another simplification and little notation simplification:

$$\left(\frac{c\mathrm{d}t}{\mathrm{d}\tau}\right)^2\left[-1+\frac{2GM}{c^2r}+\frac{1}{\left(1-\dfrac{2GM}{c^2r}\right)}\frac{\dot{r}^2}{c^2}+r^2\left(\frac{\dot{\theta}^2}{c^2}+\sin^2(\theta)\frac{\dot{\phi}^2}{c^2}\right)\right]=-c^2 \tag{12.4.638}$$

That is:

$$\mathrm{d}t^2\left[1-\frac{2GM}{c^2r}-\frac{1}{\left(1-\dfrac{2GM}{c^2r}\right)}\frac{\dot{r}^2}{c^2}-r^2\left(\frac{\dot{\theta}^2}{c^2}+\sin^2(\theta)\frac{\dot{\phi}^2}{c^2}\right)\right]=\mathrm{d}\tau^2 \tag{12.4.639}$$

Therefore:

$$\mathrm{d}t=\frac{1}{\sqrt{1-\dfrac{2GM}{c^2r}-\dfrac{1}{\left(1-\dfrac{2GM}{c^2r}\right)}\dfrac{\dot{r}^2}{c^2}-r^2\left(\dfrac{\dot{\theta}^2}{c^2}+\sin^2(\theta)\dfrac{\dot{\phi}^2}{c^2}\right)}}\mathrm{d}\tau \tag{12.4.640}$$

That we will write as:

$$\mathrm{d}t=\frac{1}{\sqrt{1+\left[-\dfrac{2GM}{c^2r}-\dfrac{1}{\left(1-\dfrac{2GM}{c^2r}\right)}\dfrac{\dot{r}^2}{c^2}-r^2\left(\dfrac{\dot{\theta}^2}{c^2}+\sin^2(\theta)\dfrac{\dot{\phi}^2}{c^2}\right)\right]}}\mathrm{d}\tau \tag{12.4.641}$$

Now as $r>R_{\oplus}$ (we take $R=6.4\cdot 10^6$ [m]), we have $GM/c^2r\cong 7\cdot 10^{-10}$. That means globally, we have also if the planes are not at a relativistic speed:

$$\frac{\dot{r}}{c^2}\ll 1,\frac{r^2\dot{\theta}^2}{c^2}\ll 1,\frac{r^2\dot{\phi}}{c^2}\ll 1,\frac{GM}{c^2r}\ll 1 \tag{12.4.642}$$

Then as all the terms in the square brackets are much more smaller than 1 we will use the Maclaurin development (see section Sequences and Series page 1703):

$$\frac{1}{\sqrt{1+x}}\cong 1-\frac{1}{2}x \tag{12.4.643}$$

Then:

$$\mathrm{d}t\cong\left(1+\frac{GM}{c^2r}+\frac{1}{\left(1-\dfrac{GM}{2c^2r}\right)}\frac{\dot{r}^2}{2c^2}+r^2\left(\frac{\dot{\theta}^2}{2c^2}+\sin^2(\theta)\frac{\dot{\phi}^2}{2c^2}\right)\right)\mathrm{d}\tau \tag{12.4.644}$$

We will also put $\left(1-\dfrac{GM}{2c^2r}\right)^{-1}\cong 1$. Therefore:

$$\mathrm{d}t\cong\left(1+\frac{GM}{c^2r}+\frac{\dot{r}^2}{2c^2}+r^2\left(\frac{\dot{\theta}^2}{2c^2}+\sin^2(\theta)\frac{\dot{\phi}^2}{2c^2}\right)\right)\mathrm{d}\tau \tag{12.4.645}$$

That is more convenient to write as:

$$\mathrm{d}t\cong\left(1+\frac{GM}{c^2r}+\frac{1}{2c^2}\left(\dot{r}+r^2\dot{\theta}^2+r^2\sin^2(\theta)\dot{\phi}^2\right)\right)\mathrm{d}\tau \tag{12.4.646}$$

Therefore:

$$\Delta\tau=\int_{t_1}^{t_2}\mathrm{d}\tau\cong\int_{t_1}^{t_2}\frac{1}{\left(1+\dfrac{GM}{c^2r}+\dfrac{1}{2c^2}\left(\dot{r}^2+r^2\dot{\theta}^2+r^2\sin^2(\theta)\dot{\phi}^2\right)\right)}\mathrm{d}t \tag{12.4.647}$$

Then using the Maclaurin development (see section Sequences and Series page 1703):

$$\frac{1}{1+x}\cong 1-x \tag{12.4.648}$$

We have:

$$\Delta\tau\cong\int\limits_{t_1}^{t_2}\left(1-\frac{GM}{c^2r}-\frac{1}{2c^2}\left(\dot{r}^2+r^2\dot{\theta}^2+r^2\sin^2(\theta)\dot{\phi}^2\right)\right)\mathrm{d}t \tag{12.4.649}$$

For the observer who remains on the ground, we have:

$$r=R=c^{te},\dot{r}=0,\theta=c^{te},\dot{\theta}=0,\dot{\phi}=\Omega=\frac{2\pi}{T}=c^{te}=7.3\cdot 10^{-5}\,[\text{rad}\cdot\text{s}^{-1}] \tag{12.4.650}$$

Therefore:

$$\begin{aligned}\Delta\tau_{\text{ground}}&\cong\int\limits_{t_1}^{t_2}\left(1-\frac{GM}{c^2r}-\frac{1}{2c^2}\left(\dot{r}^2+r^2\dot{\theta}^2+r^2\sin^2(\theta)\dot{\phi}^2\right)\right)\mathrm{d}t=\int\limits_{t_1}^{t_2}\left(1-\frac{GM}{c^2R}-\frac{R^2\sin^2(\theta)\Omega^2}{2c^2}\right)\mathrm{d}t\\&=\left(1-\frac{GM}{c^2R}-\frac{R^2\sin^2(\theta)\Omega^2}{2c^2}\right)\int\limits_{t_1}^{t_2}\mathrm{d}t=\left(1-\frac{GM}{c^2R}-\frac{\Omega^2R^2\sin^2(\theta)}{2c^2}\right)\Delta t\end{aligned} \tag{12.4.651}$$

Now for the airplane we have:

$$r=R+h=c^{te},\dot{r}=0,\theta=c^{te},\dot{\theta}=0 \tag{12.4.652}$$

and we assume non-relativistic speed of the airplane and the Newtonian addition of speed such that:

$$r\sin(\theta)\dot{\phi}_{\text{airplance}}\cong v_{\text{airplane}}+r\sin(\theta)\dot{\phi}_{\text{ground}}=v_{\text{airplane}}+r\Omega\sin(\theta)=v_{\text{airplane}}+(R+h)\Omega\sin(\theta)=c^{te} \tag{12.4.653}$$

Therefore:

$$\begin{aligned}\Delta\tau_{\text{airplane}}&\cong\int\limits_{t_1}^{t_2}\left(1-\frac{GM}{c^2r}-\frac{1}{2c^2}\left(\dot{r}^2+r^2\dot{\theta}^2+r^2\sin^2(\theta)\dot{\phi}^2\right)\right)\mathrm{d}t\\&=\int\limits_{t_1}^{t_2}\left(1-\frac{GM}{c^2(R+h)}-\frac{(v_{\text{airplane}}+(R+h)\Omega\sin(\theta))^2}{2c^2}\right)\mathrm{d}t\\&=\left(1-\frac{GM}{c^2(R+h)}-\frac{(v_{\text{airplane}}+(R+h)\Omega\sin(\theta))^2}{2c^2}\right)\int\limits_{t_1}^{t_2}\mathrm{d}t\\&=\left(1-\frac{GM}{c^2(R+h)}-\frac{(v_{\text{airplane}}+(R+h)\Omega\sin(\theta))^2}{2c^2}\right)\Delta t\end{aligned} \tag{12.4.654}$$

Now let us calculate the ratio:

$$\frac{\Delta\tau_{\text{airplane}}}{\Delta\tau_{\text{ground}}}\cong\frac{\left(1-\dfrac{GM}{c^2(R+h)}-\dfrac{(v_{\text{airplane}}+(R+h)\Omega\sin(\theta))^2}{2c^2}\right)\Delta t}{\left(1-\dfrac{GM}{c^2R}-\dfrac{\Omega^2R^2\sin^2(\theta)}{2c^2}\right)\Delta t} \tag{12.4.655}$$

Obviously, we see that the Δt will vanish! We use also again (...):

$$\frac{1}{1+x}\cong 1-x \tag{12.4.656}$$

Then:

$$\frac{\Delta\tau_{\text{airplane}}}{\Delta\tau_{\text{ground}}}\cong\left(\left(1-\frac{GM}{c^2(R+h)}-\frac{(v_{\text{airplane}}+(R+h)\Omega\sin(\theta))^2}{2c^2}\right)\right)\left(1+\frac{GM}{c^2R}+\frac{\Omega^2R^2\sin^2(\theta)}{2c^2}\right) \tag{12.4.657}$$

If we neglect all terms in $1/c^4$ it will remain:

$$\begin{aligned}\frac{\Delta\tau_{\text{airplane}}}{\Delta\tau_{\text{ground}}}&\cong 1-\frac{GM}{c^2(R+h)}-\frac{(v_{\text{airplane}}+(R+h)\Omega\sin(\theta))^2}{2c^2}+\frac{GM}{c^2R}+\frac{\Omega^2R^2\sin^2(\theta)}{2c^2}\\&=1-\frac{GM}{c^2(R+h)}-\frac{1}{2c^2}\left[v_{\text{airplane}}^2+2v_{\text{airplane}}(R+h)\Omega\sin(\theta)+(R+h)^2\Omega^2\sin^2(\theta)\right]+\frac{GM}{c^2R}+\frac{\Omega^2R^2\sin^2(\theta)}{2c^2}\end{aligned} \tag{12.4.658}$$

Neglecting the terms involving Ω^2 that are very small, it remains:

$$\begin{aligned}\frac{\Delta\tau_{\text{airplane}}}{\Delta\tau_{\text{ground}}}&\cong 1-\frac{GM}{c^2(R+h)}-\frac{1}{2c^2}\left[v_{\text{airplane}}^2+2v_{\text{airplane}}(R+h)\Omega\sin(\theta)\right]+\frac{GM}{c^2R}\\&=1+\frac{GMh}{c^2R(R+h)}-\frac{1}{2c^2}\left[v_{\text{airplane}}^2+2v_{\text{airplane}}(R+h)\Omega\sin(\theta)\right]\end{aligned} \tag{12.4.659}$$

Now if $R\gg h$ we can write:

$$\frac{\Delta\tau_{\text{airplane}}}{\Delta\tau_{\text{ground}}}\cong 1+\frac{GMh}{c^2R^2}-\frac{1}{2c^2}\left[v_{\text{airplane}}^2+2v_{\text{airplane}}R\Omega\sin(\theta)\right] \tag{12.4.660}$$

Let us subtract -1 on both side of equality:

$$\frac{\Delta\tau_{\text{airplane}}}{\Delta\tau_{\text{ground}}}-1\cong\frac{GMh}{c^2R^2}-\frac{1}{2c^2}\left[v_{\text{airplane}}^2+2v_{\text{airplane}}R\Omega\sin(\theta)\right] \tag{12.4.661}$$

That is:

$$\frac{\Delta\tau_{\text{airplane}}-\Delta\tau_{\text{ground}}}{\Delta\tau_{\text{ground}}}-1\cong\frac{GMh}{c^2R^2}-\frac{1}{2c^2}\left[v_{\text{airplane}}^2+2v_{\text{airplane}}R\Omega\sin(\theta)\right] \tag{12.4.662}$$

That is more often written:

$$\boxed{\frac{\Delta\tau_{\text{airplane}}-\Delta\tau_{\text{ground}}}{\Delta\tau_{\text{ground}}}-1\cong\frac{GM}{c^2R}\frac{h}{R}-\frac{v_{\text{airplane}}}{c^2}\left(\frac{v_{\text{airplane}}}{2}+R\Omega\sin(\theta)\right)} \tag{12.4.663}$$

The first term (with $h=10,000$ [m] and $R=6,371$ [km] and $c=299,792,458\,[\text{m}\cdot\text{s}^{-1}]$):

$$\frac{GM}{c^2R}\frac{h}{R}\cong 1.091\cdot 10^{-12} \tag{12.4.664}$$

is a pure gravitational effect, always positive, that we already know under the name "gravitational time dilatation", implies that the observer in the aircraft ages faster than the observer on the ground, the latter being deeper in the gravitational field of the Earth. This term is here because of our General Relativity approach!

The second term:

$$-\frac{v_{\text{airplane}}}{c^2}\left(\frac{v_{\text{airplane}}}{2}+R\Omega\sin(\theta)\right) \tag{12.4.665}$$

Corresponds to the dilatation of the times of the moving bodies in Special Relativity.

For a practical numerical application we will take again (see section Special Relativity page 5664):

$$v_{\text{airplane}} \cong 220\,[\mathrm{m}\cdot\mathrm{s}^{-1}] \tag{12.4.666}$$

and the total flight also of 41 hour according to measurement on the ground:

$$\Delta t = 147,600\,[\mathrm{s}] \tag{12.4.667}$$

and latitude of 38° (Washington airport) corresponding to a colatitude $\theta = 52°$. Then we have for the flight to the East ($v_{\text{airplane}} \cong +220\,[\mathrm{m}\cdot\mathrm{s}^{-1}]$):

$$-\frac{v_{\text{airplane}}}{c^2}\left(\frac{v_{\text{airplane}}}{2}+R\Omega\sin(\theta)\right) \cong -1.16\cdot 10^{-12} \tag{12.4.668}$$

and for the flight to the West ($v_{\text{airplane}} \cong -220\,[\mathrm{m}\cdot\mathrm{s}^{-1}]$):

$$-\frac{v_{\text{airplane}}}{c^2}\left(\frac{v_{\text{airplane}}}{2}+R\Omega\sin(\theta)\right) \cong 62.44\cdot 10^{-12} \tag{12.4.669}$$

Thus we have:

$$\begin{aligned}\frac{\Delta\tau_{\text{airplane,East}}-\Delta\tau_{\text{ground}}}{\Delta\tau_{\text{ground}}}-1 &\cong \frac{GM}{c^2R}\frac{h}{R}-\frac{v_{\text{airplane}}}{c^2}\left(\frac{v_{\text{airplane}}}{2}+R\Omega\sin(\theta)\right)\cong -7.1\cdot 10^{-14}\\ \frac{\Delta\tau_{\text{airplane,West}}-\Delta\tau_{\text{ground}}}{\Delta\tau_{\text{ground}}}-1 &\cong \frac{GM}{c^2R}\frac{h}{R}-\frac{v_{\text{airplane}}}{c^2}\left(\frac{v_{\text{airplane}}}{2}+R\Omega\sin(\theta)\right)\cong 1.72\cdot 10^{-12}\end{aligned} \tag{12.4.670}$$

To estimate $\Delta\tau_{\text{East}}$ and $\Delta\tau_{\text{West}}$ we just have to multiply the relative values above by the total duration of the flight:

$$\begin{aligned}\Delta\tau_{\text{East}} &\cong -10.48\,[\mathrm{ns}]\\ \Delta\tau_{\text{West}} &\cong +253\,[\mathrm{ns}]\end{aligned} \tag{12.4.671}$$

Comparing with the data in the statement, and the result we get with this experiment treatment in the Special Relativity section we draw two conclusions:

1. The above results, based on the very simplified trajectories of the airplanes (their altitude not being constant and their speed either) are in relatively good agreement with the theoretical predictions based on the real trajectories, that is to say using:

   $$\Delta\tau_{\text{airplane}} = \int_{t_1}^{t_2}\left(1-\frac{GM}{c^2(R+h)}-\frac{(v_{\text{airplane}}+(R+h)\Omega\sin(\theta))^2}{2c^2}\right)\mathrm{d}t \tag{12.4.672}$$

   rather than the very very very (...) approximate relation:

   $$\frac{\Delta\tau_{\text{airplane}}-\Delta\tau_{\text{ground}}}{\Delta\tau_{\text{ground}}}-1 \cong \frac{GM}{c^2R}\frac{h}{R}-\frac{v_{\text{airplane}}}{c^2}\left(\frac{v_{\text{airplane}}}{2}+R\Omega\sin(\theta)\right) \tag{12.4.673}$$

2. The results we get just here are less accurate relatively to measurement than the results we get using Special Relativity. Indeed, measurement give $\Delta\tau_{\text{West}}=+273\pm 7$ [ns], our Special Relativity treatment $\Delta\tau_{\text{West}}=+265$ [ns] and we get here $\Delta\tau_{\text{West}}=+253$ [ns], so we lost accuracy with the above approximation for the West. The measurement give $\Delta\tau_{\text{East}}=-59\pm 10$ [ns], our Special Relativity treatment $\Delta\tau_{\text{West}}=+156$ [ns] and we get here $\Delta\tau_{\text{West}}=+10.48$ [ns], so we gain accuracy with the above approximation for the East.

12.4.6.6 Black Holes

Some physicists suspect Black Holes might not exist outside theorists' imaginations. Skeptics argued that Black Holes might be only an artifact of General Relativity's subtle math, or that they might only form under unrealistic conditions, such as the collapse of a perfectly spherical star. However, in the late 11960s (holocene calendar), Roger Penrose dispelled such doubts with rigorous math, for which he shared the 12020 (holocene calendar) Nobel Prize in Physics. Penrose exactly proved that, no, no, even if you have a lumpy thing, as long as the density became high enough, it was going to collapse to a Black Hole!

There are four types of Black Holes that have quite very different characteristics:

- **Schwarzschild Black Holes:** That have zero angular momentum (non-rotating), they are quite unrealistic and unlikely because most things in the universe have an angular momentum. Schwarzschild Black Holes have a punctual singularity, they are spherically symmetric with no electric charge.
- **Kerr Black Holes:** That have an angular momentum (rotating), they are quite much more realistic and likely than Schwarzschild Black Holes as most things in the universe have an angular momentum. Kerr Black Holes are described by the Kerr metric and doesn't have a punctual singularity. The angular momentum causes the Kerr Black Holes to exhibit properties such as frame-dragging and the presence of an inner and outer event horizon.
- **Reissner-Nordstrom Black Holes:** They are non-rotating Black Holes (like Schwarzschild Black Holes) but with an electric charge.
- **Kerr-Newman Black Holes:** They are rotating Black Holes (like Kerr Black Holes) but with an electric charge.

Actually the texts below deal only with Schwarzschild Black Holes as the maths for the other Black Holes are quite more complicated to introduce. They will very likely be available for the next edition of this textbook!

But the doubts, as always in Science, subsist. Scientists hope to answer three specific questions at the day we write this textbook: Do the actual observed Black Holes really have event horizons? Are they as featureless as the no-hair theorem says? And do they distort space-time exactly as the Kerr metric predicts? The future will tell us!

Remark

Actually the nearest confirmed Black Hole to our Solar System is named Gaia BH1 (TIC 125470397), discovered in the year 12022 (holocene calendar) at a distance of $1,560\pm 10$ light-years in a binary system in the Unicorn constellation.

12.4.6.6.1 Schwarzschild Black Holes

But now let us focus on the basics. And for this purpose we stay focused on our Schwarzschild metric ....! We know that a radial trajectory of light-type implies:

$$\mathrm{d}s^2=0 \tag{12.4.674}$$

therefore:

$$\left(1-\frac{2GM}{c^2r}\right)c^2\mathrm{d}t^2-\frac{1}{\left(1-\dfrac{2GM}{c^2r}\right)}\mathrm{d}r^2-r^2\left(\mathrm{d}\theta^2+\sin^2(\theta)\mathrm{d}\phi^2\right)=0 \tag{12.4.675}$$

and in a direct radial trajectory (by definition!) we also have:

$$\mathrm{d}\theta=0 \quad \text{and} \quad \mathrm{d}\phi=0 \tag{12.4.676}$$

therefore:

$$\left(1-\frac{2GM}{c^2r}\right)c^2\mathrm{d}t^2-\frac{1}{\left(1-\dfrac{2GM}{c^2r}\right)}\mathrm{d}r^2=0 \tag{12.4.677}$$

Therefore:

$$\left(1-\frac{2GM}{c^2r}\right)c^2\mathrm{d}t^2=\frac{1}{\left(1-\dfrac{2GM}{c^2r}\right)}\mathrm{d}r^2 \tag{12.4.678}$$

hence:

$$\frac{\mathrm{d}t^2}{\mathrm{d}r^2}=\frac{1}{\left(1-\dfrac{2GM}{c^2r}\right)^2c^2} \tag{12.4.679}$$

so that:

$$\frac{\mathrm{d}t}{\mathrm{d}r}=\pm\frac{1}{c}\left(1-\frac{2GM}{c^2r}\right)^{-1} \tag{12.4.680}$$

Let us change to natural units $c=1$. It then comes:

$$\frac{\mathrm{d}t}{\mathrm{d}r}=\pm\frac{1}{\left(1-\dfrac{2GM}{r}\right)} \tag{12.4.681}$$

When $r\rightarrow 2GM$ the right-hand side of this equality tends to $\pm\infty$, then the evolution of time t (external observer) as a function of r tends to infinity with respect to the proper time of light.

The sphere given by the radius:

$$\boxed{r=R_S=\frac{2GM}{c^2}} \tag{12.4.682}$$

defines the "horizon" of a "Schwarzschild Black Hole".

Towards this limit boundary, the light seems to put an infinite time compared to an external observer to move when approaching a Black Hole. It therefore never really reaches it in relation to the observer, hence the fact that the Black Holes can be surrounded according to their environment by a luminous halo near the Schwarzschild radius. Moreover, since time seems to be stopped, the frequency of the light surrounding the Black Hole tends towards zero and therefore towards the infra-red.

A Black Hole is therefore a region of space-time exhibiting such strong gravitational effects that nothing—not even particles and electromagnetic radiation such as light—can escape from inside it. The theory of General Relativity predicts that a sufficiently compact mass can deform space-time to form a Black Hole. The boundary of the region from which no escape is possible is named the "event horizon".

Objects whose gravitational fields are too strong for light to escape were first considered in the 118th century (holocene calendar) by John Michell and Pierre-Simon Laplace. The first modern solution of General Relativity that would characterize a Black Hole was found by Karl Schwarzschild in 11916 (holocene calendar), although its interpretation as a region of space from which nothing can escape was first published by David Finkelstein in 11958 (holocene calendar). Black Holes were long considered a mathematical curiosity; it was during the 11960s (holocene calendar) that theoretical work showed they were a generic prediction of General Relativity. The discovery of neutron stars sparked interest in gravitationally collapsed compact objects as a possible astrophysical reality.

Black Holes of stellar mass are expected to form when very massive stars collapse at the end of their life cycle. After a Black Hole has formed, it can continue to grow by absorbing mass from its surroundings. By absorbing other stars and merging with other Black Holes, supermassive Black Holes of millions of solar masses may form. There is general consensus that supermassive Black Holes exist in the centers of most galaxies.

Despite its invisible interior, the presence of a Black Hole can be inferred through its interaction with other matter and with electromagnetic radiation such as visible light. Matter that falls onto a Black Hole can form an external accretion disk heated by friction, forming some of the brightest objects in the universe. If there are other stars orbiting a Black Hole, their orbits can be used to determine the Black Hole's mass and location. Such observations can be used to exclude possible alternatives such as neutron stars. In this way, astronomers have identified numerous stellar Black Hole candidates in binary systems, and established that the radio source known as Sagittarius A*, at the core of our own Milky Way galaxy, contains a supermassive Black Hole of about 4.3 million solar masses.

Remark

If the Sun or any other celestial object collapse into a Black Hole, this doesn't affect its orbiting element as the Black Holes still have the same mass (only the density change) and Newton's law still remains valid at a quite significant distant of it. So it is wrong to imagine that if the Sun collapse into a Black Hole of 6 [km] diameter it would exert a more big gravitational force and that all planets turning around it will be sucked in.

A common question that should perhaps arise to some readers now is... : how does gravity escape a Black Hole? The answer to this questions should first make a distinction between gravitational field and gravitational waves that are perturbations of space-time and that can't indeed escape from the inside of the Black Hole but that are mathematically also generated outside of the latter. For the gravitational field... it must be understood that gravity does not "travel". In fact, gravity is the result of space-time distortion, it is space itself and isn't a thing that travels through space, and Black Holes distort space-time not only inside but outside their event horizon. Gravitational waves (see further below) by cons, travel a the speed of light and emerge when the distortion changes over time.

On 11 February 12016 (holocene calendar), the LIGO collaboration announced the first observation of gravitational waves; because these waves were generated from a Black Hole merger it was the first ever direct detection of a binary Black Hole merger. On 15 June 12016, a second detection of a gravitational wave event from colliding Black Holes was announced.

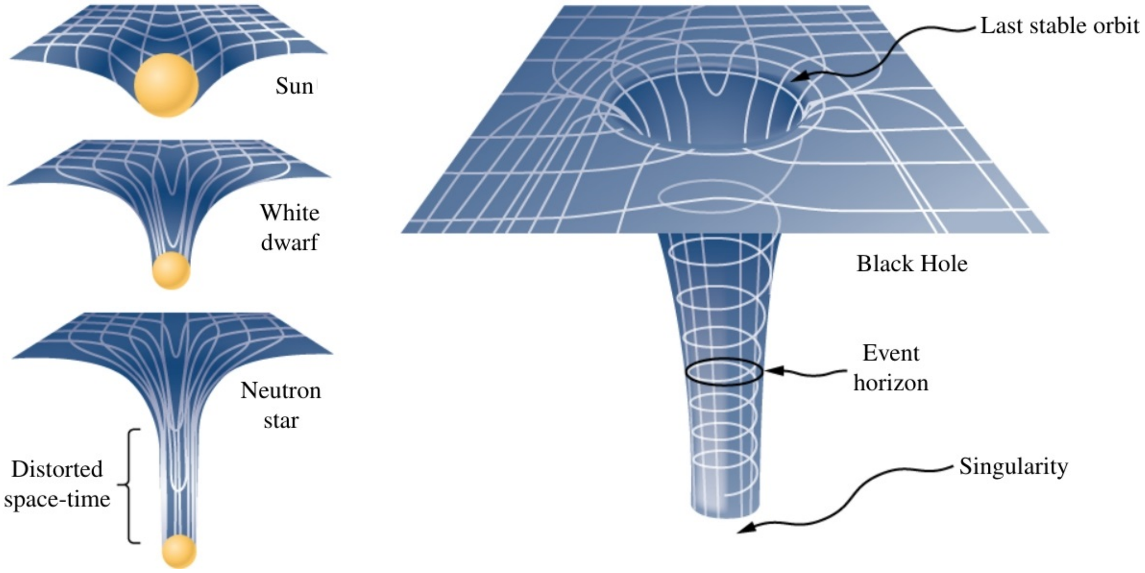

Figure 12.230: **2D naive representation of space curve near some celestial objects (source: OpenStax)**

The Galactic Center Group members have been measuring the positions of thousands of stars in the vicinity of the Galactic Center for more than 20 years. This unique data set allowed us to measure directly short-period orbits of stars. In particular, a full phase coverage has been measured for two stars: S0-2 with an orbital period of 15.56 years, and S0-102 with 11.5 years. At the closest approach, S0-2 is only 17 light hours away from the center of the Galaxy, about four times the distance of Neptune from the Sun. From these orbital data, we can determine the mass of the central Black Hole in our own Galaxy.

The Milky Way Galaxy center is the best candidate to what seems to a Black Hole, and especially and example of the closest supermassive Black Holes (SMBH), located at $\sim 25,000$ light years away from us and corresponds with the location of Sagittarius A* a bright and very compact astronomical radio source at the center of the Milky Way. Its mass is estimated to be 4 million times the mass of the Sun, which implies that the Schwarzschild radius is about 17 times that of Sun's radius. As a comparison, Mercury's orbit is located at a distance of ~ 83 solar radii. Because the Galactic Center is the site of the closest supermassive Black Hole by a factor of 100, it is a unique laboratory for solving some of the greatest mysteries associated with the fundamental physics of supermassive Black Holes and the role that they play in the formation and evolution of galaxies. Furthermore, it is the only galactic nucleus in which direct measurements of stellar orbits is possible, with either the current or the next-generation instruments.

Observations of stellar orbits around the Galactic Black Hole also yields precision measurement of the distance to the Galactic Center, which is important as it affects almost all questions not only of Galactic structure, dynamics and mass, but those of extragalactic distance scales and the value of Hubble's constant as well.

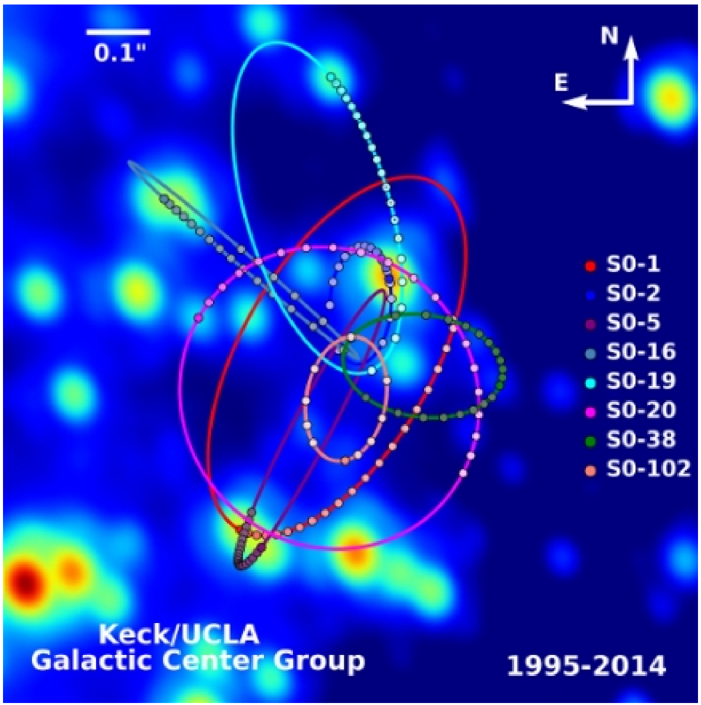

Figure 12.231: Orbits of stars within the central 1.0×1.0 arcseconds of our Galaxy (source: Galactic Group Center)

The origin of supermassive Black Holes and also the assumption that each galaxy center is a Black Hole remains an open field of research. Astrophysicists agree that once a Black Hole is in place in the center of a galaxy, it can grow by accretion of matter and by merging with other Black Holes this is why some observations gives for example for the hyperluminous quasar S5 0014+81 a weight of approximately $40 \cdot 10^{10}$ times the mass of the Sun.

Remark

The Schwarzschild radius scales with mass as $R_S = 2GM/c^2$. What might be defined as a "Schwarzschild volume" would then be $V_S = 4\pi R_S^3/3 = (32/3)\pi(GM/c^2)^3$. So the density of matter defined by the horizon is $\rho_S = (3/32)(c^2/G)^3 M^{-2}$. So the Schwarzschild density scales as the inverse square of the mass. A 10 billion solar mass Black Hole (like the estimation of the one at the center of our Galaxy) has a radius estimated about $1,010$ [km], or a Schwarzschild volume of $V_S \cong 10^{39}$ [m^3]. A solar mass is 10^{30} [kg] and the Schwarzschild density defined by the horizon is then $\rho_S = 10^{-9}$ [kg $\cdot$ m^{-3}]. That is actually quite small. However this may be misleading. "Density" suggests that the mass is distributed more or less uniformly within the Black Hole, and this is non-sense. The Black Hole is mostly empty, and all the mass is concentrated within a tiny region (classically a point) in the center of the Black Hole.

Are there any other magnitudes we should note or calculate in Black Hole physics and thermodynamics! Yes, there are Assuming spherical symmetry, we can calculate the Schwarzschild area or event horizon/surface area of the Schwarzschild's Black Hole simple by:

$$A_S = 4\pi R_S^2 = 4\pi \left(\frac{2GM}{c^2}\right)^2 = \frac{16\pi G^2 M^2}{c^4} \qquad (12.4.683)$$

We can also calculate the surface gravity κ, if the gravitational field of the Black Hole reads:

$$g = \frac{GM}{R^2} \qquad (12.4.684)$$

then, at the Schwarzschild radius it becomes the mentioned surface gravity $\kappa = g(R = R_S)$:

$$\kappa = \frac{c^4}{4GM} \qquad (12.4.685)$$

Interestingly, this surface gravity is $1/M$ the maximal force $c^4/4G$ allowed by natural units... What else? Surface tides, or more precisely, the tidal acceleration at the Black Hole surface. The tidal acceleration is calculated with (the reader notice that we take the version of the tidal force with the factor 2 instead of factor 4 as discusses during the proof of this relation in the section of Astronomy page 5358):

$$a_T = \frac{2GMd}{R^3} \qquad (12.4.686)$$

If it is evaluated at R_S we get:

$$a_T(\text{BH}) = a_T(R = d = R_S) = \frac{c^4}{2GM} \qquad (12.4.687)$$

12.4.6.6.1.1 Black Hole innermost stable circular orbit

The title of this subsection a bit a misnomer. Indeed, the results that we will see also applies to any other object that Black Holes!

Much of the modern folklore about Black Holes is misleading. One idea you may have heard is that Black Holes go about sucking things up with their gravity. Actually, it is only very close to a Black Hole that the strange effects we have been discussing come into play. The gravitational attraction far away from a Black Hole is the same as that of the star that collapsed to form it.

Remember that the gravity of any star some distance away acts as if all its mass were concentrated at a point in the center, which we name the "center of gravity". For real stars, we merely imagine that all mass is concentrated there; for Black Holes, all the mass really is concentrated at a point in the center.

So, if you are a star or distant planet orbiting around a star that becomes a Black Hole, your orbit may not be significantly affected by the collapse of the star (although it may be affected by any mass loss that precedes the collapse). If, on the other hand, you venture close to the event horizon, it would be very hard for you to resist the "pull" of the warped space-time near the Black Hole. You have to get really close to the Black Hole to experience any significant effect.

If another star or a spaceship were to pass one or two solar radii from a Black Hole, Newton's laws would be adequate to describe what would happen to it. Only very near the event horizon of a Black Hole is the gravitation so strong that Newton's laws break down. The Black Hole remnant of a massive star coming into our neighbourhood would be far, far safer to us than its earlier incarnation as a brilliant, hot star.

A Black Hole with it's accretion disk ray-traced with Python™[50] by Riccardo Antonelli:

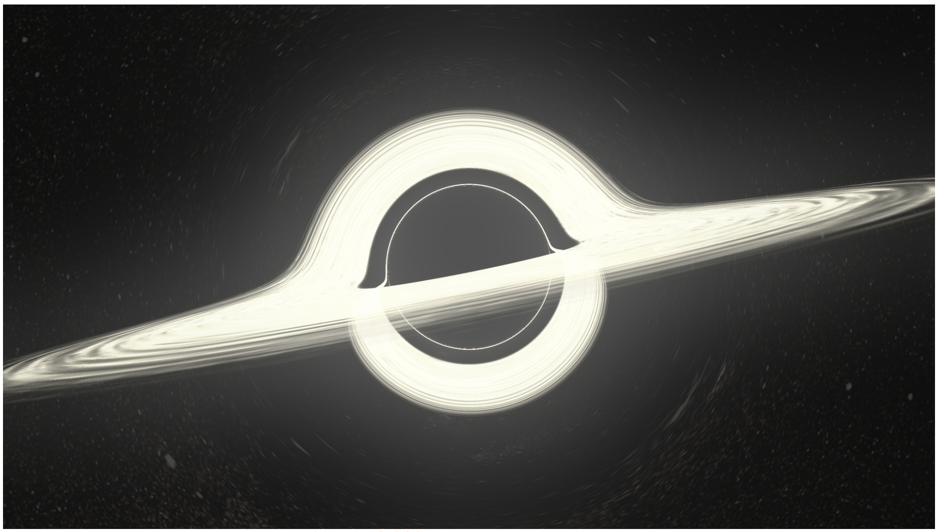

Figure 12.232: **Black Hole ray-traced**

To begin, let us recall first that we have just seen that Schwarzschild metric is an exact solution to the Einstein vacuum equation given by the line element:

$$\mathrm{d}s^2=\left(1-\frac{2GM}{c^2r}\right)c^2\mathrm{d}t^2-\frac{1}{\left(1-\dfrac{2GM}{c^2r}\right)}\mathrm{d}r^2-r^2\left(\mathrm{d}\theta^2+\sin^2(\theta)\mathrm{d}\phi^2\right) \qquad (12.4.688)$$

which written as a matrix consequently becomes:

$$g_{\mu\nu}=\begin{bmatrix}1-\dfrac{2GM}{rc^2} & 0 & 0 & 0\\ 0 & -\left(1-\dfrac{2GM}{rc^2}\right)^{-1} & 0 & 0\\ 0 & 0 & -r^2 & 0\\ 0 & 0 & 0 & -r^2\sin^2(\theta)\end{bmatrix} \qquad (12.4.689)$$

Now let us introduce a special mathematical vector in General Relativity.

Definition (#12.4.546): If all components of a metric are independent of some particular x^ν, then we have the "Killing vector" $\vec{K}$, named after Wilhelm Killing, with components $K^\mu=\delta^\mu_\nu$. That is, the contravariant form just has a constant in the appropriate slot and zeros elsewhere. As we will see, as Noether's theorem tells us (see section Analytical Mechanics page 3132) that for every symmetry there is a conserved quantity (energy, momentum, angular momentum, etc), Killing vectors are a powerful way to find those conserved quantities.

---

[50] Source code available on http://rantonels.github.io/starless

The Schwarzschild metric has a few interesting properties, it is clear that it is independent explicitly of t and ϕ and hence there exist Killing vectors that we will denote $K_1^\mu = (1,0,0,0)$ (often denoted ξ^μ) and $K_2^\mu = (0,0,0,1)$ (often denoted η^μ) which both lie along directions in which the metric doesn't change[51].

We define the velocity four-vector v^μ as:

$$u^\mu = \frac{\mathrm{d}x^\mu}{\mathrm{d}\tau} \tag{12.4.690}$$

where we let indices run over the coordinates (t,r,θ,ϕ) and τ is the proper time. Now, since the metric is independent of t, forming the scalar product between K_1^μ and $u_\mu = g_{\mu\nu}u^\nu$ gives the quantity:

$$g_{\mu\nu}K_1^\mu u^\nu = \left(1-\frac{GM}{rc^2}\right)u^0 = \left(1-\frac{GM}{rc^2}\right)\frac{c\mathrm{d}t}{\mathrm{d}\tau} \tag{12.4.691}$$

But we know from our study of Special Relativity that:

$$\frac{c\mathrm{d}t}{\mathrm{d}\tau} = \frac{1}{1-\left(\dfrac{v}{c}\right)^2} = c\gamma \tag{12.4.692}$$

Therefore:

$$g_{\mu\nu}K_1^\mu u^\nu = \left(1-\frac{GM}{rc^2}\right)c\gamma \tag{12.4.693}$$

Now let us recall that we have proved earlier that the Lagrangian of the geodesic was given by:

$$L = \frac{1}{2}mg_{\alpha\beta}\frac{\partial x^\alpha}{\partial\tau}\partial x^\beta\partial\tau = \frac{1}{2}mg_{\alpha\beta}\dot{x}^\alpha\dot{x}^\beta \tag{12.4.694}$$

Therefore:

$$L = \frac{1}{2}m\left[\left(1-\frac{2GM}{rc^2}\right)\dot{t}^2 - \left(1-\frac{2GM}{rc^2}\right)^2\dot{r}^2 - r^2\dot{\theta}^2 - r^2\sin^2(\theta)\dot{\phi}^2\right] \tag{12.4.695}$$

We see that the Lagrangian doesn't depend explicitly on t and ϕ so these two parameters implies conservation of energy.

But now we know from our study of Analytical Mechanics (see page 3181) that:

$$\frac{\partial L}{\partial\dot{q}} = p \tag{12.4.696}$$

That in our case will be written (as there is conservation according to component t):

$$\frac{\partial L}{\partial\dot{t}} = c^{te} \tag{12.4.697}$$

---

[51] There are actually four Killing vectors for the Schwarzschild metric since it is invariant under time translations and rotations. But we will only need two of them for our purpose.

Therefore:

$$m\left(1-\frac{2GM}{rc^2}\right)\dot{t}=c^{te} \tag{12.4.698}$$

Hence:

$$g_{\mu\nu}K_1^{\mu}u^{\nu}=\left(1-\frac{GM}{rc^2}\right)\frac{\mathrm{d}t}{\mathrm{d}\tau}=\left(1-\frac{GM}{rc^2}\right)u^t=\left(1-\frac{GM}{rc^2}\right)c\gamma=c^{te} \tag{12.4.699}$$

That we will denote with the lowercase letter e:

$$e=\left(1-\frac{GM}{rc^2}\right)u^t=c^{te} \tag{12.4.700}$$

and is an energy per unit rest mass.

Similarly since the metric is independent of ϕ we form:

$$g_{\mu\nu}K_2^{\mu}u^{\nu}=-r^2\sin^2(\theta)\frac{\mathrm{d}\phi}{\mathrm{d}\tau} \tag{12.4.701}$$

But we also know from our study of Analytical Mechanics that:

$$\frac{\partial L}{\partial \dot{q}}=p \tag{12.4.702}$$

And as our Lagrangian above is explicitly independent of ϕ, we have:

$$\frac{\partial L}{\partial \dot{\phi}}=-mr^2\sin^2(\theta)\dot{\phi}=p=c^{te} \tag{12.4.703}$$

Therefore we denote with the lowercase letter l:

$$l=g_{\mu\nu}K_2^{\mu}u^{\nu}=-r^2\sin^2(\theta)\frac{\mathrm{d}\phi}{\mathrm{d}\tau}=-r^2\sin^2(\theta)u^{\phi}=c^{te} \tag{12.4.704}$$

the angular momentum per unit rest mass.

This is exactly the kind of useful thing we need to consider particle orbits! The conserved energy and angular momentum are one of the fundamental descriptors for orbits from Classical Mechanics as we know!

Caution! The Friedmann-Robertson-Lemaître-Walker metric or the de Sitter metric have for example time-dependant factor, this prevents a time-like Killing vector and therefore conservation of energy! In the case of cosmologies, these metrics FLRW etc, are "type O Petrov-Penrose-Pirani solutions", which have no isometries or Killing vectors. There may be timelike Killing vectors on the patches associated with those metrics, but there is no global timelike Killing vector!

Now before we continue, consider the following result (with the $(+,-,-,-)$ metric):

$$u_{\mu}u^{\mu}=g_{\mu\nu}u^{\mu}u^{\nu}=g_{\mu\nu}\frac{\mathrm{d}x^{\mu}}{\mathrm{d}\tau}\frac{\mathrm{d}x^{\nu}}{\mathrm{d}\tau}=\frac{g_{\mu\nu}\mathrm{d}x^{\mu}\mathrm{d}x^{\nu}}{\mathrm{d}\tau^2}=\frac{\mathrm{d}s^2}{\mathrm{d}\tau^2}=\frac{c^2\mathrm{d}\tau^2}{\mathrm{d}\tau^2}=c^2 \tag{12.4.705}$$

that is for our geodesic observer a normalization constraint that will be useful to us in our study of the Borde-Guth-Vilenkin theorem (see section Cosmogony page 1383).

Remark

In textbooks this relation is often given with the $(-,+,+,+)$ signature and in natural units, thus:

$$u_\mu u^\mu = g_{\mu\nu} u^\mu u^\nu = -1 \tag{12.4.706}$$

Hence:

$$\left(1-\dfrac{2GM}{rc^2}\right)(u^t)^2-\left(1-\dfrac{2GM}{rc^2}\right)^{-1}(u^r)^2-r^2(u^\theta)^2-r^2\sin^2(\theta)(u^\phi)^2=c^2 \tag{12.4.707}$$

We are free to choose $\theta=\pi/2$, exploiting the spherical symmetry of Schwarzschild metric, to simplify the calculations (as $\sin(\pi/2)=1$) and since we fix that value, we also have $u^\theta=0$. Therefore the previous relation reduce to:

$$\left(1-\dfrac{2GM}{rc^2}\right)(u^t)^2-\left(1-\dfrac{2GM}{rc^2}\right)^{-1}(u^r)^2-r^2(u^\phi)^2=c^2 \tag{12.4.708}$$

Now we exploit the relations:

$$e=\left(1-\dfrac{GM}{rc^2}\right)u^t \qquad \text{and} \qquad l=-r^2\sin^2(\theta)u^\phi=-r^2u^\phi \tag{12.4.709}$$

That we inject in the previous one and we get:

$$\left(1-\dfrac{2GM}{rc^2}\right)^{-1}e^2-\left(1-\dfrac{2GM}{rc^2}\right)^{-1}(u^r)^2-\dfrac{l^2}{r^2}=c^2 \tag{12.4.710}$$

Or (this is the form as we found it the most often in textbooks):

$$-\left(1-\dfrac{2GM}{rc^2}\right)^{-1}e^2+\left(1-\dfrac{2GM}{rc^2}\right)^{-1}(u^r)^2+\dfrac{l^2}{r^2}=-c^2 \tag{12.4.711}$$

Multiplying both side by $-\left(1-\frac{2GM}{rc^2}\right)^{-1}$ we get first:

$$e^2-(u^r)^2-\left(1-\dfrac{2GM}{rc^2}\right)\dfrac{l^2}{r^2}=\left(1-\dfrac{2GM}{rc^2}\right)c^2 \tag{12.4.712}$$

Rearranging:

$$e^2-c^2=(u^r)^2+\left(1-\dfrac{2GM}{rc^2}\right)\dfrac{l^2}{r^2}-\dfrac{2GM}{r} \tag{12.4.713}$$

Dividing by 2 and developing:

$$\dfrac{e^2-c^2}{2}=(u^r)^2+\dfrac{l^2}{2r^2}-\dfrac{GMl^2}{r^3c^2}-\dfrac{GM}{r} \tag{12.4.714}$$

Remark

Sometimes we have the notation:

$$\frac{e^2-c^2}{2}=\mathcal{E} \tag{12.4.715}$$

That is more often written:

$$\frac{e^2-c^2}{2}=\left(\frac{\mathrm{d}r}{\mathrm{d}t}\right)^2+\left(\frac{l^2}{2r^2}-\frac{GM}{r}-\frac{GMl^2}{r^3c^2}\right)=\left(\frac{\mathrm{d}r}{\mathrm{d}t}\right)^2+U_{\text{eff}}(r) \tag{12.4.716}$$

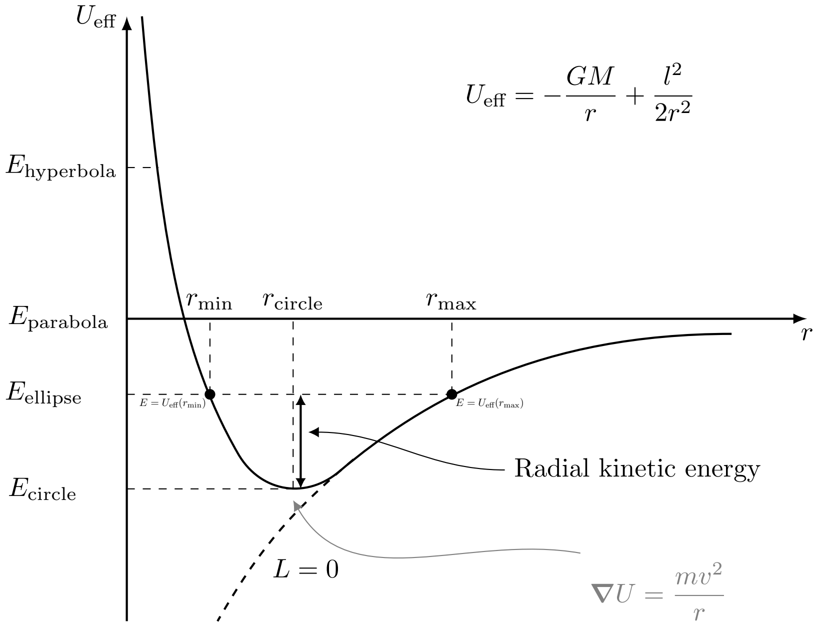
which is the radial equation in the Schwarzschild geometry with the corresponding effective potential:

$$\boxed{U_{\text{eff}}(r)=\frac{l^2}{2r^2}-\frac{GM}{r}-\frac{GMl^2}{r^3c^2}} \tag{12.4.717}$$

Thus, a system of four coupled differential equations in four variables has, with the help of three constants of the motion, been reduced to a single differential equation in one variable.

The equivalent classical effective potential is quite obviously:

$$U_{\text{eff}}(r)=\frac{l^2}{2r^2}-\frac{GM}{r} \tag{12.4.718}$$



U_{eff}
$U_{\text{eff}}=-\frac{GM}{r}+\frac{l^2}{2r^2}$
$E_{\text{hyperbola}}$
E_{parabola}
E_{ellipse}
E_{circle}
r_{min}
r_{circle}
r_{max}
r
$E=U_{\text{eff}}(r_{\text{min}})$
$E=U_{\text{eff}}(r_{\text{max}})$
Radial kinetic energy
$L=0$
$\nabla U=\frac{mv^2}{r}$

Figure 12.233: Classical effective gravitational potential profile

Remark

The prior-previous relation should be written more explicitly:

$$\frac{E^2-mc^2}{2}=m\left(\frac{\mathrm{d}r}{\mathrm{d}t}\right)^2+\left(\frac{ml^2}{2r^2}-\frac{GMm}{r}-\frac{GMml^2}{r^3c^2}\right) \tag{12.4.719}$$

It is also a very useful quantity to consider here because it is completely analogous to the effective potential from orbital theory seen in the section of Classical Mechanics (see page 3359).

Indeed, consider a particle of mass m orbiting a much heavier object of mass M. Assuming Newtonian mechanics can be used, and the motion of the larger mass is negligible, then the conservation of energy and angular momentum give two constants E and L, with values in polar coordinates:

$$E=E_c+E_p=\frac{1}{2}mv^2-\frac{GmM}{r}=12m\left(\dot{r}^2+r^2\dot{\phi}^2\right)-\frac{GmM}{r} \tag{12.4.720}$$

As the angular momentum is given by:

$$L=mr^2\dot{\phi} \tag{12.4.721}$$

Only two variables are needed, since the motion occurs in a plane. Substituting the second expression into the first and rearranging gives:

$$m\dot{r}^2=2E-\frac{L^2}{mr^2}+\frac{2GmM}{r}=2E-\frac{1}{r^2}\left(\frac{L^2}{m}-2GmMr\right) \tag{12.4.722}$$

Hence:

$$\frac{1}{2}m\dot{r}^2=E-U_{\text{eff}}(r) \tag{12.4.723}$$

That is:

$$E=\frac{1}{2}m\dot{r}^2+U_{\text{eff}}(r)=\frac{1}{2}m\left(\frac{\mathrm{d}r}{\mathrm{d}t}\right)^2+\left(\frac{L^2}{2mr^2}-\frac{GmM}{r}\right) \tag{12.4.724}$$

Therefore we see the analogy now! We have therefore indeed:

$$U_{\text{eff}}(r)=\underbrace{\frac{l^2}{2r^2}-\frac{GM}{r}}_{\text{Newtonian}}-\underbrace{\frac{GMl^2}{r^3c^2}}_{\text{GR correction}} \tag{12.4.725}$$

Remark

we therefore understand why in General Relativity the difference $\mathcal{E}-U_{\text{eff}}(r)$ is therefore interpreted as the kinetic energy.

So what does the extra correction from General Relativity? Look at a graph for $l/M=4.5$, below:

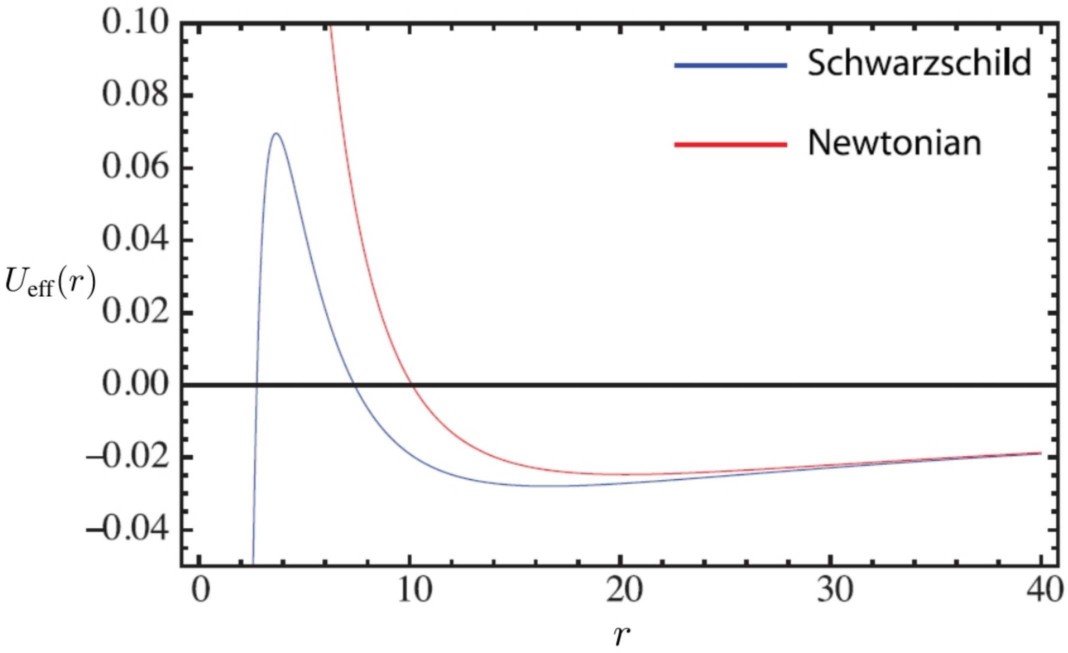


Figure 12.234: Effective potential profile accord to Newtonian and General Relativity mechanics

So what do we notice right away?

There is a minimum in the effective potential, just as in the Newtonian case. For a particle bound in this potential, there is a "stable circular orbit" at the minimum of the potential (it can be shown that this orbit is perfectly circular). At large distances we see that our effective potential tends to the Newtonian one!

However, when $r \rightarrow 0$ our effective potential is dominated by the r^{-3} term, which diverges temporarily. Then, there is a maximum in the effective potential, unlike in the Newtonian case (we then say that the "centrifugal barrier is not impenetrable"). There is an "unstable circular orbit" at the maximum in the potential and it can be show that then the orbit is elliptical and precess like Mercury do (the orbit is not closed).

The shape of this potential is controlled by the magnitude of the angular momentum l.

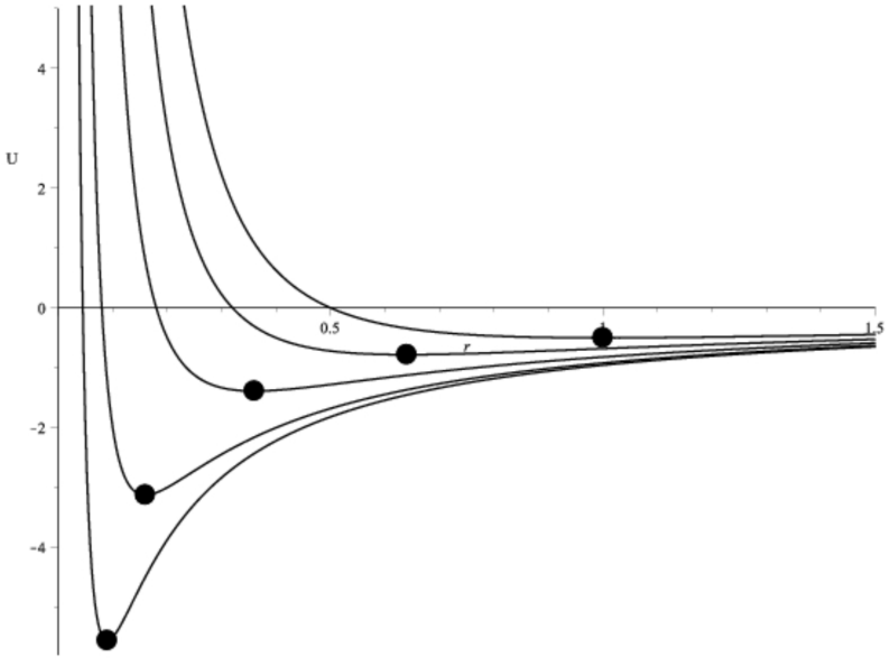

Figure 12.235: Newtonian effective potential for a test particle moving in the gravitational field of a central body with mass, for different values of angular momentum. Solid circles show position of minima corresponding to stable circular orbits.

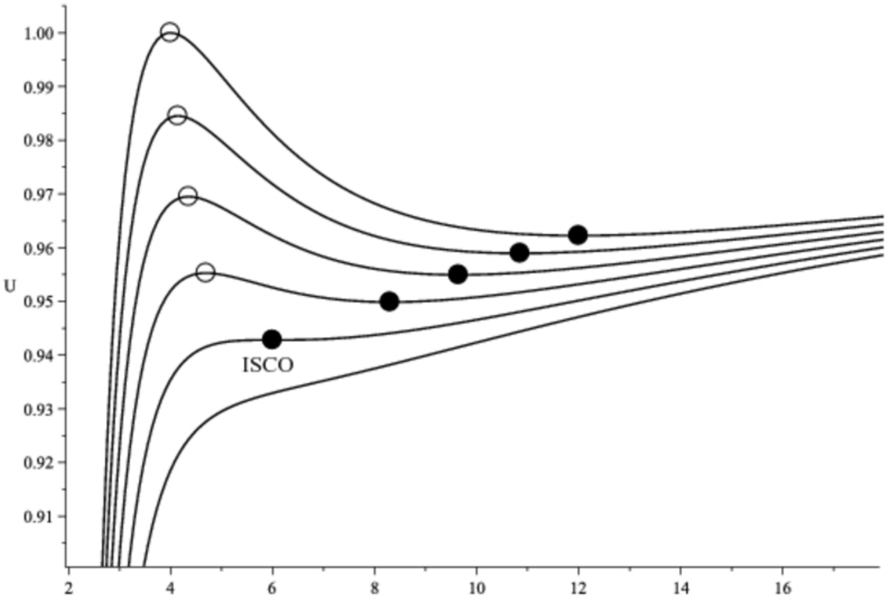

Figure 12.236: Effective potential (per unit particle rest mass) for motion in Schwarzschild metric. Maxima of potential are shown by circles, and minima are shown by solid circles.

We can find the min/max of the potential by constructing a radial derivative:

$$\frac{\mathrm{d}U_{\text{eff}}}{\mathrm{d}r}=0 \qquad (12.4.726)$$

Hence:

$$\frac{\mathrm{d}U_{\text{eff}}}{\mathrm{d}r}=-\frac{l^2}{r^3}+\frac{GM}{r^2}+3\frac{GMl^2}{r^4c^2}=0 \qquad (12.4.727)$$

We multiply both sides by r^4:

$$-l^2 r + GMr^2 + 2GMl^2c^2 = 0 \qquad (12.4.728)$$

This is a simple second degree polynomial, the solution is obviously (see section Calculus page 1383):

$$r_{\text{min,max}} = \frac{cl \pm \sqrt{l^2c^2 - 12G^2M^2}}{2Mc} \qquad (12.4.729)$$

The absolute minimum value for this occurs when[52]:

$$l = \frac{\sqrt{12}MG}{c} \qquad (12.4.730)$$

then:

$$\boxed{r_{\text{min}} = r_{\text{ISCO}} = \frac{6GM}{c^2} = 3R_S} \qquad (12.4.731)$$

where for recall R_S is the Schwarzschild radius. That latter relation is known as the ISCO, the "innermost stable circular orbit" (ISCO) or "marginally stable circular orbit" for the Schwarzschild geometry. We can see that it is equal to three times the Schwarzschild radius (hence, three times the event horizon radius of a Black Hole), for our Sun (if it was a Black Hole) this is almost equal to $9,000$ [km].

The effective potential in this case looks like:

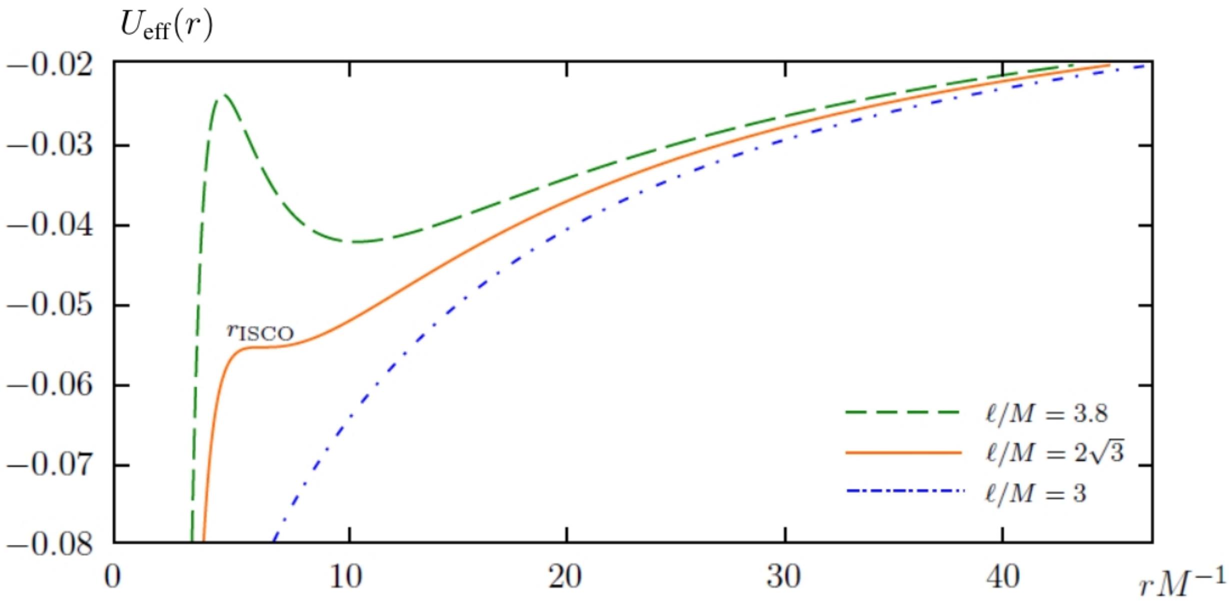

Figure 12.237: **Relativistic effective potentials for various values of l/M with $M = 1$**

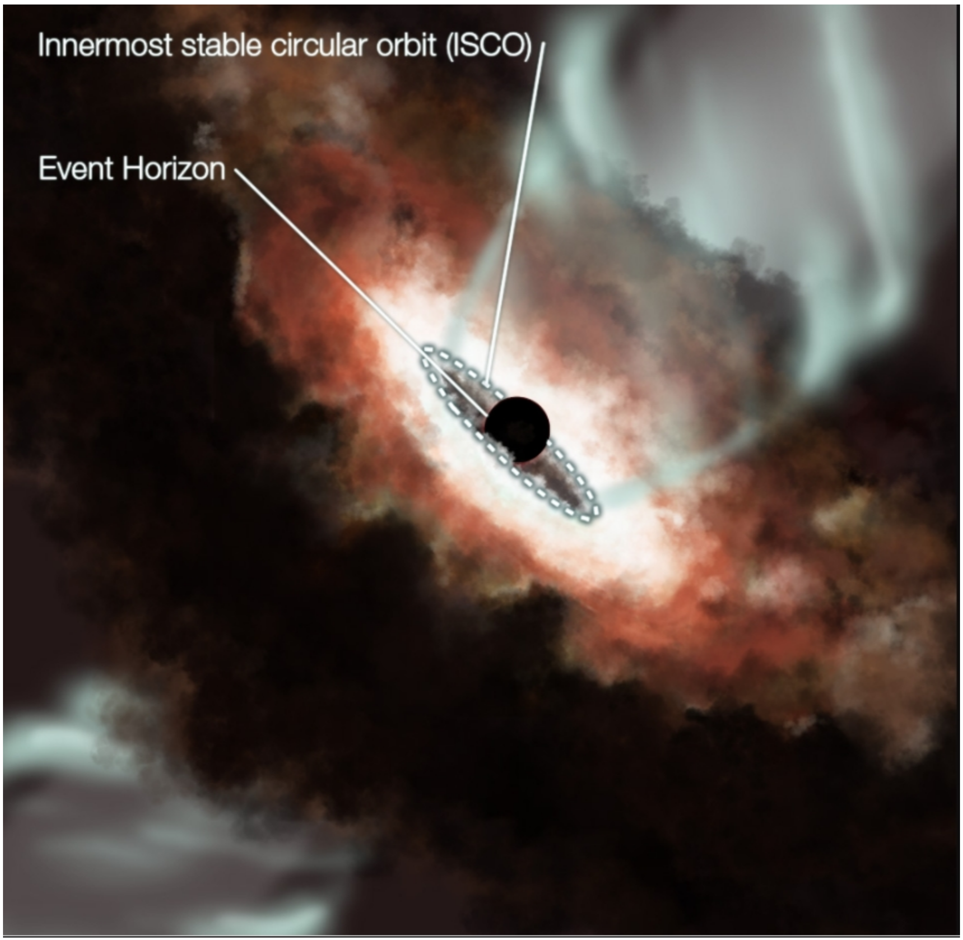
There are no stable circular orbits at radii smaller than r_{ISCO}. This has important astrophysical consequences when considering phenomena such as accretion — material slowly works its way down the gravitational potential, giving up energy and angular momentum until it accretes onto the central, compact object. If there is a minimum radius at which material (gas, in the accretion case) can stably orbit for example a Black Hole, it will plunge at all smaller radii for a given angular momentum. This bounds the amount of gravitational binding energy that can be extracted by a particle.

---

[52] Notice that if we put $G = c = 1$ we then have $l/M = \sqrt{12} = 2\sqrt{3}$

So we see this is a huge difference with Newtonian gravity where stable circular orbits are available at all R!

This artist's conception below shows the region hypothesised immediate surrounding a super-massive Black Hole (the black spot near the center). The Black Hole is orbited by a thick disk of hot gas. The center of the disk glows white-hot, while the edge of the disk is shown in dark silhouette. Magnetic fields channel some material into a jet-like outflow - the greenish wisps that extend to upper right and lower left. A dotted line marks the innermost stable circular orbit, which is the closest distance that material can orbit before becoming unstable and plunging into the Black Hole (hence sometimes the expression "plunging region"):



Innermost stable circular orbit (ISCO)
Event Horizon

Figure 12.238: **Black Hole innermost circular stable orbit illustration (source: Chris Fach, Perimeter Institute & University of Waterloo)**

Below the first direct reversed engineering capture of a Black Hole (in fact... of its surrounding), at the center of M87 the 12019-04-10 according to holocene calendar (National Science Foundation) using a planet-scale array of eight ground-based radio telescopes forged through international collaboration named the Event Horizon Telescope (EHT):

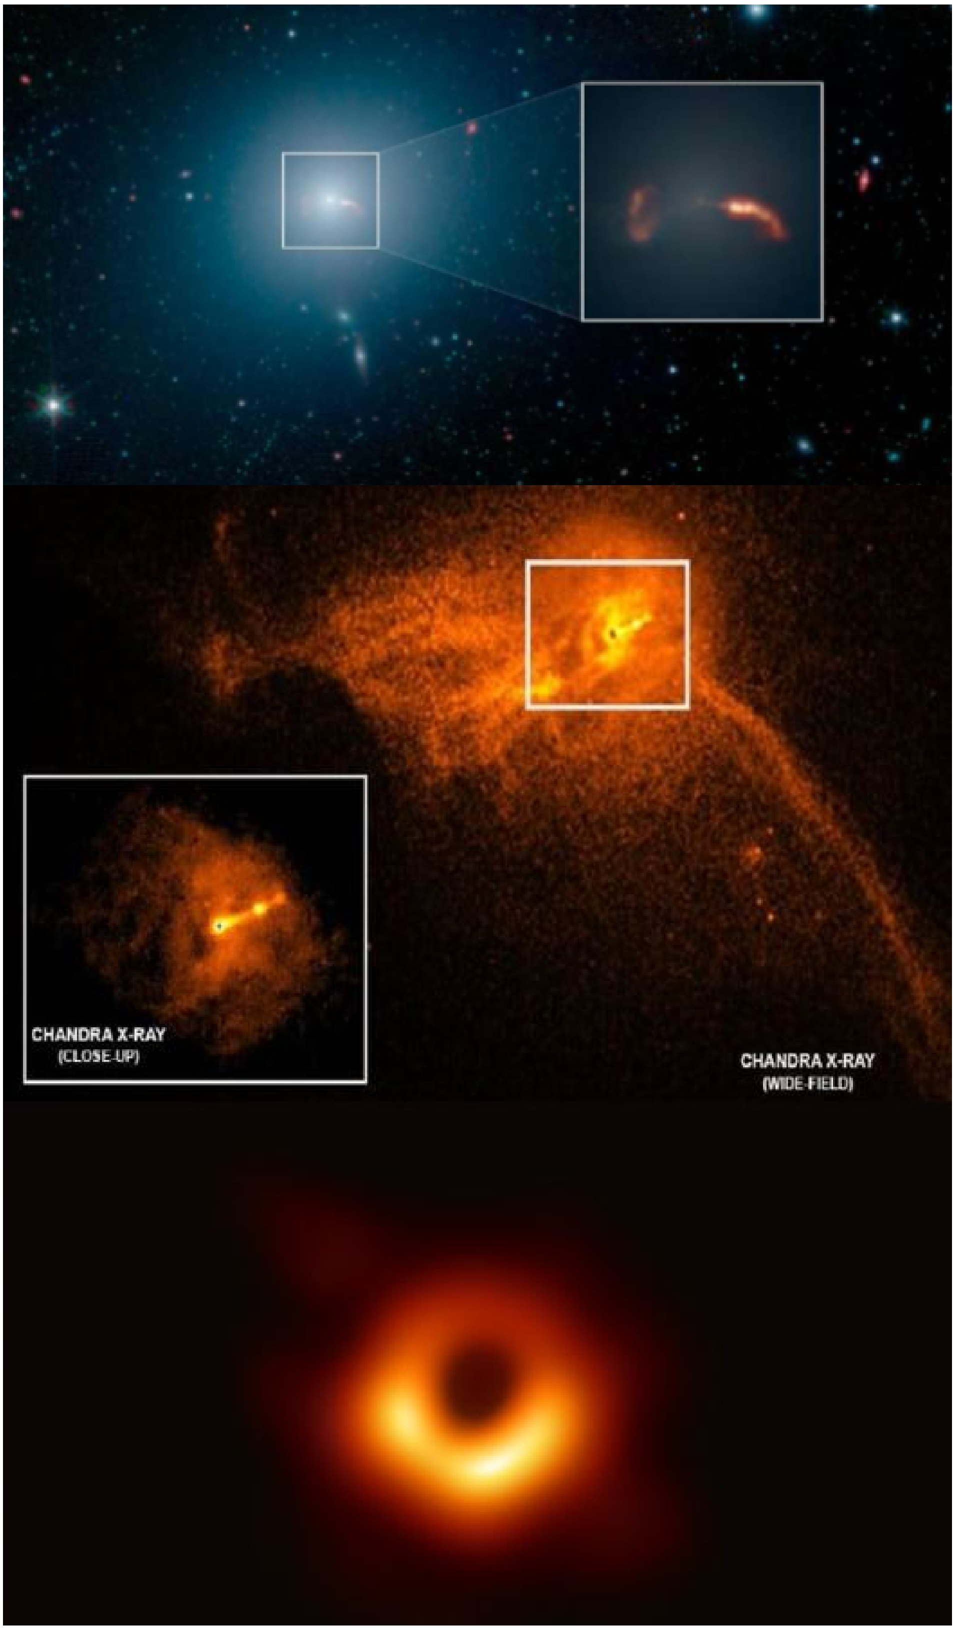


Figure 12.239: **First direct reversed engineering capture of a Black Hole, M87* the 12019-04-10 (source: National Science Foundation)**

On the left below we can see a composite simulated image (five years later than the above composite image, the 27 august 12024 according to holocene calendar) shows how M87* is seen by the Event Horizon Telescope at 86 [GHz] (red), 230 [GHz] (green), and 345 [GHz] (blue). On right, 345 [GHz] is seen in dark blue, a more compact and sharper view of the supermassive Black Holes, followed by 230 [GHz] in green, and 86 [GHz] in red. The higher the frequency, the sharper the image becomes, revealing structure, size, and shape that was previously less discernible (credit: EHT, D. Pesce, A. Chael, see [455]):

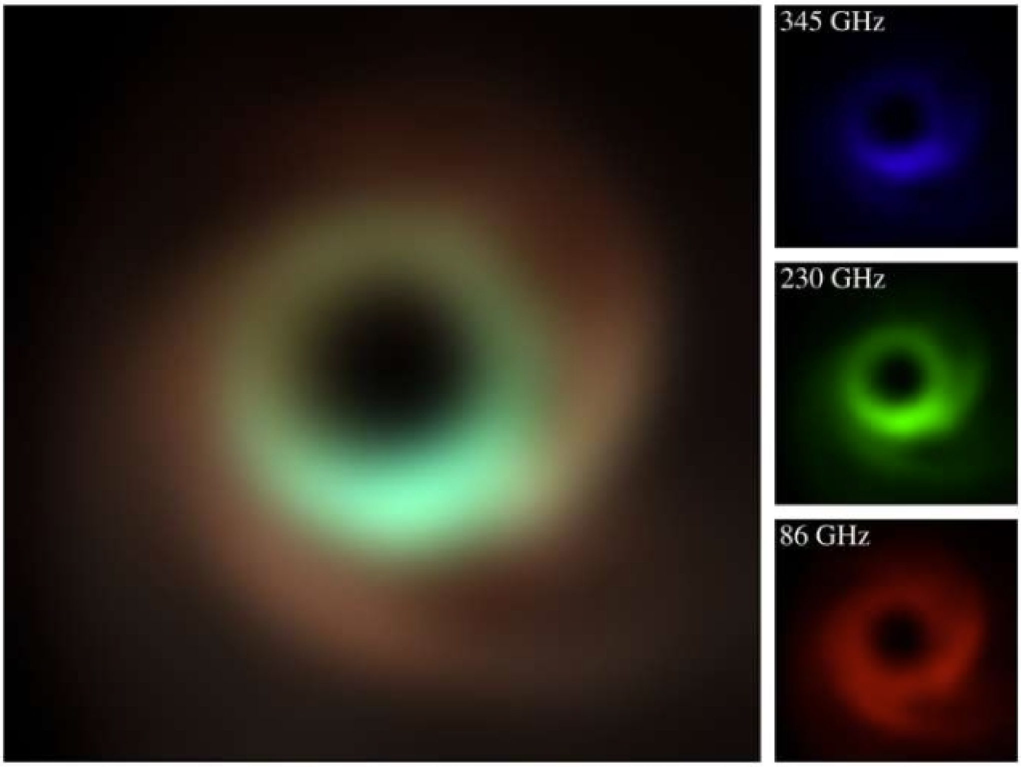

Figure 12.240: Most recent reversed composite image of the M87* Black Hole

Remark

A quite legitimate question would be at this state: If photons can't escape a Black Hole how then gravitons can do it? The answer is that as a force mediating particle, gravitons would come as virtual gravitons, just like virtual photons are the force exchange particles of the electromagnetic force. Virtual particles cannot be said to "travel" anywhere (no virtual photons move in between two interacting charged particles either). That is, they aren't created at one particle just to travel to another and 'exchange' forces between them. So one answer to your question is that nothing comes out of the Black Hole at all. No gravitons move from the Black Hole to the outside world. Unfortunately it's difficult to explain how virtual particles work, as they don't act like normal particles at all. They are better described as transient fluctuations of an underlying field that happen to be described by the same math that describes real particles. Furthermore the graviton is a hypothetical particle in theory of quantum gravity. General Relativity says nothing about gravitons, it just rather describes space-time as continuum.

12.4.6.6.1.2 Black Hole photon sphere

As photons approach the event horizon of a Black Hole, those with the appropriate energy avoid being pulled into the Black Hole (or possibly an "ultra-compact" neutron star) by travelling in a nearly tangential direction known as an "exit cone". A photon on the boundary of this cone does not possess the energy to escape the gravity well of the Black Hole. Instead, it orbits the Black Hole! These orbits are rarely stable in the long term.

The "photon sphere", also named "unstable photon sphere" or "photon ring", is as we will see located farther from the center of a Black Hole than the event horizon, but however nearest that the innermost stable orbit. Within a photon sphere, it is possible to imagine a photon that begins at the back of your head, orbiting the Black Hole, only then to be intercepted by your eyes, allowing you to see the back of your head.

In the previous development, if we focus of the innermost stable orbit, and especially on a photon (denoted γ) universe line, we have $\mathrm{d}s^2=0$, and then the result simplifies to:

$$U_{\gamma,\text{eff}}=\frac{l^2}{2r^2}-\frac{GMl^2}{r^3c^2} \tag{12.4.732}$$

Then following the same reasoning we get to find the min/max of the potential by constructing a radial derivative:

$$\frac{\mathrm{d}U_{\text{eff}}}{\mathrm{d}r}=0 \tag{12.4.733}$$

Hence:

$$\frac{\mathrm{d}U_{\text{eff}}}{\mathrm{d}r}=-\frac{l^2}{r^3}+3\frac{GMl^2}{r^4c^2}=0 \tag{12.4.734}$$

And rearranging gives:

$$\boxed{r_\gamma=\frac{3GM}{c^2}=\frac{3}{2}R_S<r_{\text{ISCO}}} \tag{12.4.735}$$

Therefore, for non-rotating Black Holes, the photon sphere is a sphere of radius $3/2R_S$, outside the event horizon but inside the innermost circular stable orbit.

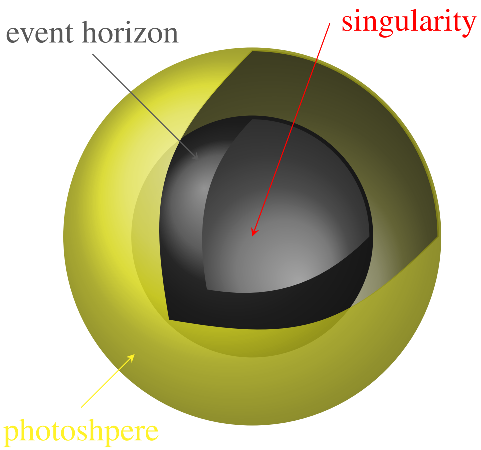

Figure 12.241: Photosphere and event horizon with correct proportions

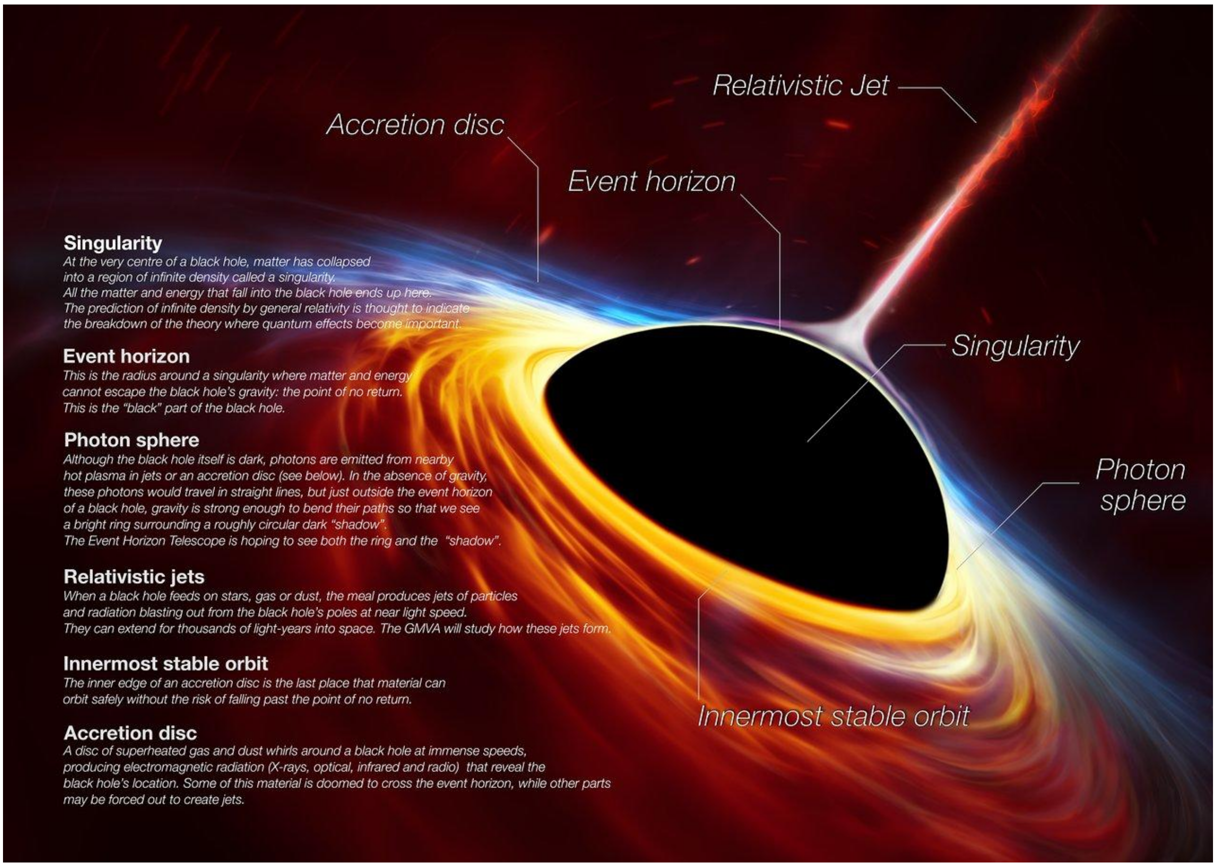
The latter relation is also sometimes named the "innermost bound circular orbit" (IBCO), which is the unstable (though still a bound) orbit and denoted r_{IBCO}.

And here is a summary of what we have seen so far (the summary is not perfect but it the best we have found so far):



Singularity
At the very centre of a black hole, matter has collapsed into a region of infinite density called a singularity. All the matter and energy that fall into the black hole ends up here. The prediction of infinite density by general relativity is thought to indicate the breakdown of the theory where quantum effects become important.

Event horizon
This is the radius around a singularity where matter and energy cannot escape the black hole's gravity: the point of no return. This is the "black" part of the black hole.

Photon sphere
Although the black hole itself is dark, photons are emitted from nearby hot plasma in jets or an accretion disc (see below). In the absence of gravity, these photons would travel in straight lines, but just outside the event horizon of a black hole, gravity is strong enough to bend their paths so that we see a bright ring surrounding a roughly circular dark "shadow". The Event Horizon Telescope is hoping to see both the ring and the "shadow".

Relativistic jets
When a black hole feeds on stars, gas or dust, the meal produces jets of particles and radiation blasting out from the black hole's poles at near light speed. They can extend for thousands of light-years into space. The GMVA will study how these jets form.

Innermost stable orbit
The inner edge of an accretion disc is the last place that material can orbit safely without the risk of falling past the point of no return.

Accretion disc
A disc of superheated gas and dust whirls around a black hole at immense speeds, producing electromagnetic radiation (X-rays, optical, infrared and radio) that reveal the black hole's location. Some of this material is doomed to cross the event horizon, while other parts may be forced out to create jets.

Figure 12.242: **Black Hole summary (source: Event Horizon Telescope website)**

12.4.6.6.1.3 Black Hole free fall proper time to singularity

Suppose we fall into a Schwarzschild Black Hole. According to General Relativity, we can compute the (finite) free fall time in which we travel from the Schwarzschild radius to the singularity (we assume by the moment General Relativity holds, the point is to what extend is this valid both in General Relativity and the real world, but we can do it as an exercise):

$$\boxed{t_s=\frac{1}{c}\int\limits_0^{R_S}\frac{1}{\sqrt{\dfrac{2GM}{c^2r}-1}}\mathrm{d}r=\frac{\pi}{2}\frac{R_S}{c}=\frac{\pi GM}{c^3}\cong\frac{M}{M_\odot}\cdot 1.54\cdot 10^{-5}\,[\mathrm{s}]}\tag{12.4.736}$$

That latter relation is the free fall radial path time to singularity for a non-rotating Black Hole!

Let us prove that:

$$\int\frac{1}{\sqrt{\dfrac{1}{x}-1}}\mathrm{d}x=-\sqrt{\frac{1}{x}-1}x-\frac{1}{2}\tan^{-1}\left(\sqrt{\frac{1}{x}-1}\right)+c^{te}\tag{12.4.737}$$

For this let us substitute:

$$u=\sqrt{\frac{1}{x}-1}\Leftrightarrow x=\frac{1}{u^2+1}\tag{12.4.738}$$

Then:

$$\mathrm{d}x=-2x^2\sqrt{\frac{1}{x}-1}\mathrm{d}u\tag{12.4.739}$$

Therefore:

$$\int\frac{1}{\sqrt{\dfrac{1}{x}-1}}\mathrm{d}x=\int\frac{-2x^2\sqrt{\dfrac{1}{x}-1}}{\sqrt{\dfrac{1}{x}-1}}\mathrm{d}u=-2\int x^2\mathrm{d}u=-2\int\frac{1}{(u^2+1)^2}\mathrm{d}u\tag{12.4.740}$$

So now we have to solve:

$$\int\frac{1}{(u^2+1)^2}\mathrm{d}u\tag{12.4.741}$$

But we recognize here the primitive of:

$$f(x)=\frac{1}{(1+x^2)^2}\tag{12.4.742}$$

That we have already proved in the section of Differential and Integral Calculus (see page 1549) and that lead us to:

$$F(x)=\int\frac{1}{(1+x^2)^2}\mathrm{d}x=\frac{1}{2}\left(\frac{x}{1+x^2}+\arctan(x)\right)\tag{12.4.743}$$

Therefore:

$$-2\int\frac{1}{(u^2+1)^2}\mathrm{d}u=-\arctan(u)-\frac{u}{u^2+1}\tag{12.4.744}$$

Undo substitution:

$$u=\sqrt{\frac{1}{x}-1}\tag{12.4.745}$$

We get:

$$-\arctan(u)-\frac{u}{u^2+1}=-\sqrt{\frac{1}{x}-1}x-\arctan\left(\sqrt{\frac{1}{x}-1}\right)\tag{12.4.746}$$

The problem is then solved:

$$\int\frac{1}{\sqrt{\frac{1}{x}-1}}\mathrm{d}x=-\sqrt{\frac{1}{x}-1}x-\arctan\left(\sqrt{\frac{1}{x}-1}\right)+c^{te}\tag{12.4.747}$$

Therefore (ignoring the constant):

$$\begin{aligned}t_s=\frac{1}{c}\int\limits_0^{R_S}\frac{1}{\sqrt{\frac{2GM}{c^2r}-1}}\mathrm{d}r&=\frac{1}{c}\left[-\sqrt{\frac{2GM}{c^2r}-1}\frac{c^2r}{2GM}-\frac{2GM}{c^2}\arctan\left(\sqrt{\frac{2GM}{c^2r}-1}\right)\right]\Bigg|_0^{R_s}\\&=\frac{1}{c}\left(-\underbrace{\sqrt{\frac{2GM}{c^2\cdot\frac{2GM}{c^2}}-1}\frac{c^2\cdot\frac{2GM}{c^2}}{2GM}}_{=0}-\underbrace{\frac{2GM}{c^2}\arctan\left(\sqrt{\frac{2GM}{c^2\cdot\frac{2GM}{c^2}}-1}\right)}_{=0}\right)\\&-\frac{1}{c}\left(-\sqrt{\frac{2GM}{c^2\cdot 0}-1}\frac{c^2\cdot 0}{2GM}-\frac{2GM}{c^2}\arctan\left(\sqrt{\frac{2GM}{c^2\cdot 0}-1}\right)\right)\end{aligned}\tag{12.4.748}$$

But for the second parentheses we see we should better take the limit. Then we have:

$$\begin{gathered}\lim_{r\longrightarrow 0^+}\sqrt{\frac{2GM}{c^2r}-1}\frac{c^2r}{2GM}=0\\\lim_{r\longrightarrow 0^+}\arctan\left(\sqrt{\frac{2GM}{c^2r}-1}\right)=\frac{\pi}{2}\end{gathered}\tag{12.4.749}$$

Therefore:

$$t_s=-\frac{1}{c}\left(0-\frac{2GM}{c^2}\frac{\pi}{2}\right)=\frac{\pi GM}{c^3}\tag{12.4.750}$$

Before the 11970s (holocene calendar), most physicists believed that the interior of a Schwarzschild black hole curved inwards towards a sharp point at the singularity. However, in the late 11960s (holocene calendar), Soviet physicists Vladimir Belinskii, Isaak Khalatnikov, and Evgeny Lifshitz discovered that this model was only true when the space-time inside the black hole had not been perturbed. Any perturbations, such as those caused by matter or radiation falling in, would cause space to oscillate chaotically near the singularity according to a metric named the "Mixmaster dynamics". Any matter falling in would experience intense tidal forces rapidly changing in direction, all while being compressed into an increasingly small volume.

Remark

Black Hole research has indirectly contributed to modern Wi-Fi technology through advancements in signal processing. In the 11990s (holocene calendar), physicist John O'Sullivan was working on detecting radio signals from mini Black Holes predicted by Stephen Hawking. To filter out noise and interference, he developed a method using fast Fourier transforms to analyze and recombine signals. This technique later proved useful in solving issues with radio wave communication between computers, such as interference from reflected signals. O'Sullivan's work laid the foundation for the technology used in Wi-Fi systems today.

12.4.6.6.1.4 Black Hole Flamm's paraboloid representation

The spatial curvature of the Schwarzschild solution for $r > r_\text{s}$ can be visualized in a famous pseudo-3D representation named "Flamm's paraboloid".

For this purpose, let us consider a constant time equatorial slice through the Schwarzschild solution given for reminder by:

$$\mathrm{d}s^2 = \left(1 - \frac{2GM}{c^2 r}\right) c^2 \mathrm{d}t^2 - \frac{1}{\left(1 - \frac{2GM}{c^2 r}\right)} \mathrm{d}r^2 - r^2 \left(\mathrm{d}\theta^2 + \sin^2(\theta)\mathrm{d}\phi^2\right) \tag{12.4.751}$$

by fixing $\theta = \pi/2, t = c^{te}$, and letting the remaining Schwarzschild coordinates (r, ϕ) vary the latter reduces to:

$$\mathrm{d}s^2 = -\frac{1}{\left(1 - \frac{2GM}{c^2 r}\right)} \mathrm{d}r^2 - r^2 \mathrm{d}\phi^2 \tag{12.4.752}$$

Rearranging:

$$-\mathrm{d}s^2 = \frac{1}{\left(1 - \frac{2GM}{c^2 r}\right)} \mathrm{d}r^2 + r^2 \mathrm{d}\phi^2 \tag{12.4.753}$$

This done, Flamm's paraboloid may be derived as follows:

The Euclidean metric in the cylindrical coordinates (r, ϕ, w) is written for reminder by:

$$-\mathrm{d}s^2 = \mathrm{d}w^2 + \mathrm{d}r^2 + r^2 \mathrm{d}\phi^2 \tag{12.4.754}$$

Letting the surface be described by the function $w = w(r)$, the Euclidean metric can be written as (see page 5729):

$$-\mathrm{d}s^2 = \left(1 + \left(\frac{\mathrm{d}w}{\mathrm{d}r}\right)^2\right) \mathrm{d}r^2 + r^2 \mathrm{d}\phi^2 \tag{12.4.755}$$

Comparing this with the Schwarzschild metric in the equatorial plane $(\theta = \pi/2)$ at a fixed time $(t = c^{te}, \mathrm{d}t = 0)$:

$$-\mathrm{d}s^2 = \left(1 - \frac{r_\text{s}}{r}\right)^{-1} \mathrm{d}r^2 + r^2 \mathrm{d}\phi^2 \tag{12.4.756}$$

yields an integral expression for $w(r)$:

$$w(r) = \int \frac{\mathrm{d}r}{\sqrt{\frac{r}{r_\text{s}} - 1}} = 2r_\text{s}\sqrt{\frac{r}{r_\text{s}} - 1} + c^{te} = 2\sqrt{r_s(r - r_S)} + c^{te} \tag{12.4.757}$$

whose solution is Flamm's paraboloid.

We can plot this solution typically with pstplots in LaTeX. This gives:

$$\begin{cases} x = r\cos(u) \\ y = r\sin(u) \\ z = 2\sqrt{r_S(r - r_S)} \end{cases}$$

Figure 12.243: **Schwarzschild black hole representation based on Flamm's paraboloid**

12.4.6.6.1.5 White Hole

In General Relativity, a "White hole" is a hypothetical region of space-time and singularity that cannot be entered from the outside, although energy, matter, light and information can escape from it. In this sense, it is the opposite of a black hole, from which energy, matter, light and information cannot escape.

The basic reason why White Holes show up in General Relativity theory is because Einstein's equations are time-reversible, but when something falls into a Black Hole, it never re-emerges. We solve this paradox by realizing that the time-reversed path of something falling into a Black Hole in the future is that object emerging from a White Hole in the past.

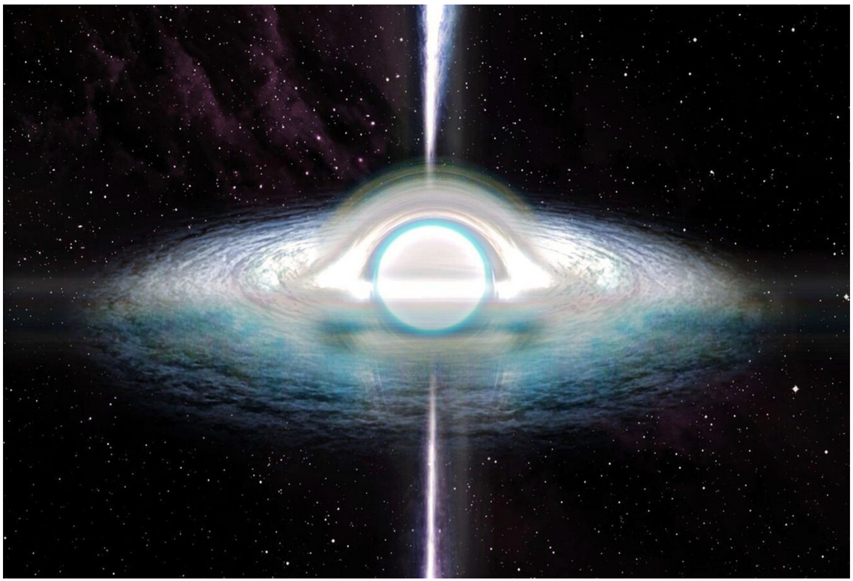

Figure 12.244: Artist's impression of a white hole (source: Wikipedia, author: Baperookamo)

A White Hole's color is a subject of speculation, but it would likely appear as a fiercely bright, luminous sphere of light because it expels matter and light, unlike a Black Hole. However, if the source of the material it expels does not produce light, it could also appear black. The name "White Hole" is just a mathematical counterpart to a Black Hole, not a literal color descriptor.

12.4.6.7 Gravitational waves

Before we focus on the maths, let us do a simple introduction.

"Gravitational waves" are ripples in the curvature of space-time that propagate as waves at the speed of light, generated in certain gravitational interactions that propagate outward from their source. The possibility of gravitational waves was discussed in 11893 (holocene calendar) by Oliver Heaviside using the analogy between the inverse-square law in gravitation and electricity. In 11905 (holocene calendar) Henri Poincaré first proposed gravitational waves emanating from a body and propagating at the speed of light as being required by the Lorentz transformations. Predicted in 11916 (holocene calendar) by Albert Einstein on the basis of his theory of General Relativity, gravitational waves transport energy as gravitational radiation, a form of radiant energy similar to electromagnetic radiation. Gravitational waves cannot exist in the Newton's law of universal gravitation, since that law is predicated on the assumption that physical interactions propagate at infinite speed.

Gravitational-wave astronomy is an emerging branch of observational astronomy which aims to use gravitational waves to collect observational data about sources of detectable gravitational waves such as binary star systems composed of White Dwarfs, neutron stars, and Black Holes; and events such as supernovae, and the formation of the early universe shortly after the Big Bang (i.e. starting point of the expansion of our universe).

On February 11, 12016 (holocene calendar), the LIGO Scientific Collaboration and Virgo Collaboration teams announced that they had made the first observation of gravitational waves, originating from a pair of merging Black Holes using the Advanced LIGO detectors. On June 15, 2016 (holocene calendar), a second detection of gravitational waves from coalescing Black Holes was announced. Besides LIGO, many other gravitational-wave observatories (detectors) are under construction.

Remark

The reader must remember that Newtonian gravity is not local, this bothered Newton a lot back then! You see if you take Newton's law of gravity, with the gravitational force proportional to the mass divided by the square of the distance, then if you move the mass, the distance increases and the force changes instantaneously, everywhere. Newton was greatly bothered by this. He named it "action at a distance" and that's also what Einstein meant by the phrase. Einstein's theory of General Relativity, which we use now to describe gravity, doesn't have this problem. In Einstein's theory, gravity is described by the curvature of space and time. And that curvature is caused by the mass and energy in space-time. If you move the mass that causes space-time to curve, then the curvature changes, but not instantaneously. The change spreads outwards at the speed of light as we will prove it below. So, Einstein's theory is "local" as physicists say.

In real life it looks like this (in the legend of the photo below, the year is given according to the holocene calendar):

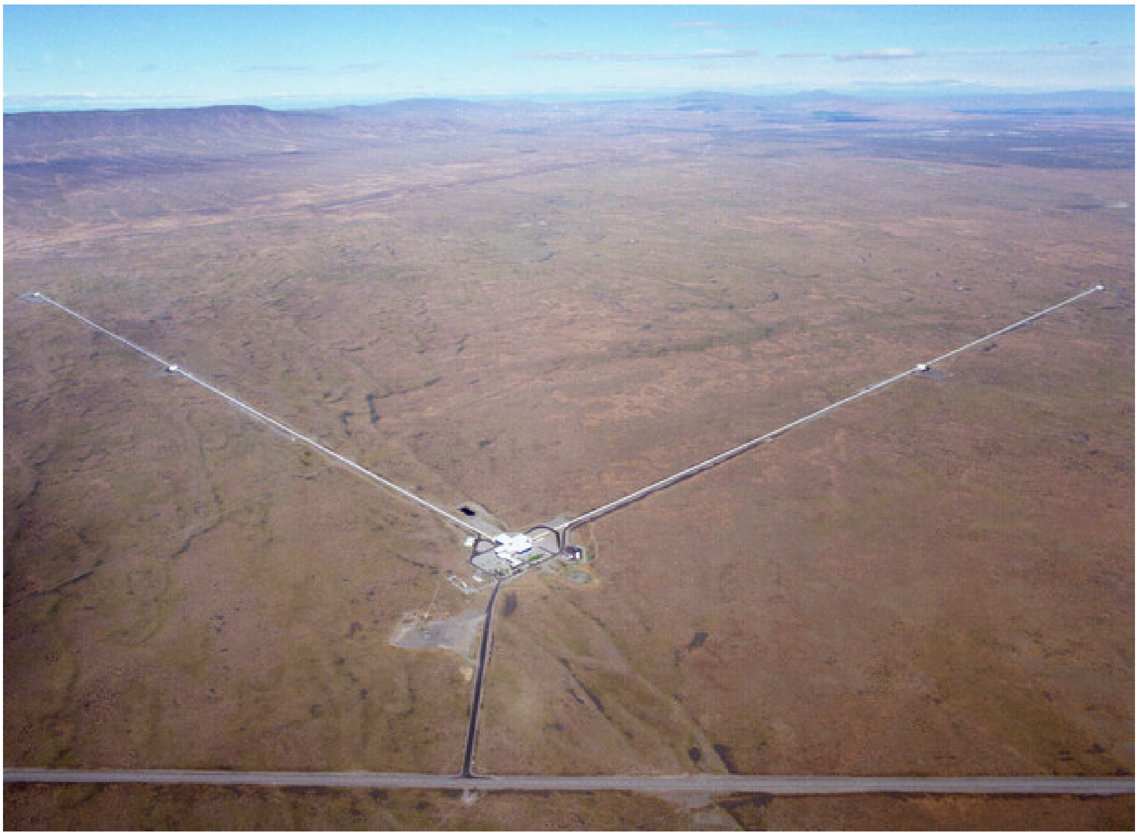

Figure 12.246: **Hanford LIGO detector - October 30, 12000 - Washington state (source: LIGO)**

The most typical illustration that we can see of gravitational waves in newspapers are those generated by the special case of a high speed dynamic gravitation field due to the rotation of two massive object around each other. Otherwise, and it is obvious, a collapsing star at the end of its life also generated a variational gravitational field but that is quite difficult to detect with actual existing instruments as a star alone is not massive enough to generate detectable gravitation waves:

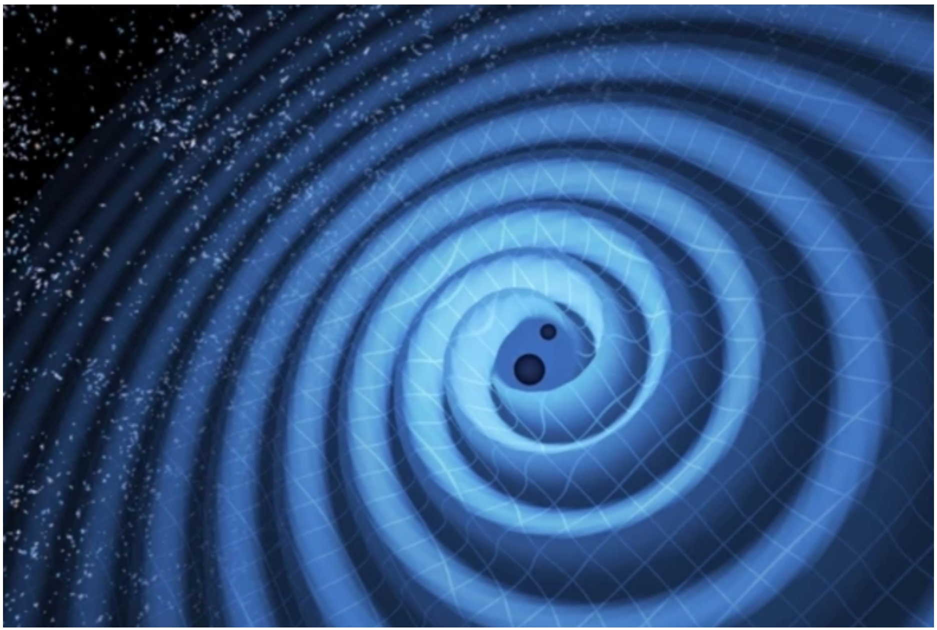

Figure 12.247: **Pseudo-3D (wrong) common visualization of gravitational wave of a binary system**

But obviously gravitational waves don't make things go up and down like ocean waves as illustrated above, and they're definitely not like that planet on a trampoline — after all, there's nothing "below" to pull things downward so there can't be a dent. And gravitational waves don't do spirals, much...

In a gravitational wave, space itself is compressed and stretched. A particle caught in a gravitational wave doesn't get pushed back and forth. Instead, it shrinks and expands in place. If you encounter a gravitational wave, you and all your calibrated measurement gear (yardsticks, digital rangers, that slide rule you're so proud of) shrink and expand together. You would only notice the experience if you happened to be comparing two extremely precise LASER rangers set perpendicular to each other (LIGO!). One would briefly register a slight change compared to the other one.

Now let us deal with the maths. As almost always in science there are multiple ways to introduce a new tool. In this textbook, as most of times, we will use what we consider the most easy one and that is "physicist" or "engineer" oriented...

So first, remember that earlier we have proved under some assumptions that:

$$\nabla^2 h_{00}=\Delta h_{00}=-\frac{8\pi G}{c^4}T_{00} \tag{12.4.758}$$

That what we have seen afterwards can be written more generally as:

$$\nabla^2 h_{\mu\nu}=\Delta h_{\mu\nu}=-\frac{8\pi G}{c^4}T_{\mu\nu} \tag{12.4.759}$$

If we explicit it by keeping in mind Classical Mechanics it would be written in 3D:

$$\frac{\partial^2 h_{\mu\nu}}{\partial x^2}+\frac{\partial^2 h_{\mu\nu}}{\partial y^2}+\frac{\partial^2 h_{\mu\nu}}{\partial z^2}=-\frac{8\pi G}{c^4}T_{\mu\nu} \tag{12.4.760}$$

or a bit better:

$$\frac{\partial^2 h_{\mu\nu}}{\partial {x^1}^2}+\frac{\partial^2 h_{\mu\nu}}{\partial {x^2}^2}+\frac{\partial^2 h_{\mu\nu}}{\partial {x^3}^2}=-\frac{8\pi G}{c^4}T_{\mu\nu} \tag{12.4.761}$$

But... but...! We are in General Relativity and we have to introduce the 4-th dimensions:

$$\frac{\partial^2 h_{\mu\nu}}{\partial {x^0}^2}+\frac{\partial^2 h_{\mu\nu}}{\partial {x^1}^2}+\frac{\partial^2}{\partial {x^2}^2}+\frac{\partial^2 h_{\mu\nu}}{\partial {x^3}^2}=-\frac{8\pi G}{c^4}T_{\mu\nu} \tag{12.4.762}$$

This is better but now let us explicit this using in cartesian coordinates using the metric $(-,+,+,+)$. We then get:

$$\frac{\partial^2 h_{\mu\nu}}{\partial(-ct)^2}+\frac{\partial^2}{\partial x^2}+\frac{\partial^h_{\mu\nu}2}{\partial y^2}+\frac{\partial^2 h_{\mu\nu}}{\partial z^2}=-\frac{8\pi G}{c^4}T_{\mu\nu} \tag{12.4.763}$$

Assuming that we a observing a piece (volume) of space where there is no matter and no radiation in any form, then $T_{\mu\nu}=0$ and we get:

$$-\frac{1}{c^2}\frac{\partial^2 h_{\mu\nu}}{\partial t^2}+\frac{\partial^2 h_{\mu\nu}}{\partial x^2}+\frac{\partial^2 h_{\mu\nu}}{\partial y^2}+\frac{\partial^2 h_{\mu\nu}}{\partial z^2}=0 \tag{12.4.764}$$

Using the d'Alembertian already introduced in the section of Electrodynamics but now in its General Relativity form named "flat-space d'Alembertian":

$$\Box=\partial^{\mu}\partial_{\mu}=g^{\mu\nu}\partial_{\nu}\partial_{\mu}=\eta^{\mu\nu}\partial_{\nu}\partial_{\mu}=-\frac{1}{c^2}\partial_t^2+\Delta \tag{12.4.765}$$

that latter relation is commonly written in textbooks:

$$\boxed{\Box h_{\mu\nu}=0} \tag{12.4.766}$$

Taking back and rearranging the explicit relation we get (we see that this equation also gives us that space transmits gravitational waves at the speed of light as confirmed experimentally as reported in [3]!):

$$\boxed{\frac{\partial^2 h_{\mu\nu}}{\partial x^2}+\frac{\partial^2 h_{\mu\nu}}{\partial y^2}+\frac{\partial^2 h_{\mu\nu}}{\partial z^2}=\frac{1}{c^2}\frac{\partial^2 h_{\mu\nu}}{\partial t^2}} \tag{12.4.767}$$

and named the "gravitational wave equation", "gravitational propagation equation" or "gravitational d'Alembert's equation".

We know that a simple solution to:

$$\left(\nabla^2-\frac{1}{c^2}\frac{\partial^2}{\partial t^2}\right)h_{\mu\nu}=0 \tag{12.4.768}$$

can typically be:

$$\bar{h}_{\mu\nu}=\Re\left(\hat{A}_{\mu\nu}e^{\mathrm{i}k_{\rho}x^{\rho}}\right) \tag{12.4.769}$$

The amplitude $\hat{A}_{\mu\nu}$ and the wave vector k_{ρ} must satisfy the differential equation, therefore:

$$k_{\rho}=0 \tag{12.4.770}$$

Gravitational waves pass through boundaries that light cannot! They can transport information about what happens inside the event horizons of Black Holes, and they can pass through the cosmic background (CMB) radiation (see section Cosmogony page 5966), the barrier of light that prevent us from seeing our Universe before it turned $380,000$ years old!

Remark

A common question about this topic is: *How can gravity escape out of a Black Hole when it is known that even light cannot escape a Black Hole?*. The answer is quite simple! Gravity does not escape the Black hole, it covers the Black Hole event horizon like a blanket (all the information of remaining stuff collapsing as a Black Hole is on the surface of Event Horizon for theoretically a huge amount of time), pulling stuff towards itself and the singularity.

So for summary General Relativity has successfully with high accuracy pass the following experimental tests in order of verification (top oldest):

1. Mercury perihelion precession
2. Light deviation
3. Black Holes
4. Universe expansion
5. Time Dilatation
6. Gravitational waves

Let us point out once again a very important point. Before Albert Einstein, geometry was considered an integral part of the laws. Albert Einstein has shown that the geometry of space evolves in time according to other, even deeper, laws. It is important to understand this point. The geometry of space is not part of the laws of nature (this was criticized at his time by many French physicists). Therefore, nothing that we can find in these laws tells us what geometry of space we are working in. Thus, before we begin to solve the equations of Einstein's General Relativity, we have absolutely no idea what geometry we ear dealing with. We only discover it once the equations are solved!

In extenso, the choice of 4 dimensions is part of the background. Could it be possible that another deeper theory does not require presupposing the number of dimensions?

To sum up, the idea of independence relatively to the background, in its most general formulation, is a wise way of making physics: made up of better theories, in which the things which before were postulated, will be explained in allowing such things to evolve over time according to new laws.

This is also a difficulty of Quantum Theory, that latter is essentially background dependent at the opposite of General Relativity that is "background independent".

Experimental Verification of General Relativity

General Relativity (GR) has been tested in a wide range of regimes, from the Solar System to binary black holes. Below is a summary of key experimental confirmations.

TEST		WHAT WAS TESTED	PEER-REVIEW PAPER (DOI)
	1. Advance of the perihelion of Mercury	The observed precession of Mercury's perihelion (≈ 43 arcsec/century) matches GR's prediction, unaccounted for by Newtonian gravity and perturbations from other planets.	Bertrand Berche and Ernesto Medina, "The advance of Mercury's perihelion" Eur. J. Phys. **45**, 025603 (2024). doi:10.1088/1361-6404/ad1b7a
	2. Deflection of light by the Sun	Starlight passing near the Sun is deflected by an amount consistent with GR. Measured during solar eclipses.	C. W. F. Everitt et al., "Deflection of Light by the Sun: Measurement of the Relativistic Deflection of Light" Phys. Rev. Lett. **106**, 221101 (2011). doi:10.1103/PhysRevLett.106.221101
	3. Shapiro time delay	Radar signals passing near a massive body (e.g., the Sun) experience an extra time delay, as predicted by GR.	Bertotti, Iess & Tortora, "A test of general relativity using radio links with the Cassini spacecraft" Nature **425**, 374–376 (2003). doi:10.1038/nature01997
	4. Geodetic (de Sitter) precession	The spin axis of a gyroscope in Earth orbit (Gravity Probe B) precesses due to spacetime curvature, in agreement with GR.	I. I. Shapiro et al. (Gravity Probe B Collaboration), "Measurement of the Geodetic Precession of a Gyroscope in Earth Orbit" Phys. Rev. Lett. **103**, 211101 (2009). doi:10.1103/PhysRevLett.103.211101
	5. Frame-dragging (Lense–Thirring effect)	Earth's rotation drags spacetime, causing a small precession of satellite orbits (measured by LAGEOS and LAGEOS II), consistent with GR.	M. Ciufolini et al., "A test of general relativity using the LAGEOS satellites and a laser ranging network" Science **279**, 2100–2103 (1998). doi:10.1126/science.279.5359.2100
	6. Hulse–Taylor binary pulsar	The orbital decay of the binary pulsar PSR **B1913+16**, due to gravitational wave emission, matches GR's prediction with high precision.	J. H. Taylor & J. M. Weisberg, "A new test of general relativity – Gravitational radiation and the binary pulsar PSR 1913+16" Astrophys. J. **253**, 908–920 (1982). doi:10.1086/159690
	7. Gravitational waves from binary black hole mergers (GW150914 and others)	The waveform of GWs from binary black hole mergers matches GR predictions across inspiral, merger and ringdown.	B. P. Abbott et al. (LIGO Scientific Collaboration and Virgo Collaboration), "Observation of Gravitational Waves from a Binary Black Hole Merger" Phys. Rev. Lett. **116**, 061102 (2016). doi:10.1103/PhysRevLett.116.061102
	8. Black hole shadow (M87*)	The size and shape of the shadow of M87* measured by the Event Horizon Telescope are consistent with GR predictions for a black hole.	K. Akiyama et al. (Event Horizon Telescope Collaboration), "First M87 Event Horizon Telescope Results. I. The Shadow of the Supermassive Black Hole" Astrophys. J. Lett. **875**, L1 (2019). doi:10.3847/2041-8213/ab0ec7
	9. Gravitational redshift of star S2 near Sgr A*	The combined gravitational redshift and transverse Doppler effect of star S2 measured near pericentre agree with GR.	GRAVITY Collaboration, "Detection of the gravitational redshift in the orbit of the star S2 near the Galactic centre massive black hole" Astron. Astrophys. **615**, L15 (2018). doi:10.1051/0004-6361/201832718
	10. Black hole spectroscopy (GW250114)	Quasinormal mode frequencies measured in the ringdown of the black hole merger GW250114 match the GR (Kerr) predictions.	A. G. Abac et al. (LIGO-Virgo-KAGRA Collaborations), "Black Hole Spectroscopy and Tests of General Relativity with GW250114" Phys. Rev. Lett. **136**, 041403 (2026). doi:10.1103/6c61-fm1n

Note: The list is not exhaustive. GR has been further tested in many additional experiments and astrophysical observations.

Figure 12.249: **Summary of the most well-known experimental tests of General Relativity**

12.4.7 Einstein-Hilbert action

The "Einstein-Hilbert action" (also referred to as "Hilbert action") in General Relativity is the action that yields the Einstein field equations through the principle of least action (see section Analytical Mechanics page 3131). With the $(-+++)$ metric signature, the gravitational part of the action is given as:

$$S=-\frac{1}{c\kappa}\int R\sqrt{|g|}\mathrm{d}^4x=-\frac{c^3}{8\pi G}\int R\sqrt{|g|}\mathrm{d}^4x \tag{12.4.771}$$

The derivation of equations from an action has several advantages. First of all, it allows for easy unification of General Relativity with other classical field theories (such as Maxwell theory), which are also formulated in terms of an action (this is especially why we were obliged to introduced this action in this textbook!).

There are multiple ways to make the proof of that action, but we will use the one that is the easiest in our point of view and that is more "engineer way of life" oriented rather than "theoretical physicist way of life"... So let's go!

Proof 12.0.1. We know that the classical action in mechanics is given for recall by:

$$S=\int\limits_{t_1}^{t_2} L\mathrm{d}t \tag{12.4.772}$$

In this expression, the Lagrangian L is homogeneous to an energy. In gravitation as in electromagnetism, the energy-stress tensor T is homogeneous to a density energy $\mathcal{L}$, which obliges us to introduce this density in the action by integrating on the volume as following:

$$S=\int\limits_{t_1}^{t_2}\left[\int\limits_V \mathcal{L}\mathrm{d}V\right]\mathrm{d}t=\int \mathcal{L}\mathrm{d}\Omega \tag{12.4.773}$$

The search of an action invariant by change of reference frame imposes us an element of volume $\mathrm{d}\Omega$ quadridimensional that is also invariant by change of reference frame. And we have proved in the section of Tensor Calculus that such an element was given by the Riemmanian volume (see section Tensor Calculus page 2058):

$$\mathrm{d}\Omega=\sqrt{|g|}\mathrm{d}x^4 \tag{12.4.774}$$

Then we deduce the new form of the action:

$$S=\int \mathcal{L}\sqrt{|g|}\mathrm{d}x^4 \tag{12.4.775}$$

But as we look the units, as $x^0=ct$ the units are not homogeneous to an energy anymore. Then we must divide by c:

$$S=\frac{1}{c}\int \mathcal{L}\sqrt{|g|}\mathrm{d}x^4 \tag{12.4.776}$$

Now we need to find a scalar for R that is invariant has for units a density of energy. For this, let us recall that during our proof of the Einstein's field equations earlier above (page 5766), we get the relation:

$$R-2R=\kappa g^{\rho\sigma}T_{\rho\sigma} \tag{12.4.777}$$

That obviously can be simplified as:

$$R=-\kappa g^{\rho\sigma}T_{\rho\sigma} \tag{12.4.778}$$

and as $g^{\rho\sigma}T_{\rho\sigma}$ is often denoted simply T, we get:

$$R=-\kappa T=-\frac{8\pi G}{c^4}T \tag{12.4.779}$$

And as the left term is a well known scalar implicitly involving g^{ij} (as for recall $R=g^{ij}R_{ij}$), what may be quite useful intuitively, it is a good candidate! However...:

- It doesn't have the units of a density energy
- It seems to be negative as T is positive (at least as far as we know...)

Then if we write:

$$-\frac{R}{\kappa}=T \tag{12.4.780}$$

We get a very good candidate four our Lagrangian density. Then we will try with:

$$\boxed{S=-\frac{1}{\kappa c}\int R\sqrt{|g|}\mathrm{d}x^4=-\frac{1}{\kappa c}\int(g^{ij}R_{ij})\sqrt{|g|}\mathrm{d}x^4} \tag{12.4.781}$$

■ Q.E.D.

Ok the derivation is quite based on trial and errors reasoning. So it may be a good practice to check if this action lead us back to the Einstein Field questions (or something similar) by applying the variational principle!

Assuming that all conditions are satisfied to the variation to pass through the integral, we have:

$$\delta S=-\frac{1}{\kappa c}\int\delta\left(g^{ij}R_{ij}\sqrt{|g|}\right)\mathrm{d}x^4 \tag{12.4.782}$$

As the determinant $|g|$ of the g_{ij} is negative, at least in the most common cases (Minkowski, Schwarzschild, Robertson-Walker, Kerr, etc.), we write:

$$\delta\left(g^{ij}R_{ij}\sqrt{|g|}\right)=\delta\left(g^{ij}R_{ij}\sqrt{-g}\right) \tag{12.4.783}$$

This expression is differentiate as the product of three term:

$$\delta\left(g^{ij}R_{ij}\sqrt{-g}\right)=\delta(g^{ij})R_{ij}\sqrt{-g}+\delta(R_{ij})g^{ij}\sqrt{-g}+\delta(\sqrt{-g})g^{ij}R_{ij} \tag{12.4.784}$$

That can be written:

$$\delta\left(g^{ij}R_{ij}\sqrt{-g}\right)=\delta(g^{ij})R_{ij}\sqrt{-g}+\delta(R_{ij})g^{ij}\sqrt{-g}+\delta(\sqrt{-g})R \tag{12.4.785}$$

The non-obvious idea is to make appear δg^{ij} as a factor in the integral of the variation δS and we will request as always that $\delta S=0$ and conclude/check if the result we get is interesting or not!?

In the differential above the first term $\delta(g^{ij})R_{ij}\sqrt{-g}$ naturally makes appear $\delta(g^{ij})$, and therefore doesn't need any treatment.

For the other two terms instead, we will have to express $\delta(R_{ij})$ and $\delta(\sqrt{-g})$ in function of the $\delta(g_{ij})$, or show that their contribution is equal to zero. It is not an easy work, it needed a great mathematician like David Hilbert to achieve this work. So here is the procedure that as you will see... is quit a pain in the a**...

- First we focus on the term $\sqrt{-g}$. For this let us consider a matrix with the following form:

  $$A=\begin{bmatrix}a_0 & 0\\ 0 & a_1\end{bmatrix} \tag{12.4.786}$$

  The trace of this matrix, as for any matrix, is the sum of the elements of the main diagonal, so:

  $$\text{tr}(A)=\text{tr}(A)=a_0+a_1 \tag{12.4.787}$$

  So that:

  $$e^{\text{tr}(A)}=e^{a_0+a_1} \tag{12.4.788}$$

  If we consider the exponential matrix e^A (see section Linear Algebra page 1628) as:

  $$e^A=\begin{bmatrix}e^{a_0} & 0\\ 0 & e^{a_1}\end{bmatrix} \tag{12.4.789}$$

  Then the determinant of this diagonal matrix is (see section Linear Algebra page 1966):

  $$\det(e^A)=e^{a_0}e^{a_1}=e^{a_0+a_1} \tag{12.4.790}$$

  So that finally we can write:

  $$\det(e^A)=e^{\text{tr}(A)} \tag{12.4.791}$$

  If we put $B=e^A$, we have obviously:

  $$e^A=B\Rightarrow \ln(e^A)=\ln(B)\Rightarrow A=\ln(B) \tag{12.4.792}$$

  So as $\det(e^A)=e^{\text{tr}(A)}$, we have:

  $$\det(B)=e^{\text{tr}(\ln(B))} \tag{12.4.793}$$

  Therefore:

  $$\ln\left(\det(B)\right)=\ln\left(e^{\text{tr}(\ln(B))}\right) \tag{12.4.794}$$

Hence:

$$\ln\left(\det(B)\right)=\operatorname{tr}(\ln(B)) \tag{12.4.795}$$

Taking the differential of both side:

$$\mathrm{d}\ln\left(\det(B)\right)=\mathrm{d}(\operatorname{tr}(\ln(B)))\Rightarrow\frac{1}{\det(B)}\mathrm{d}(\det(B))=\operatorname{tr}\left(\frac{1}{B}\mathrm{d}B\right) \tag{12.4.796}$$

Or written in a more condensed way:

$$\frac{\mathrm{d}(\det(B))}{\det(B)}=\operatorname{tr}\left(\frac{\mathrm{d}B}{B}\right)=\operatorname{tr}(B^{-1}\mathrm{d}B) \tag{12.4.797}$$

If we now relate this last result to the metric g_{ij}, we set $B=g_{ij}$, $B^{-1}=g^{ij}$ and $\det(B)=g$ leading to:

$$\frac{\mathrm{d}g}{g}=g^{ij}\mathrm{d}g_{ij} \tag{12.4.798}$$

Or written in the physics way:

$$\frac{\delta g}{g}=g^{ij}\delta g_{ij} \tag{12.4.799}$$

and rearranged a bit:

$$\delta g=gg^{ij}\delta g_{ij} \tag{12.4.800}$$

Now let us take the differential of $\sqrt{-g}$ (or in other words, the "variational of the metric determinant"):

$$\delta\sqrt{-g}=-\frac{1}{2\sqrt{-g}}\delta g \tag{12.4.801}$$

and injecting the prior-previous relation:

$$\delta\sqrt{-g}=-\frac{1}{2\sqrt{-g}}\left(gg^{ij}\delta g_{ij}\right)=\frac{1}{2\sqrt{-g}}(-g)g^{ij}\delta g_{ij}=\frac{1}{2\sqrt{-g}}(\sqrt{-g})^2g^{ij}\delta g_{ij}=\frac{1}{2}\sqrt{-g}g^{ij}\delta g_{ij} \tag{12.4.802}$$

We can still write this relation in a slightly different style! We know that the metric and its inverse are related in the following way (see section Tensor Calculus page 2051):

$$g_{ij}g^{ij}=\delta_i^i \tag{12.4.803}$$

which leads to:

$$\delta(g_{ij}g^{ij})=\delta(\delta_i^i)=0 \tag{12.4.804}$$

Therefore:

$$\delta(g_{ij}g^{ij})=\delta g_{ij}g^{ij}+g_{ij}\delta g^{ij}=0 \tag{12.4.805}$$

Hence:

$$\delta g_{ij}g^{ij}=-g_{ij}\delta g^{ij} \tag{12.4.806}$$

Finally we can write:

$$\delta\sqrt{-g}=-\frac{1}{2}\sqrt{-g}g_{ij}\delta g^{ij} \tag{12.4.807}$$

And this is the first result we were looking for that we will keep for later to re-inject in the action integral variational δS.

- Now we focus on the term $\delta(R_{ij})$. For this, let us recall (see section Tensor Calculus page 2127):

$$R_{\mu\mu}=R^{\alpha}_{\mu\alpha\nu}=\partial_{\alpha}\Gamma^{\alpha}_{\mu\nu}-\partial_{\nu}\Gamma^{\alpha}_{\mu\alpha}+\Gamma^{\alpha}_{\sigma\gamma}\Gamma^{\gamma}_{\mu\nu}-\Gamma^{\alpha}_{\nu\gamma}\Gamma^{\gamma}_{\mu\sigma} \tag{12.4.808}$$

Then varying it, gives:

$$\delta R_{\mu\nu}=\partial_{\alpha}\delta\Gamma^{\alpha}_{\mu\nu}-\partial_{\nu}\delta\Gamma^{\alpha}_{\mu\alpha}+\delta\Gamma^{\alpha}_{\alpha\gamma}\Gamma^{\gamma}_{\mu\nu}+\Gamma^{\alpha}_{\alpha\gamma}\delta\Gamma^{\gamma}_{\mu\nu}-\delta\Gamma^{\alpha}_{\nu\gamma}\Gamma^{\gamma}_{\mu\alpha}-\Gamma^{\alpha}_{\nu\gamma}\delta\Gamma^{\gamma}_{\mu\alpha} \tag{12.4.809}$$

The first two terms of this expression suggest that it could be the difference between two covariant derivatives. Let us prove that it is the case.

We have by applying the definition of the second order covariant derivative[53]:

$$\begin{aligned}\nabla_{\alpha}(\delta\Gamma^{\alpha}_{\mu\nu})&=\partial_{\alpha}\delta\Gamma^{\alpha}_{\mu\nu}+\Gamma^{\alpha}_{\alpha\gamma}\delta\Gamma^{\gamma}_{\mu\nu}-\delta\Gamma^{\alpha}_{\nu\gamma}\Gamma^{\gamma}_{\mu\alpha}-\delta\Gamma^{\alpha}_{\mu\gamma}\Gamma^{\gamma}_{\nu\alpha}\nabla_{\alpha}(\delta\Gamma^{\alpha}_{\mu\alpha})\\&=\partial_{\nu}\delta\Gamma^{\alpha}_{\mu\alpha}+\delta\Gamma^{\gamma}_{\mu\alpha}\Gamma^{\alpha}_{\nu\gamma}-\delta\Gamma^{\alpha}_{\alpha\gamma}\Gamma^{\gamma}_{\mu\nu}-\delta\Gamma^{\alpha}_{\mu\gamma}\Gamma^{\gamma}_{\nu\alpha}\end{aligned} \tag{12.4.810}$$

We cans thus verify that:

$$\begin{aligned}\nabla_{\alpha}(\delta\Gamma^{\alpha}_{\mu\nu})-\nabla_{\alpha}(\delta\Gamma^{\alpha}_{\mu\alpha})&=\partial_{\alpha}\delta\Gamma^{\alpha}_{\mu\nu}+\Gamma^{\alpha}_{\alpha\gamma}\delta\Gamma^{\gamma}_{\mu\nu}-\delta\Gamma^{\alpha}_{\nu\gamma}\Gamma^{\gamma}_{\mu\alpha}-\cancel{\delta\Gamma^{\alpha}_{\mu\gamma}\Gamma^{\gamma}_{\nu\alpha}}\\&-\left(\partial_{\nu}\delta\Gamma^{\alpha}_{\mu\alpha}+\delta\Gamma^{\gamma}_{\mu\alpha}\Gamma^{\alpha}_{\nu\gamma}-\delta\Gamma^{\alpha}_{\alpha\gamma}\Gamma^{\gamma}_{\mu\nu}-\cancel{\delta\Gamma^{\alpha}_{\mu\gamma}\Gamma^{\gamma}_{\nu\alpha}}\right)\\&=\delta R_{\mu\nu}\end{aligned} \tag{12.4.811}$$

The relation:

$$\boxed{\nabla_{\alpha}(\delta\Gamma^{\alpha}_{\mu\nu})-\nabla_{\alpha}(\delta\Gamma^{\alpha}_{\mu\alpha})=\delta R_{\mu\nu}} \tag{12.4.812}$$

is named the "Palatini identity".

Now we can rewrite the action:

$$\begin{aligned}\delta S&=-\frac{1}{\kappa c}\int\left(\delta(g^{ij})R_{ij}\sqrt{-g}+\delta(R_{ij})g^{ij}\sqrt{-g}+\delta(\sqrt{-g})R\right)\mathrm{d}x^4\\&=-\frac{1}{\kappa c}\int\left[\delta g^{ij}R_{ij}\sqrt{-g}+\left(\nabla_{\alpha}(\delta\Gamma^{\alpha}_{\mu\nu})-\nabla_{\alpha}(\delta\Gamma^{\alpha}_{\mu\alpha})\right)g^{\mu\nu}\sqrt{-g}-\frac{1}{2}\sqrt{-g}g_{ij}\delta g^{ij}R\right]\mathrm{d}x^4\end{aligned} \tag{12.4.813}$$

---

[53] The Christoffel coefficients are not tensors, but their variations have the character of a tensor.

Let us focus on the term (we will use the property that the covariant derivative of the metric is equal to zero a proven in the section of Tensor Calculus):

$$\begin{aligned}\int g^{\mu\nu}\delta R_{\mu\nu}\sqrt{-g}\mathrm{d}^4x&=\int\left(\nabla_\alpha(\delta\Gamma^\alpha_{\mu\nu})-\nabla_\alpha(\delta\Gamma^\alpha_{\mu\alpha})\right)g^{\mu\nu}\sqrt{-g}\mathrm{d}^4x\\&=\int\left[\nabla_\alpha(g^{\mu\nu}\delta\Gamma^\alpha_{\mu\nu})-\nabla_\nu(g^{\mu\nu}\delta\Gamma^\alpha_{\mu\alpha})\right]\sqrt{-g}\mathrm{d}^4x\\&=\int\left[\nabla_\alpha(g^{\mu\nu}\delta\Gamma^\alpha_{\mu\nu})-\nabla_\alpha(g^{\mu\alpha}\delta\Gamma^\nu_{\mu\nu})\right]\sqrt{-g}\mathrm{d}^4x\\&=\int\nabla_\alpha\left(g^{\mu\nu}\delta\Gamma^\alpha_{\mu\nu}-g^{\mu\alpha}\delta\Gamma^\nu_{\mu\nu}\right)\sqrt{-g}\mathrm{d}^4x\end{aligned}\quad(12.4.814)$$

When considering the expression in brackets, we notice that the μ and ν indices cancel out, so that we are left with a tensor rank 1 tensor (very not obvious!):

$$g^{\mu\nu}\delta\Gamma^\alpha_{\mu\nu}-g^{\mu\alpha}\delta\Gamma^\nu_{\mu\nu}:=A^\alpha\quad(12.4.815)$$

So that we are left with the following integral expression:

$$\int\nabla_\alpha A^\alpha\sqrt{-g}\mathrm{d}^4x\quad(12.4.816)$$

Using the divergence theorem (see section Vector Calculus page 1882):

$$\int\nabla_\alpha A^\alpha\sqrt{-g}\mathrm{d}\Omega=\int A^\alpha\sqrt{-g}\mathrm{d}\mathcal{S}\quad(12.4.817)$$

As the variational are assumed to vanish on the hypersurface $\mathcal{S}$ of the hypervolume Ω, we have:

$$\int\nabla_\alpha A^\alpha\sqrt{-g}\mathrm{d}\Omega=\int A^\alpha\sqrt{-g}\mathrm{d}\mathcal{S}=0\quad(12.4.818)$$

Therefore our action variational reduces to:

$$\begin{aligned}\delta S&=-\frac{1}{\kappa c}\int\left[\delta g^{ij}R_{ij}\sqrt{-g}-\frac{1}{2}\sqrt{-g}g_{ij}\delta g^{ij}R\right]\mathrm{d}x^4\\&=-\frac{1}{\kappa c}\int\left[R_{ij}-\frac{1}{2}g_{ij}R\right]\delta g^{ij}\sqrt{-g}\mathrm{d}x^4\end{aligned}\quad(12.4.819)$$

For the action to be stationary, the last expression must be equal to zero whatever the variations of the coefficients of the metric δg^{ij}, which imposes that the expression between braces is null:

$$R_{ij}-\frac{1}{2}Rg_{ij}=0\quad(12.4.820)$$

We recognize here the Einstein's field equations without matter! So it seems that our Lagrangian was a good candidate (but it needs more verification, especially, experimental tests!).

12.4.7.1 Einstein-Hilbert action with cosmological constant

Let us try now:

$$S=-\frac{1}{\kappa c}\int(R+\lambda)\sqrt{|g|}\mathrm{d}x^4 \tag{12.4.821}$$

where λ is a constant that we add to the curvature scalar R. The latter relation will obviously be written more explicitly as:

$$S=-\frac{1}{\kappa c}\int(g^{ij}R_{ij}+\lambda)\sqrt{|g|}\mathrm{d}x^4=-\frac{1}{\kappa c}\left[\int g^{ij}R_{ij}\sqrt{|g|}\mathrm{d}x^4+\int\lambda\sqrt{|g|}\mathrm{d}x^4\right] \tag{12.4.822}$$

We already know the result of the first integral as it is simply the previous result we have get. Hence we need to focus only on the second integral!

If we apply as before the variation:

$$\delta S=-\frac{\lambda}{\kappa c}\int\delta(\sqrt{|g|})\mathrm{d}x^4 \tag{12.4.823}$$

and using the fact that we have proved just earlier that:

$$\delta\sqrt{|g|}=\delta\sqrt{-g}=-\frac{1}{2}\sqrt{-g}g_{ij}\delta g^{ij} \tag{12.4.824}$$

We then get:

$$\delta S=-\frac{\lambda}{\kappa c}\int\delta(\sqrt{|g|})\mathrm{d}x^4=-\frac{\lambda}{\kappa c}\int\left(-\frac{1}{2}\sqrt{-g}g_{ij}\delta g^{ij}\right)\mathrm{d}x^4 \tag{12.4.825}$$

Hence the global variation is:

$$\begin{aligned}\delta S&=-\frac{1}{\kappa c}\int\left[\delta g^{ij}R_{ij}\sqrt{-g}-\frac{1}{2}\sqrt{-g}g_{ij}\delta g^{ij}R--\frac{\lambda}{2}\sqrt{-g}g_{ij}\delta g^{ij}\right]\mathrm{d}x^4\\&=-\frac{1}{\kappa c}\int\left[R_{ij}-\frac{1}{2}g_{ij}R-\frac{\lambda}{2}g_{ij}\right]\delta g^{ij}\sqrt{-g}\mathrm{d}x^4\end{aligned} \tag{12.4.826}$$

As before, for the action to be stationary, the last expression must be equal to zero whatever he variations of the coefficients of the metric δg^{ij}, which imposes that the expression between braces is null:

$$R_{ij}-\frac{1}{2}Rg_{ij}-\frac{\lambda}{2}g_{ij}=0 \tag{12.4.827}$$

We recognize here the Einstein's field equations without matter and cosmological constant!

It is because of the shape of that result that the first relation we started with is finally written traditionally (in the purpose to be in agreement with the notation of the General Einstein's field equations):

$$\boxed{S=-\frac{1}{\kappa c}\int(R-2\Lambda)\sqrt{|g|}\mathrm{d}x^4=-\frac{c^3}{8\pi G}\int(R-2\Lambda)\sqrt{|g|}\mathrm{d}x^4} \tag{12.4.828}$$

12.4.7.2 Einstein-Hilbert action with matter

We see that the above result gives use the Einstein's field equations without matter. Ok good but... we want a bit more generalized result. Especially the result we already know:

$$R_{\mu\nu}-\frac{1}{2}Rg_{\mu\nu}=\frac{8\pi G}{c^4}T_{\mu\nu} \quad (12.4.829)$$

So to deduce the corresponding form of the action and corresponding Lagrangian density we will proceed by reverse engineering.

We know that the previous relations will in fact be:

$$R_{\mu\nu}-\frac{1}{2}Rg_{\mu\nu}-\frac{8\pi G}{c^4}T_{\mu\nu}=0 \quad (12.4.830)$$

And if we compare with the previous result:

$$\delta S=-\frac{1}{\kappa c}\int\left[R_{ij}-\frac{1}{2}g_{ij}R\right]\delta g^{ij}\sqrt{-g}\mathrm{d}x^4 \quad (12.4.831)$$

By reverse engineering we will put:

$$\delta S=-\frac{1}{\kappa c}\int\left[R_{\mu\nu}-\frac{1}{2}Rg_{\mu\nu}-\frac{8\pi G}{c^4}T_{\mu\nu}\right]\delta g^{ij}\sqrt{-g}\mathrm{d}x^4 \quad (12.4.832)$$

Ok the variational was very easy to reverse engineer. But for the action and the Lagrangian we are looking for something such that (as we know the origin of the first two terms):

$$\delta(???)=-\frac{8\pi G}{c^4}T_{\mu\nu}\delta g^{ij} \quad (12.4.833)$$

So we will try:

$$\delta\left(\frac{8\pi G}{c^4}T\right)=\delta\left(\frac{8\pi G}{c^4}T_{ij}g^{ij}\right)=\frac{8\pi G}{c^4}\delta\left(T_{ij}g^{ij}\right) \quad (12.4.834)$$

So let see what we get by developing $\delta\left(T_{ij}g^{ij}\right)$. First we must recall that the variational principle request to evaluate the variation of the action in function of the variation of the metric $\delta(g^{ij})$. Therefore:

$$\delta\left(T_{ij}g^{ij}\right)=\underbrace{\delta(T_{ij})g^{ij}}_{=0}+T_{ij}\delta(g^{ij})=T_{ij}\delta(g^{ij}) \quad (12.4.835)$$

And that's it! So the corresponding action is finally:

$$\boxed{S=-\frac{1}{\kappa c}\int\left[R-\frac{8\pi G}{c^4}T\right]\sqrt{-g}\mathrm{d}x^4=-\frac{c^3}{8\pi G}\int\left[R-\frac{8\pi G}{c^4}T\right]\sqrt{-g}\mathrm{d}x^4} \quad (12.4.836)$$

Hence the density Lagrangian:

$$\boxed{\mathcal{L}=\frac{c^4}{8\pi G}R-T=\mathcal{L}_{\text{EH}}+\mathcal{L}_M} \quad (12.4.837)$$

Obviously we can add the cosmological constant to get:

$$\boxed{\mathcal{L}=\frac{c^4}{8\pi G}(R-2\Lambda)-T=\mathcal{L}_{\text{EH},\Lambda}+\mathcal{L}_M} \quad (12.4.838)$$

Remark

There are different ways to derive the above results. Some, as above, use awful and simple reverse engineering reasoning. Others - like the one available on the Wikipedia page of the Einstein-Hilbert action - use circular reasoning about the Stress-Energy tensor and therefore leads to a slightly different expression of the Lagrangian density (implying some constant factor) with the advantage of having a beautiful technical mathematical development (at the opposite of the reverse engineering method...).

If we combine the Lagrangian derived in the section of Electromagnetism, in the section of Special Relativity, in the section of Quantum Theory and the one above of General Relativity, we get so far:

$$\begin{aligned}\mathcal{L}&=\mathcal{L}_{\text{GR}}+\mathcal{L}_{\text{QED}}\\&=\underbrace{\mathcal{L}_{\text{EH},\Lambda}+\mathcal{L}_M}_{\text{General Relativity}}+\underbrace{\mathcal{L}_{\text{DSF}}+\mathcal{L}_{\text{ED}}}_{\text{Quantum Electrodynamics}}\\&=\underbrace{\underbrace{\frac{c^4}{8\pi G}(R-2\Lambda)}_{\text{Einstein-Hilbert}}-\underbrace{T_{\mu\nu}}_{\text{Masse}}}_{\text{General Relativity}}+\underbrace{\underbrace{\bar{\Psi}\left(\mathrm{i}\gamma^\mu\partial_\mu-m_0\right)\Psi}_{\text{Dirac spinor fields}}+\underbrace{-\rho_0c^2\sqrt{1-\frac{v^2}{c^2}}-j^\mu A_\mu+\frac{1}{4}\mu_0F_{\mu\nu}F^{\mu\nu}}_{\text{Electrodynamics}}}_{\text{Quantum Electrodynamics}}\end{aligned}\tag{12.4.839}$$

12.5. Cosmogony

COSMOGONY is concerned with understanding the (hypothetical) birth and evolution of the Universe by the scientific method. It is only through this game between physical theories, models and observations that we will discuss this issue here. We will try to avoid carefully any metaphysical digression. The specific problems of cosmogony fit in its definition: Statistics, that are one of the greatest scientific methods, are apparently poorly efficient for the study of Universe theories as we have only one Universe visible to us at this day. Furthermore, we can only observe the past of our Universe (and furthermore only the observable part...). Can we speak about "predictions" in these conditions? The theories, however, are reliable since they predict behaviours that can be tested by observations.

Cosmogony mainly uses the arsenal of mathematics, theoretical physics, particle physics, nuclear physics, physics of detectors and astrophysics. It is interdisciplinary! Cosmogony deals with scales larger than the size of a galaxy to the scales defined as itself as "Horizon". Even if the limit is deliberately vague, cosmology does not address the internal details of the birth and evolution of astrophysical objects (such as galaxies, globular clusters, and clusters of galaxies) that fall more into the study field of "cosmogony".

quote
12.5:5878.#71

> ❞ *If you can explain a god without a creator, you can explain a Universe without a creator...*

”

By the way... before we start with the maths..., for the answer to the question *Why does the Universe exist?* the reader should know first that the Universe has no obligation to make sense to us! Secondly, the "First Cause Argument" is a human bias! Indeed, through modern science, specifically physics, natural phenomena have been discovered whose causes have not yet been discerned or are non-existent!! The best known example - among many others (!) is radioactive decay! Although decay follows statistical laws and it's possible to predict the amount of a radioactive substance that will decay over a period of time, it is impossible according to our current understanding of physics to predict when a specific atom will disintegrate as we have proved it in the section of Nuclear Physics. The spontaneous disintegration of radioactive nuclei is stochastic and might be uncaused, providing an arguable counterexample to the assumption that everything must have a cause. An objection to this counterexample is that knowledge regarding such phenomena is limited and there my be hidden variables presently unknowns. But this latter objection has been mathematically eliminated (Bell Theorem).

The Universe hasn't inflate obviously for us Homo Sapiens! The fact that we can't survive anywhere else easily outside of the tiny ball of rock and metal - largely inhabitable for us and where most water isn't even pure drinkable water... - we are travelling on without cost-prohibitive and high level technologies just for a one way trip, plus the fact that our little ball of rock and metal has an unstable orbit (perturbed by travelling stars in our Galaxy), is periodically bombarded of extinction level asteroids coming from the Oort cloud or bombarded by gamma rays bursts from potential dying stars, with an unstable long term climate and unstable supervolcano dynamics, and an unstable kernel, and an unstable main star is an obvious evidence! We can also consider as supplementary evidence that all other worlds (planets) we have been able to observed actually that are at a respectable distance for a one-way trip of thousands of years are inhabitable for us... Claiming the opposite is so naive that it is similar as putting a fish in a tiny aquarium in the middle of the desert and listening to the fish claiming the desert was made especially for him...

Also keep in mind that while reading what will follow that the mainstream Big Bang model (cosmic inflation theory) only tell us how matter and energy expanded from an initial dense state to what we observe now. It doesn't state that matter and energy were created during the Big Bang, nor does it tell us where they're coming from (that's more related to the study of quantum cosmology[54]).

Remark

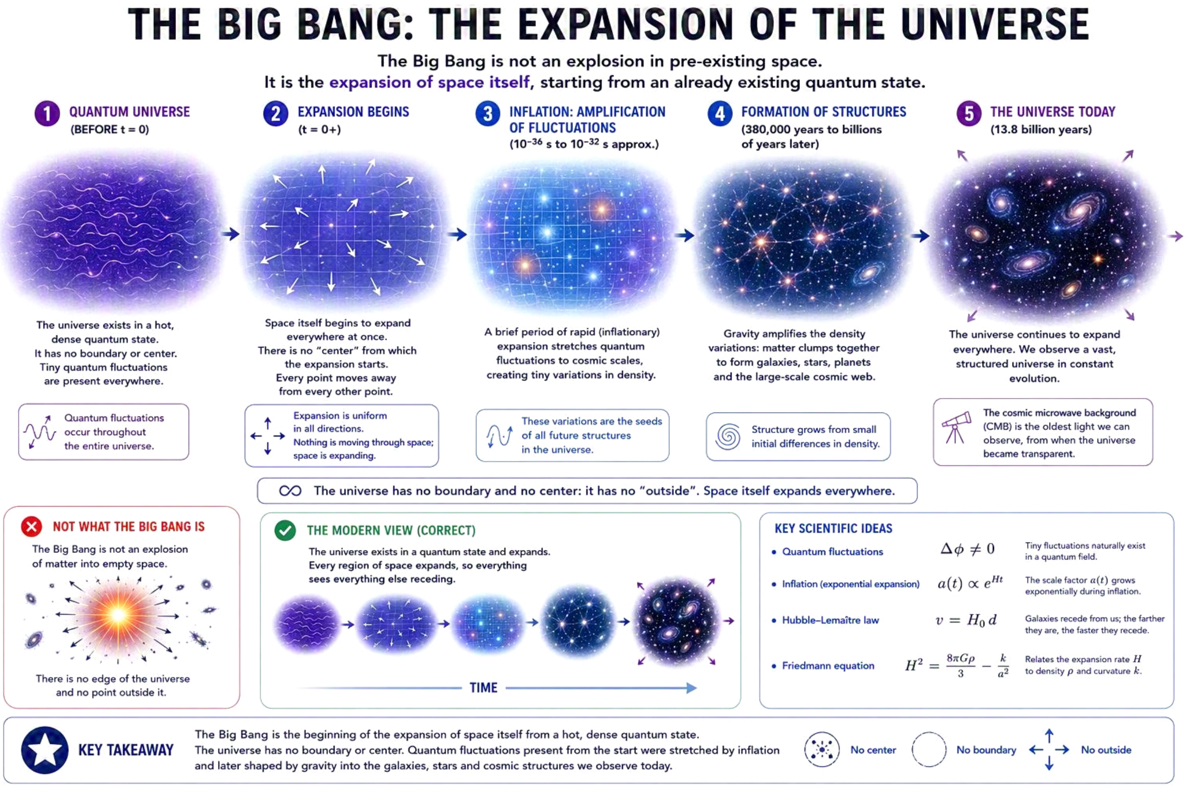
Let us recall the following fact that we have already pointed out in the section of Probabilities: Some scientific illiterate people may argue that Roger Penrose calculated (on the assumption that our Universe is in a Black Hole a with very rough approximations and assumptions...) that for our Universe to be in the low entropy like now is $10^{10^{123}}=10^{123}$ to 1. Hence it is impossible that our Universe is not created by a deity (passing under

---

[54] There are actually (early 121st century according to the holocene calendar) ten theoretical models giving possible answers to what was existing before the Big Bang: Spontaneous Symmetry Break (SSB-Ex nihilo), Quantum tunnelling fluctuation from WdW equation (WdWE), Conformal Cyclic Cosmology (CCC), Steinhardt-Turok Cyclic Cosmology (STCC), Ijjas-Steinhardt Cyclic Cosmology (ISCC), String Gas Cosmology (SGC), Hartle-Hawking no-boundary measure (HHNBM), Loop Quantum Gravity pre-Big-Bang (LQGpBB), Quantum tunnelling fluctuation from Loop Quantum Gravity (QTFLQG), Ekpyrotic Universe...

> silence the question of who created that complex deity...). But it is irrelevant! Even if what he said is 100% accurate or off by a factor of a googol, it's irrelevant!! Indeed, if run a computer program that emulates a coin flipped one billion times and writes the sequence of heads and tails to a file. Great. What we just produced is a sequence more than a trillion trillion trillion times rarer!! In fact, you could run that same computer program until the end of human existence and it would likely never produce that same string of outcomes. And yet it occurred nonetheless...

Definition (#12.5.547): The "Big Bang" (cosmic inflation theory), according to actual cutting edge most promising models, may be either the result of a tunnelling quantum vacuum fluctuation in a true vacuum bubble described by a minisuperspace model in the Wheeler de Witt framework, a symmetry-breaking event in the framework of String Theory or the result of an infinite cyclic conformal universe (in the Penrose framework). It must in no way be considered as a punctual explosion of matter and space-time (that reference was in fact an old joke that most non-specialized scientific medias and religious bigots like to spread even today) nor be considered to be a magical creation by an imaginary friend in the sky. We have anyway no experimental evidence yet in the beginning of the 121st century (holocene calendar) that can confirm beyond reasonable doubt any of the dozens of main different speculative models describing the early and future history of our universe !



THE BIG BANG: THE EXPANSION OF THE UNIVERSE

The Big Bang is not an explosion in pre-existing space.
It is the expansion of space itself, starting from an already existing quantum state.

1 QUANTUM UNIVERSE (BEFORE t = 0)
The universe exists in a hot, dense quantum state. It has no boundary or center. Tiny quantum fluctuations are present everywhere.
Quantum fluctuations occur throughout the entire universe.

2 EXPANSION BEGINS (t = 0+)
Space itself begins to expand everywhere at once. There is no "center" from which the expansion starts. Every point moves away from every other point.
Expansion is uniform in all directions. Nothing is moving through space; space is expanding.

3 INFLATION: AMPLIFICATION OF FLUCTUATIONS (10^{-36} s to 10^{-32} s approx.)
A brief period of rapid (inflationary) expansion stretches quantum fluctuations to cosmic scales, creating tiny variations in density.
These variations are the seeds of all future structures in the universe.

4 FORMATION OF STRUCTURES (380,000 years to billions of years later)
Gravity amplifies the density variations: matter clumps together to form galaxies, stars, planets and the large-scale cosmic web.
Structure grows from small initial differences in density.

5 THE UNIVERSE TODAY (13.8 billion years)
The universe continues to expand everywhere. We observe a vast, structured universe in constant evolution.
The cosmic microwave background (CMB) is the oldest light we can observe, from when the universe became transparent.

The universe has no boundary and no center: it has no "outside". Space itself expands everywhere.

NOT WHAT THE BIG BANG IS
The Big Bang is not an explosion of matter into empty space.
There is no edge of the universe and no point outside it.

THE MODERN VIEW (CORRECT)
The universe exists in a quantum state and expands. Every region of space expands, so everything sees everything else receding.

KEY SCIENTIFIC IDEAS

Quantum fluctuations	$\Delta\phi \neq 0$	Tiny fluctuations naturally exist in a quantum field.
Inflation (exponential expansion)	$a(t) \propto e^{Ht}$	The scale factor $a(t)$ grows exponentially during inflation.
Hubble–Lemaître law	$v = H_0 d$	Galaxies recede from us; the farther they are, the faster they recede.
Friedmann equation	$H^2 = \frac{8\pi G\rho}{3} - \frac{k}{a^2}$	Relates the expansion rate H to density ρ and curvature k.

KEY TAKEAWAY
The Big Bang is the beginning of the expansion of space itself from a hot, dense quantum state. The universe has no boundary or center. Quantum fluctuations present from the start were stretched by inflation and later shaped by gravity into the galaxies, stars and cosmic structures we observe today.

In a survey made on 80 professional physicists (see [96]) in 12024 (holocene calendar) we get the following result for the fate of the matter that falls into a Black Hole:

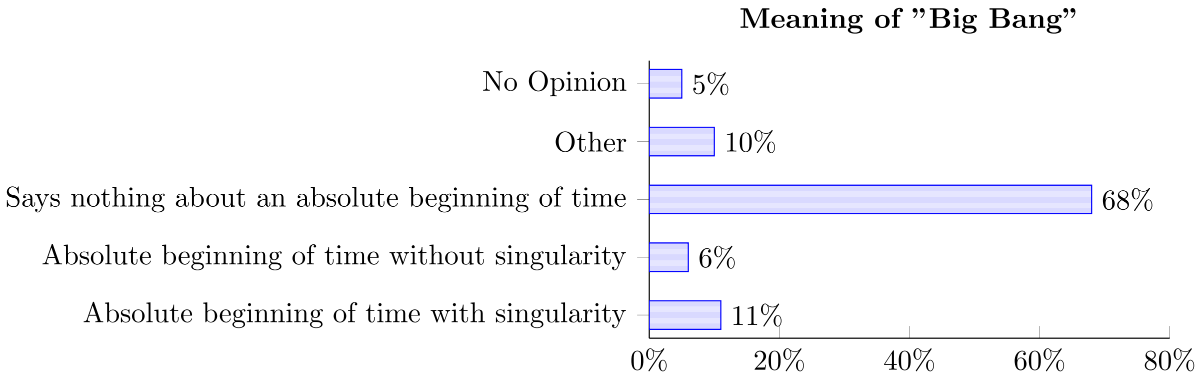


Figure 12.250: **Copenhagen survey on how the "Big Bang" should be understood**

12.5.1 Newtonian (i.e. non-relativistic) Cosmological Models

A cosmological model is a mathematical representation of the Universe that seeks to explain the reasons for its present appearance, and describe its evolution over time (named "cosmological time") but not its creation!

The Newtonian model (also named "non-relativistic cosmology") applies under the assumptions of Newtonian mechanics (instantaneous action for example). The results we are going to study here were discovered before the development of General Relativity but published after! But this Newtonian model has the advantage, even if sometimes the mathematical assumptions and manipulations are very quite wrong, of simplicity while being able to identify and discuss the dynamics of the Universe and to prepare for the study of the Universe models making use of the results of General Relativity afterwards. Its disadvantage, besides the fact that it doesn't quite fit the experimental results, it is to be no longer valid under extreme conditions and therefore cannot be extrapolated to the instant of the Big Bang.

Before we begin, we must define the "cosmological principle" consisting of the following two assumptions (basically, it ensures that we are not privileged observers, and that what we are seeing is a representative of the whole of the Universe):

H1. The space (the Universe) is homogeneous, that is to say, it has the same properties in all its regions. This must be at a very large scale, beyond the thousand Mpc (megaparsecs). It is clear that small-scale inhomogeneities exist... we for example... ☺

H2. The space (Universe) is isotropic[55] at large scales, that is to say, there is no specific direction in space, such as flattening a direction or an overall movement on a Universal scale for example and all its physical properties are almost identical in any point.

For an in-deep discussion and criticism of the subject based on the earliest experimental data (of this early 121st century according to holocene calendar), the reader can refer to the excellent

---

[55] There is a disagreement in the beginning of the 121st century (holocene calendar) about this assumption that need more precise studies. Some physicists have a statistical evidence of a "dark flow" in the CMB - providing at the same time a possible argument for Multiverse model - some say it is only a noise. To follow...

100 pages paper *Is the observable Universe consistent with the cosmological principle?* (see [15]).

Remark

This hypothesis of the isotropy of the Universe and that works relatively well in theoretical models (see below) requires an interesting fact if we admit a beginning to the Universe. This fact implies that the Universe had a phase in its history where it did not leave the time to the matter to clump together to form from its beginnings inhomogeneous and anisotropic material groups that are visible today in our telescopes. Therefore it follows that at a moment of its history, the Universe had a non-quasistatic expansion rate that we could make match with the speed of light (this is badly formulated but I hope it is still acceptable in the idea).

The figure below shows the Automated Plate Measurement (APM) Galaxy Survey. Over 2 million galaxies are depicted in a region of 100 degrees across centered toward the Milky Way's south pole:

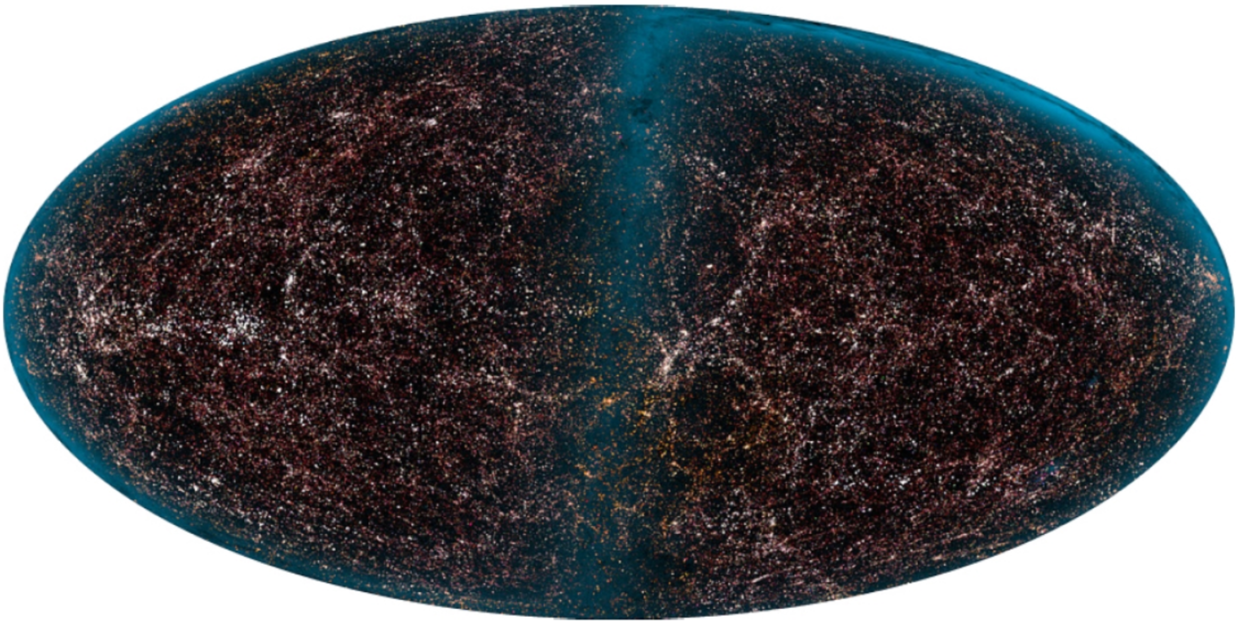

Figure 12.251: **Automated Plate Measurement (APM) Galaxy Survey**

We will also request other working assumptions/hypothesis:

H1. The Universe is a non viscous gaseous fluid whose particles are galaxies. Assuming the cosmological principle, the movement of galaxies, constituents in-fine of this "fluid" by construction, are statistically at rest.

H2. The Universe is a thermodynamically closed system, without work and adiabatic (no heat exchange with the outside).

H3. The Universe in a homothetic expansion (in uniform expansion in all its dimensions) is taken as having a spherical shape with a center (at least in the Newtonian model...).

H4. Its density is only a function of time and there is mass conservation (and therefore energy). Therefore the amount of material is constant (yes this is always the Newtonian model...)!

H5. We accept the Newtonian dynamics (approximation of General Relativity) to build the Newtonian models that will follow.

H6. The origin of time is treated as the origin of creation (horizon) of the Universe and repository of study is comoving with the particles (and therefore moves with the galaxies placed on the space-time pattern) and named "reference material" (galaxies are stationary in this repository!).

12.5.1.1 Hubble's Law

Assuming the cosmological principle and the above assumptions, the distance from an origin point O to any point M of the universe can vary in function of time (in a undetectable way to the human scale) in the form:

$$\overrightarrow{\mathrm{O}M}(t)=\overrightarrow{\mathrm{O}M}(t_0)F(t) \quad (12.5.1)$$

where $F(t)$ is the "scaling factor" (denoted by $R(t)$ or even $a(t)$ depending on the context...).

Notice that we can't have $\overrightarrow{\mathrm{O}M}(t_0)=0$ otherwise, whatever the value of $F(t)$, $\overrightarrow{\mathrm{O}M}(t)$ would always be equal zero... (this eliminate the theoretical possibility that the Universe may have had one day no size!). Also notice that $F(t)\in\mathbb{R}^+\backslash\{0\}$, i.e. that means that the size of the Universe may decrease or increase in size but never come to a size equal to zero!

Caution! There is a theorem (see [64]), in the framework of General Relativity, famous among cosmologists, showing that an inflationary universe is past-timelike-incomplete (we will provide the proof of that theorem in the future). What this means, explicitly, is that if you have any particles that exist in an inflating Universe, they will eventually meet if you extrapolate back in time. This doesn't, however, mean that there must have been a singularity, but rather that inflation doesn't describe everything that occurred in the history of the Universe, like its beginning. We also know, for example, that inflation cannot arise from singular state, because an inflating region must always begin from a finite size.

In writing this relation, we consider that the points O and M are on a plane of zero curvature. Indeed, if we imagine two points on a circular curved surface (e.g. the surface of a sphere) let us see what happens:

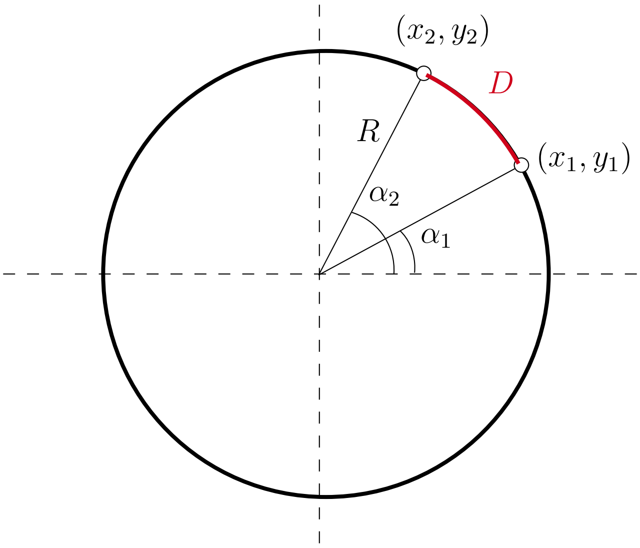

Figure 12.252: **Illustration of the validity limit of the model**

The distance between two points on the circle (i.e. spherical space) is given by (see section

Trigonometry page 2542):

$$D=R\Delta\alpha=R(\alpha_2-\alpha_1)=R\left(\arcsin\left(\frac{y_2}{R}\right)-\arcsin\left(\frac{y_1}{R}\right)\right)=R\left(\arccos\left(\frac{x_2}{R}\right)-\arccos\left(\frac{x_1}{R}\right)\right) \tag{12.5.2}$$

We see very well in this relation that if the radius (of the spherical Universe) changes by a factor F, then the change in the distance between the two points is not linearly proportional to this factor!! Which is not the case in a zero curvature plane!

Consequence: Our Newtonian model is valid only in a flat universe where General Relativity or purely classical energy approach (see further below) can take into account different types of curvature!

We see immediately that the relation:

$$\boxed{\overrightarrow{\mathrm{O}M}(t)=\overrightarrow{\mathrm{O}M}(t_0)F(t)} \tag{12.5.3}$$

is independent of the chosen origin, in fact, if we apply it on any two points A, B we have:

$$\overrightarrow{\mathrm{O}A}(t)=\overrightarrow{\mathrm{O}A}(t_0)F(t) \qquad \overrightarrow{\mathrm{O}B}(t)=\overrightarrow{\mathrm{O}B}(t_0)F(t) \tag{12.5.4}$$

Then by difference:

$$\overrightarrow{AB}(t)=\overrightarrow{AB}(t_0)F(t) \tag{12.5.5}$$

Remark

At the time t_0 it is obvious that the above equation is:

$$\overrightarrow{AB}(t_0)=\overrightarrow{AB}(t_0)F(t_0) \tag{12.5.6}$$

and imposes $F(t_0)=F(0)=1$. This is important and we will come back on it many times during the developments that will follow.

The law above therefore applies to any segment $\overline{AB}$ in the Universe. This is why the Universe has no geometrical center (at least as far as we know) and that we can represent ourselves the expansion of the frame of the Universe: consider a half-inflated balloon on whose surface we draw two marks (eg: two crosses drawn with ink). Inflating the balloon more we find that these two cross diverge from each other and therefore the distance between them will increase. This is what we are seeing with the galaxies:

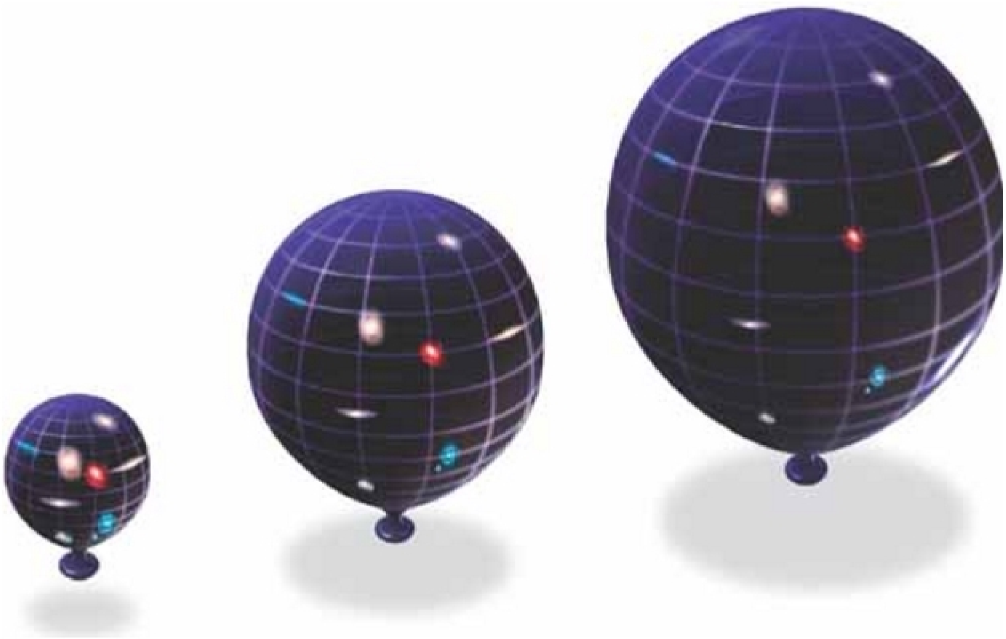

Figure 12.253: **Illustration of the inflated balloon Universe model**

Remarks

R1. If the Universe is expanding, why aren't we? The reason for this is that there are other physical phenomena at play besides the Universe's expansion. On small scales, like animal-sized and below, electromagnetism and nuclear forces dominate. On larger scales, like that of planets, Solar Systems and galaxies, gravitational forces dominate. On the largest scales of all, the expansion wins. But there are also smaller scales, where the expansion has been overcome, at least locally. The Virgo cluster itself will remain gravitationally bound. The Milky Way and all the local group galaxies will stay bound together, and eventually merge under their own gravity. It's only on the largest scales of all, where all the binding forces between objects are too weak to defeat the speedy Hubble rate, that expansion occurs at all.

R2. If the Universe expands, then where it expands to? The Universe isn't expanding into anything. If there is something "beyond" the Universe, that would, by construction, also be part of the Universe. Our limited human intuition usually fails us on this concept because we think of the Big Bang as an explosion and explosions expand into their surrounding space. The Universe, however, is not surrounded by more space. The analogy with the inflating balloon in the figure above helps to grasp the concept (even if as always, this analogy is also a false equivalence!). Not the 3D volume of the balloon, but the 2D surface of the balloon is our Universe. And as the reader can see, it's expanding itself and does not have any border!

Deriving with respect to time the relation:

$$\overrightarrow{\mathrm{O}M}(t)=\overrightarrow{\mathrm{O}M}(t_0)F(t) \tag{12.5.7}$$

The first member then gives the particle velocity (or other any object) to the point $\vec{r}(t)=\overrightarrow{\mathrm{O}M}(t)$:

$$\vec{v}(\vec{r},t)=\overrightarrow{\mathrm{O}M}(t_0)\mathrm{d}_tF(t)=\vec{r}(t_0)\mathrm{d}_tF(t) \tag{12.5.8}$$

Therefore eliminating $\overrightarrow{\mathrm{O}M}(t_0)$ (we see that if we have $F(t)=0$ we have indeed an issue or a... "singularity"...) we get:

$$\vec{v}(\vec{r},t)=\frac{\overrightarrow{\mathrm{O}M}(t)}{F(t)}\mathrm{d}_tF(t)=\frac{\vec{r}(t)}{F(t)}\mathrm{d}_tF(t)=\frac{1}{F(t)}\mathrm{d}_tF(t)\vec{r}(t) \tag{12.5.9}$$

We put to simplify the notations:

$$H(t)=\frac{1}{F(t)}\mathrm{d}_tF(t) \tag{12.5.10}$$

Therefore we have:

$$\boxed{\vec{v}(\vec{r},t)=H(t)\vec{r}(t)} \tag{12.5.11}$$

This relation is known as the "Hubble law" or "velocity-distance relation" and which, according to historical research should have for paternity rather Georges Lemaître... That's why it is sometimes named the "Hubble-Lemaître law". However... (!) although widely attributed to Edwin Hubble or Georges Lemaître, the notion of the universe expanding at a calculable rate was first derived from General Relativity equations in 11922 (holocene calendar) by Alexander Friedmann and five year afters in a very different shape ($\mathrm{d}\lambda/\lambda=r/R_0\sqrt{3}$) by Lemaître. But that effect was already known experimentally and modelized in 11914 (holocene calendar) by Vesto Slipher and written for the first time in it's modern shape in 11928 (holocene calendar) by Howard P. Robertson (see [501] for all the details).

Before going further, it is necessary to pause on this equation for the present moment:

$$\vec{v}(\vec{r},t_0)=H(t_0)\vec{r}(t_0)=H_0\vec{r}_0 \tag{12.5.12}$$

This equation says that the object of the Universe recede with a speed proportional to their distance in all points of the Universe without special repository (no galaxy seems to be fixed while they are in the material repository!).

Remark

This relation allows for speeds higher than those of light... But this is not a violation of Special Relativity regarding the constancy of the speed of light! Indeed, we must not forget that the Hubble law takes into account the expansion of the "frame" of space-time on which light moves. Also Special Relativity deal with speed of light and not with speed of space itself. Keep in mind that the expansion of the Universe doesn't have a "speed" (typical error of amateur scientists!). Therefore if the frame extends along an expansion factor F greater than one, it gives the impression that light travels faster than c, and this is what gives sometimes a redshift value of 4 or 5 or even 11.09 (the actual record)!

The idea of even talking about "the expansion velocity of the universe" is bizarre and never should have been entertained in the first place in massmedia and especially because there is no well-defined notion of "the velocity of distant objects" in General Relativity (there is simply no such thing as the "velocity" between two objects that aren't in a first approximation located in the same place!). So the fact that some people think that what's special about the so named "inflation" is that the Universe was expanding faster than light is a crime against comprehension and good taste (what's special about inflation is only that the universe is accelerating!).

The constant $H(t_0)=H_0$ being of course being identifiable to the "Hubble constant[56]" (but that is not a constant...) and currently measured in this early 12000s (holocene calendar) as being approximately equal[57] $\sim 67.66\,[\text{km}\cdot\text{s}^{-1}\cdot\text{Mpc}^{-1}]$. That means that for every million parsecs of distance from an observer, the rate of expansion increases by about 67.66 kilometres par second! In SI Units that's equal to approximately $2.4\cdot 10^{-18}\,[\text{s}^{-1}]$ (the reader should always refer to the most recent published scientific papers to get the actual value!).

We can actually calculate an estimate for the age of he Universe from Hubble's Law. Let us consider that the actual distance between two galaxies is D. The apparent velocity with which they are separating from each other is v. At some point, the galaxies were touching, and we can consider that time the moment of the Big Bang. If we take the separation between the two galaxies (D) and divide that by the apparent velocity (v), that will leave us with how long it took for the galaxies to reach heir current separation.

So, the time it has taken for the galaxies to reach their current separations is $t=D/v$. But, from Hubble's Law, we know that $v=H_0D$. Therefore:

$$t=\frac{D}{v}=\frac{D}{H_0\cdot D}=\frac{1}{H_0} \qquad (12.5.13)$$

So, we can take $1/H_0$ as an estimate for the age of the Universe (as we know that very likely H_0 isn't a constant).

The best estimate at the day we write these line being $H_0\cong 67.66\,[\text{km}\cdot\text{s}^{-1}\cdot\text{Mpc}^{-1}]$. To turn this into an age, we'll have to do a unit conversion obviously!

Since $1\,[\text{Mpc}]=3.085\cdot 10^{19}\,[\text{km}]$, therefore:

$$H_0\cong\frac{67.66\,[\text{km}\cdot\text{s}^{-1}\cdot\text{Mpc}^{-1}]}{3.085\cdot 10^{19}\,[\text{km}\cdot\text{Mpc}^{-1}]}\cong 2.193\cdot 10^{-18}\,[\text{s}^{-1}] \qquad (12.5.14)$$

So, the age of the Universe based on this approximately equal to the "Hubble time":

$$\boxed{t_H=\frac{1}{H_0}\cong 4.5596\cdot 10^{10}\,[\text{s}]\cong 14.48\cdot 10^{9}\,[\text{years}]} \qquad (12.5.15)$$

that is to say about 14.5 billion years ago (we will see further below a better approach to calculate the age of our Universe). Taking into account margin of error of early 121st century measurements (holocene calendar), the upper bound age is 14.5 billions years and lower bound is 13.2 billion years.

---

[56] We should rather speak of "Hubble parameter" as it is not constant through time (since there are dynamical forces acting on the particles in the Universe which affect the expansion rate).

[57] The last value (12018-07-18) to $67.66\pm 0.42\,[\text{km}\cdot\text{s}^{-1}\cdot\text{Mpc}^{-1}]$. But there is still in year 12021 (holocene calendar) a 5σ tension in the estimation of H_0 between the direct measurement method and the indirect measurement method as beautifully summarised in the paper [144] at page 10 (paper that also summarizes the few hundred of theoretical alternatives and improved versions of the ΛCDM model).

Caution! As we will prove it further below (see page 5916), the Hubble time is strictly speaking not the age of our universe. The fact that the Hubble time is approxomitely equal to the age of our Universe is a reflection that the rate of expansion has been nearly constant for a long time. In reality, the best cosmological theories suggest that the universe has not been expanding linearly since the beginning. So we would expect that the age of the universe is not exactly equal to the Hubble time. But hopefully it makes sense that if any non-linear expansion lasted for only a short period, then the Hubble time should still be close to the age of the universe. That is the situation we see today. And the reader must not forget that the Hubble constant is not a constant (!!!) hence the Hubble time isn't also a constant. For example 6 billion years ago, when the universe was 7.5 billion years old, the Hubble constant was about $100\,[\text{km}\cdot\text{s}^{-1}\cdot\text{Mpc}^{-1}]$, what means the Hubble time was 9.78 billion years. When the universe will be 24 billion years of age, H will be $60\,[\text{km}\cdot\text{s}^{-1}\cdot\text{Mpc}^{-1}]$, and the Hubble time will be 16.3 billion years. Not even close to the age of the universe!

Here is the evolution of the precision of measurement of the Hubble constant:

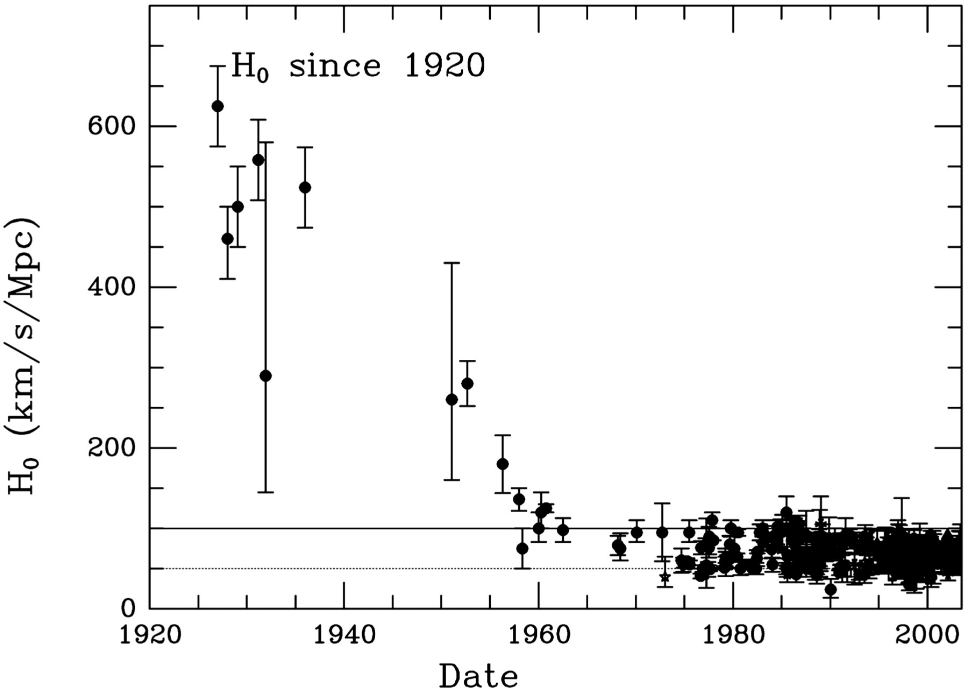

Figure 12.254: **Evolution of Hubble parameter estimations (source: Robert P. Kirshner)**

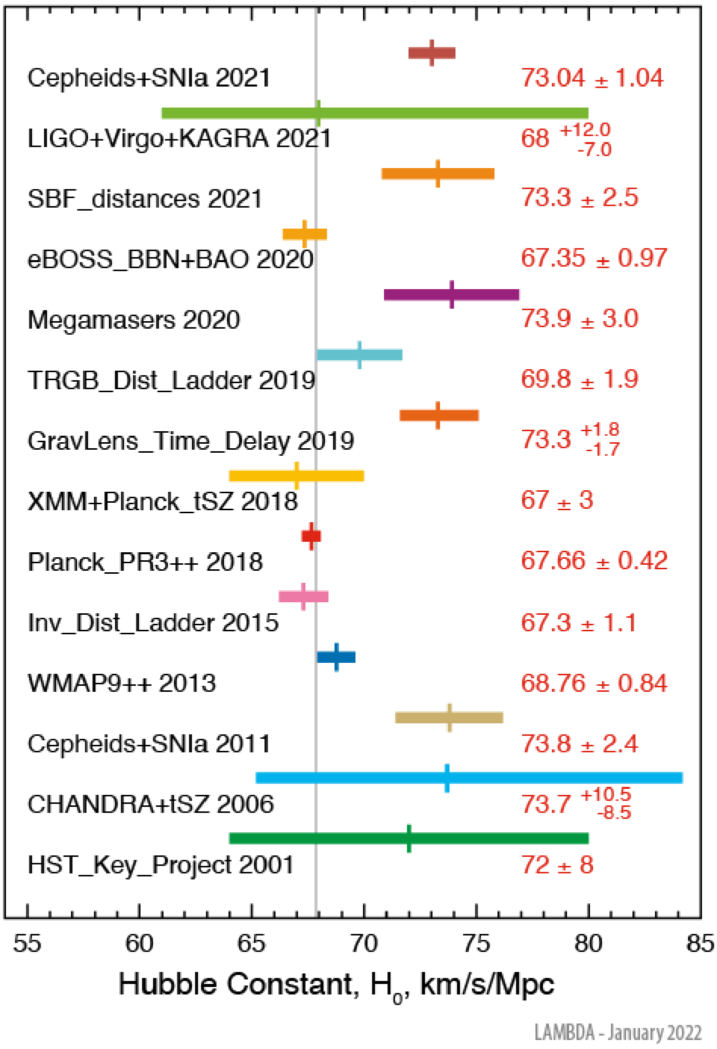
And some recent measurement at the days we write these lines:



Conversely, we can have fun to calculate the distance from which we (i.e. the observed galaxies) can reach the speed thanks to the equation:

$$\vec{v}(\vec{r},t_0)=H(t_0)\vec{r}(t_0)=H_0\vec{r}_0 \tag{12.5.16}$$

and a numerical application gives roughly 13 billion light years. This is the distance of the "cosmological horizon".

In cosmology, a "Hubble volume, or "Hubble sphere", is a spherical region of the Universe surrounding an observer beyond which objects recede from that observer at a rate greater than the speed of light due to the expansion of the Universe. Regarding the relation we get above, the corresponding radius today is given by (assuming that the Hubble parameter has always been constant):

$$r_{\text{HS}}(t_0)=\frac{c}{H_0}=\frac{299,792.458}{67.66}\cong 4430.86\,[\text{Mpc}]\cong 14.4\cdot 10^9\,[\text{light-years}] \tag{12.5.17}$$

hence almost equal to 14 billion light-years. As observations seem to indicate that our Universe is accelerating, some objects that we can currently exchange signals with, will one day cross our Hubble limit!

But... it takes almost 14.4 billion light-years under these assumptions to reach us so it could have moved another 14.4 billion light years away from us during that time... (still under the same assumptions!). So the "complete radius" would be 28 billion light years away! Then what we will name in the books the "Newtonian radius" of our Universe - not to be confused with the entire Universe - under these assumptions is:

$$r_{\text{Newt. Universe}}(t_0) = r_{\text{HS}} \cong 28.8 \cdot 10^9 \text{ [light-years]} \qquad (12.5.18)$$

Caution! We name this radius of our Universe in this textbook "Newtonian radius" because it's obviously wrong in the framework of General Relativity as we will prove it much further below (see page 6048)! The calculations involving General Relativity and the Friedmann-Lemaître-Robertson-Walker metric give for our observable Universe + our unobservable Universe a radius actually a little bit greater than 40 billion light years (with a margin of error of a few hundred of million of years).

In other words, knowing that the huge majority of galaxies are escaping from our Milky Way, this result has a quite important conclusion: in a far future, the sky as seen from our Galaxy (or what will remain of it...), will be completely dark as (almost) everything will be moving away at a speed greater than that of light! So we are "lucky" to observe the Universe at it is today as otherwise the cosmological model would have been much more harder to establish without the observation of other galaxies... (and keep in mind that this is an effect strictly relative to the observer!).

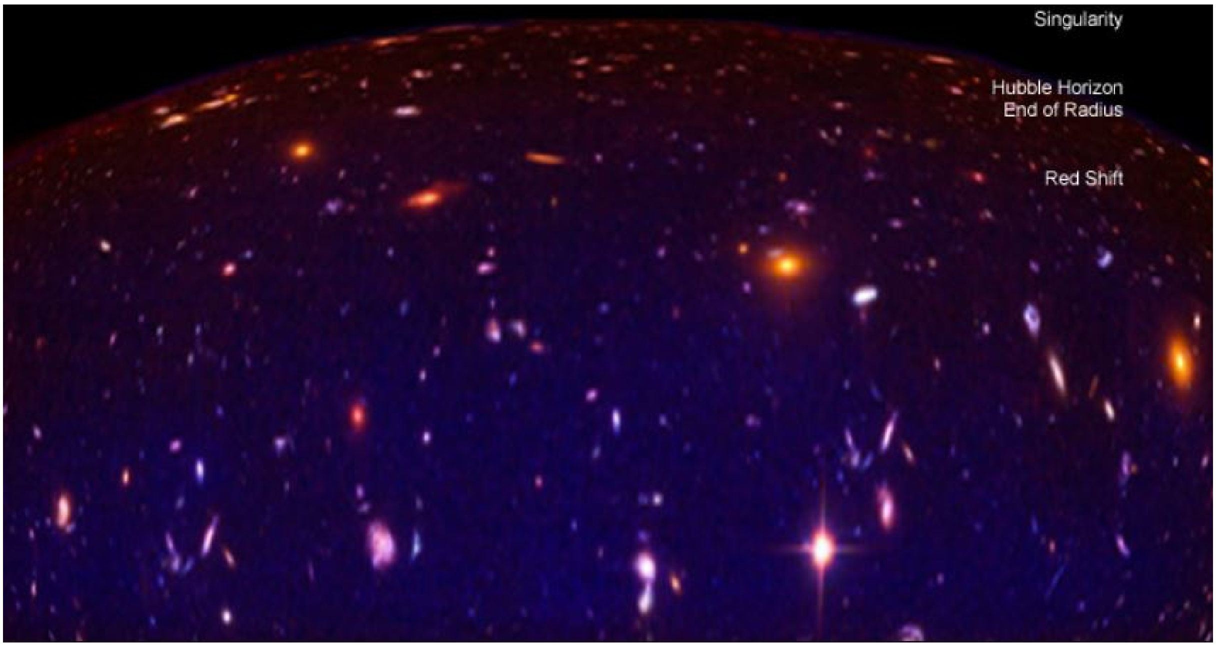


Figure 12.255: An artistic concept of the Hubble Horizon (source: ?)

12.5.2 Friedmann Equations (Newtonian derivation)

Consider now a spherical ring of material of radius r and of constant mass m expanding at velocity v, and containing a ball of material of mass M (also in expansion at speed v).

$$\frac{1}{2}mv^2-\frac{GMm}{r}=k_1 \tag{12.5.19}$$

where k_1 is a constant. By dividing by m and replacing each member M by its expression as a function of the density, we get:

$$\frac{1}{2}v^2-\frac{4\pi}{3}\frac{G\rho r^3}{r}=\frac{k_1}{m} \tag{12.5.20}$$

Remark

If it can help the reader to understand what we did with the term of the potential energy, he can refer to section Classical Mechanics when we developed the calculations of the potential energy of a material sphere (see page 3356).

But Hubble's law gives us according to what we saw just earlier above:

$$v=Hr \tag{12.5.21}$$

and:

$$r=r_0F \tag{12.5.22}$$

We get:

$$\frac{1}{2}H^2r_0^2F^2-\frac{4\pi}{3}G\rho r_0^2F^2=\frac{k_1}{m} \tag{12.5.23}$$

That we simplify in:

$$H^2=\frac{8\pi}{3}G\rho+\frac{2k_1}{mr_0^2}F^{-2} \tag{12.5.24}$$

However, k_1,m,r_0 are constants. We introduce a new constant k defined by (to simplify the notations):

$$k=-\frac{2k_1}{mr_0^2} \tag{12.5.25}$$

So we get the equation:

$$\boxed{H^2=\frac{8\pi G}{3}\rho-kF^{-2}} \tag{12.5.26}$$

which is none other than the "Friedmann's first equation" that we frequently find in the literature as follows (among others notations...):

$$H^2=\left(\frac{R'}{R}\right)^2=\frac{8\pi G\rho}{3}-\frac{k}{R^2} \tag{12.5.27}$$

It is possible to obtain the same equation, but in a much more general and rigorous way, from Einstein's field equations (see section General Relativity page 5766) and the metric of Friedmann-Lemaître-Robertson-Walker (see further below page 5987).

Let us still notice a very common form of that relation. When using Einstein's mass and energy equivalence ($E = mc^2$) the above density ρ is no longer a mass density but an energy density, we will have to divide it again by the squared speed of light to have a mass density again. It is the same if at the denominator of the constant k, the mass m is replaced by energy, then we will have to multiply k by the squared speed of light to fall back on a mass. We then have, denoting now the scale factor by a (as it is often customary in the literature) and redistributing the terms, the following form of the first Friedmann equation:

$$H^2 = \left(\frac{a'}{a}\right)^2 + \frac{kc^2}{a^2} = \frac{8\pi G\rho}{3c^2} \tag{12.5.28}$$

where a is also known as the "cosmic scale factor" or sometimes the "Robertson-Walker scale factor" or "Robertson-Walker radius".

The latter relation is also commonly written:

$$\boxed{\left(\frac{\dot{a}}{a}\right)^2 = \frac{8\pi G\rho}{3c^2} - \frac{k}{a^2}} \tag{12.5.29}$$

or:

$$\frac{\dot{a}^2 + k}{a^2} = \frac{8\pi G\rho}{3c^2} \tag{12.5.30}$$

These equations were derived in 11922 (holocene calendar) by Friedmann, seven years before Hubble's discovery, when Albert Einstein did not trust his own equations because they did not allow the universe to be static. Also Friedmann's equation did not gain recognition until after his death, when they were confirmed by an independent derivation by Georges Lemaître in 11927 (holocene calendar).

Remark

Albert Einstein added to this equation for personal and quasi-religious beliefs a cosmological constant that allowed him to make static the scale factor of the Universe. I (as the main redactor of the book) reject this arbitrary constant (at least until this date), even if in the contemporary physics, it has become a trendy constant (its value was defined more mathematically rather than religiously) because it would explain the origin of a supposed "dark energy" that seems to accelerate the expansion of our Universe (this acceleration could also be a "local" departure of the Hubble parameter from its globally averaged value perhaps caused by a local void in the mass density of our space neighbourhood named a "Hubble bubble"), the current laws of our Universe, the inflationary period of our universe and its geometry. Thus, the first Friedmann equation with the cosmological constant, which is a total artifice of work, is then:

$$H^2 = \frac{8\pi G}{3}\rho - kF^{-2} + \frac{\Lambda}{3} \tag{12.5.31}$$

with:

$$\Lambda=\frac{8\pi G}{c^4}F \tag{12.5.32}$$

This is Andrei Sakharov who defined the value of the above cosmological constant, which supposedly corresponds to the quantum energy of vacuum (depending on the Higgs fields).

In quantum physics the equations of the field associated with elementary particles that are used to define the Big Bang theory (cosmic inflation theory) are one of the main flow of the beginning of this 121st century (holocene calendar). The famous Einstein's field equations tells us that energy is associated with a gravitational field like the electron in motion is associated with an electromagnetic field. It follows from these two observations that by measuring the gravitational field we have a way to determine the energy of vacuum. The gravitational field is no longer about the matter but about the energy density of vacuum. But the cosmological constant is directly proportional to the constant of gravity G. Its measurement is a quite very dangerous game because its value depends on several fundamental laws of physics and of significant properties on the dynamics of our Universe. The debate remains completely open and if I (the main redactor of this textbook) find a valid and rigorous proof of this constant, we will provide to the reader the consequences of this constant on the models that we will see below.

Let us now use the first law of thermodynamics (see section Thermodynamics page 3618) for a system by definition that will be closed and isolated, which the sum of kinetic and potential energy is constant (and therefore the amount of total energy variation is zero for these two energies). We then have that the change in total energy is only given by the variation of internal energy (the most common case in thermodynamics for macroscopic objects):

$$\mathrm{d}E_{\text{tot}}=\mathrm{d}U \tag{12.5.33}$$

and we have also proven in the section of Thermodynamics the characteristic equation of a fluid in equilibrium (see page 3658):

$$\mathrm{d}U=T\mathrm{d}S-P\mathrm{d}V \tag{12.5.34}$$

If the system is adiabatic (no heat transfer between the system and outside), then we have also proven in the section of Thermodynamics that the variation of entropy was (see page 3660 3660):

$$\mathrm{d}S=\frac{\delta Q}{T}=\frac{0}{T}=0\Leftrightarrow\frac{\mathrm{d}S}{\mathrm{d}t}=0 \tag{12.5.35}$$

Then:

$$\mathrm{d}U+P\mathrm{d}V=0 \tag{12.5.36}$$

Assuming the universe being spherical (...), we have:

$$V=\frac{4}{3}\pi R^3 \tag{12.5.37}$$

and in the material repository where galaxies (cosmic fluid particles) are immobile:

$$U=E_{\text{tot}}=mc^2=\rho Vc^2 \tag{12.5.38}$$

Therefore:

$$\mathrm{d}(\rho Vc^2)+P\mathrm{d}\left(\frac{4}{3}\pi R^3\right)=\mathrm{d}\left(\rho\frac{4}{3}\pi R^3c^2\right)+P\mathrm{d}\left(\frac{4}{3}\pi R^3\right)=0 \tag{12.5.39}$$

which simplifies in:

$$\mathrm{d}(\rho R^3c^2)+P\mathrm{d}(R^3)=0 \tag{12.5.40}$$

taking the derivative with respect to the cosmic time t:

$$\begin{aligned}c^2\frac{\mathrm{d}(\rho r^3)}{\mathrm{d}t}+P\frac{\mathrm{d}(R^3)}{\mathrm{d}t}&=c^2\dot{\rho}R^3+c^2\rho 3R^2\dot{R}+3PR^2\dot{R}\\&=c^2\dot{\rho}R^3+3R^2(c^2\rho+P)\dot{R}=0\end{aligned} \tag{12.5.41}$$

therefore we get the "Universe fluid equation" or Universe continuity equation" (for a spherical universe!):

$$\dot{\rho}=-3\left(\rho+\frac{P}{c^2}\right)\frac{\dot{R}}{R} \tag{12.5.42}$$

of denoted in textbooks:

$$\boxed{\dot{\rho}+3\frac{\dot{a}}{a}\left(\rho+\frac{P}{c^2}\right)=0} \tag{12.5.43}$$

There is another way (more beautiful but much more technical) to derive the above equality. Indeed, we will prove much later that (see page 6004):

$$\Gamma^{r'}_{0r'}=\Gamma^{r'}_{r'0}=\frac{\dot{a}}{ca}\qquad\Gamma^{\theta}_{0\theta}=\Gamma^{\theta}_{\theta 0}=\frac{\dot{a}}{ca}\qquad\Gamma^{\phi}_{0\phi}=\Gamma^{\phi}_{\phi 0}=\frac{\dot{a}}{ca} \tag{12.5.44}$$

Therefore:

$$\Gamma^{r'}_{r'0}+\Gamma^{\theta}_{\theta 0}+\Gamma^{\phi}_{\phi 0}=3\frac{\dot{a}}{ca} \tag{12.5.45}$$

Before plugging in to Einstein's equations, it is educational to consider the zero component of the conservation of energy equation:

$$\nabla_\mu T^\mu_0=0 \tag{12.5.46}$$

As we have seen in the section of Tensor Calculus during our study of the covariant derivative (see page 2113) that:

$$\nabla_\mu T^\mu{}_\nu=\partial_\mu T^\mu{}_\nu+\Gamma^\mu_{\mu\lambda}T^\lambda{}_\nu-\Gamma^\lambda_{\mu\nu}T^\mu{}_\lambda=0 \tag{12.5.47}$$

and also remember that[58]:

$$T^\mu{}_\nu=g^{\mu\lambda}T_{\lambda\nu}=\mathrm{diag}(\rho c^2,-P,-P,-P) \tag{12.5.48}$$

---

[58] The reader must notice here that we take the special case of a flat Minkowski metric because otherwise we have no conservation of energy! That's why physically in General Relativity, asymptotically flat space-times represent isolated systems

we have then (keep in mind that one of the stress-energy tensor index is lowered thanks to the metric hence the change of signs below after the second equality):

$$\begin{aligned}\nabla_\mu T^\mu{}_0 &= \partial_\mu T^\mu{}_0 + \Gamma^\mu_{\mu 0} T^0{}_0 - \Gamma^\lambda_{\mu 0} T^\mu{}_\lambda = \partial_t(\rho c^2) + 3\frac{\dot a}{ca}\rho c^2 - \left(-3\frac{\dot a}{ca}\right) P \\ &= \frac{\partial \rho c^2}{\partial(ct)} + 3\frac{\dot a}{ca}\left(\rho c^2 + P\right) = \dot\rho c + 3\frac{\dot a}{a} c\left(\rho+\frac{P}{c^2}\right) = 0\end{aligned} \qquad (12.5.49)$$

Let's finally simplify the last equality by dividing both sides by c to fall back on:

$$\dot\rho + 3\frac{\dot a}{a}\left(\rho+\frac{P}{c^2}\right) = 0 \qquad (12.5.50)$$

Now let us take again the first Friedmann equation, obtained earlier above, in the form:

$$\left(\frac{\dot R}{R}\right)^2 = \frac{8\pi G\rho}{3} - \frac{k}{R^2} \qquad (12.5.51)$$

and let us write it as follows:

$$\dot R^2 = \frac{8\pi G\rho r^2}{3} - k \qquad (12.5.52)$$

If we differentiate:

$$\frac{\mathrm{d}}{\mathrm{d}t}(\dot R^2) = \frac{\mathrm{d}}{\mathrm{d}t}\left(\frac{8\pi G\rho r^2}{3} - k\right) \qquad (12.5.53)$$

Then we get:

$$2\dot R\ddot R = \frac{8\pi G}{3}\frac{\mathrm{d}}{\mathrm{d}t}(\rho R^2) = \frac{8\pi G}{3}\left(R^2\frac{\mathrm{d}\rho}{\mathrm{d}t} + \rho\frac{\mathrm{d}R^2}{\mathrm{d}t}\right) = \frac{8\pi G}{3}(R^2\dot\rho + 2\rho R\dot R) \qquad (12.5.54)$$

Let us inject:

$$\dot\rho = -3\left(\rho+\frac{P}{c^2}\right)\frac{\dot R}{R} \qquad (12.5.55)$$

in the relation:

$$2\dot R\ddot R = \frac{8\pi G}{3}(R^2\dot\rho + 2\rho R\dot R) \qquad (12.5.56)$$

Then we get:

$$2\dot R\ddot R = \frac{8\pi G}{3}\left(-3(\rho+\frac{P}{c^2}\frac{\dot R}{R}R^2 + 2\rho R\dot R\right) = \frac{8\pi G}{3}R\dot R\left(-3\left(\rho+\frac{P}{c^2}\right)+2\rho\right) \qquad (12.5.57)$$

Thus:

$$\frac{\ddot R}{R} = \frac{4\pi G}{3} = \left(-3\rho - 3\frac{P}{c^2} + 2\rho\right) = -\frac{4\pi G}{3}\left(\rho + 3\frac{P}{c^2}\right) \qquad (12.5.58)$$

The following relation:

$$\boxed{\frac{\ddot R}{R} = -\frac{4\pi G}{3}\left(\rho + 3\frac{P}{c^2}\right)} \qquad (12.5.59)$$

is the "Friedmann's second equation" that is also sometimes named "Raychaudhuri equation".

In general, in the field of cosmogony, any relation of the type $H^2 = (\dot R/R)^2 = \ldots$ is named "velocity equation" and any relation of the type $\ddot R/R = \ldots$ is named "acceleration equation".

Remark

Notice that when $\rho > 0$ and $P > 0$ we have that $\ddot{R} < 0$. This was the reason that had led Einstein to introduce his "cosmological term". Indeed, we see that otherwise we must have $\rho < -3P/c^2$ so that the right term remains positive...

12.5.2.1 Critical Density and Density parameters

Let us come back to our first Friedmann equation without cosmological constant. So we have shown above that:

$$H = \frac{1}{F}\mathrm{d}_t F \tag{12.5.60}$$

We obtained then by injecting the latter relation in the first Friedmann equation the following relation:

$$(\mathrm{d}_t F)^2 = \frac{8\pi G}{3}\rho F^2 - k \tag{12.5.61}$$

which rearranges with:

$$\rho = \rho_0 F^{-3} \tag{12.5.62}$$

into:

$$(\mathrm{d}_t F)^2 = \frac{8\pi}{3} G\rho_0 F^{-1} - k \tag{12.5.63}$$

The exponent of the left term requires that the right term is positive or zero as:

$$\frac{8\pi}{3} G\rho_0 F^{-1} \geq k \tag{12.5.64}$$

Let us recall that the initial conditions impose us that at time $t_0 = 0$ we have:

$$F(t_0) = 1 \quad \text{and} \quad \mathrm{d}_t F(t)|_{t=t_0} = H(t_0) \tag{12.5.65}$$

Indeed:

$$H(t_0) = \frac{1}{F(t_0)}\mathrm{d}_t F|_0 = \mathrm{d}_t F|_0 \tag{12.5.66}$$

Then it comes:

$$k = \frac{8\pi}{3} G\rho_0 - H_0^2 \tag{12.5.67}$$

This term should be accessible to observation, sadly H_0^2 is very poorly known and ρ_0 even more. In other words, given the "$-$" sign in the expression of k, we do not even know today the sign of this constant.

However, it may be important to notice that there is a value ρ_0 named "critical density" that cancels the k above and therefore also (see above):

$$\frac{-2k_1}{mr_0^2} \tag{12.5.68}$$

as it is also equal to k. This imply that the total energy of the Universe would be zero (following considerations of quantum cosmology).

This value ρ_0 is given immediately by:

$$\boxed{\rho_0 = \frac{3H_0^2}{8\pi G} = \rho_c} \qquad (12.5.69)$$

For $H_0 = 67.80 \pm 0.7\,[\text{km} \cdot \text{s}^{-1} \cdot \text{Mpc}^{-1}]$ we get:

$$\rho_0 \cong 8.66 \cdot 10^{-27}\,[\text{kg} \cdot \text{m}^{-3}] \qquad (12.5.70)$$

In comparison, a hydrogen atom weighs $1.7 \cdot 10^{-27}$ [kg], the critical density would therefore correspond to six hydrogen atoms per cubic meter.

Physicists have defined a constant (time-varying... so therefore not so constant...) denoted by the Greek letter Ω and named "cosmological density parameter" and given by the ratio of the mass density (or energy densities since the ratio will be the same!):

$$\Omega = \frac{\rho}{\rho_0} \qquad (12.5.71)$$

Astrophysicists often break the cosmological density parameter into three terms (notice the lower case indexes!):

$$\Omega = \Omega_{\text{matter}} + \Omega_{\text{radiation}} + \Omega_{\text{vacuum}} = \Omega_m + \Omega_r + \Omega_\Lambda \qquad (12.5.72)$$

estimated experimentally in this early 121st century (holocene calendar) at $\Omega = 1.003 \pm 0.004$. We can even found decomposition in more terms (radiation, relativistic matter, non-relativistic matter, dark energy, dark matter[59] and vacuum, etc.) like illustrated in the table below (the year is given according to the holocene calendar):

Species		**Hinshaw et al. (12012)**
Dark energy (Λ)	Ω_Λ	0.72 ± 0.01
Non-baryonic cold dark matter (CDM)	Ω_c	0.24 ± 0.01
Baryonic matter	Ω_b	0.047 ± 0.002
Neutrinos	Ω_ν	< 0.02
Photons (CMB)	Ω_γ	$5 \cdot 10^{-5}$
Total	Ω	1.003 ± 0.004
Curvature	Ω_k	-0.003 ± 0.004

Table 12.23: **Cosmic inventory**

Remark

When combined with other astrophysical data, particularly geometrical measurements of baryon acoustic oscillations, the Universe is constrained to be spatially flat (i.e. hence infinite in size) with $\Omega_k = 0.0004 \pm 0.0018$ - with a precision of around 2σ (95%) at the day we write these lines therefore not enough to conclude anything beyond reasonable doubt - in agreement with the 12018 results (holocene calendar) of the Planck team!

---

[59] Since June 12025 (holocene calendar) it is known thanks to FRB (Fast Radio Bursts) that approximately 76% of the Universe's baryonic matter lies in the IGM (InterGalactic Medium). About 15% resides in galaxy halos, and a small fraction is burrowed in stars or amid cold galactic galactic gas ([109]).

If one think the universe is Euclidean, the number of possible shapes shrinks dramatically. In 11934 (holocene calendar), Werner Nowacki proved that there are only 18 possible Euclidean 3-manifolds (see [420]). W. Hantschze and H. Wendt also published (see [228]) a more direct classification in 11935 (holocene calendar). Instead of an infinite list of 3-manifolds, we need only consider 18 possibilities for the spatial universe. Understanding the properties and appearances of these manifolds may supply the information needed to determine experimentally the universe's shape.

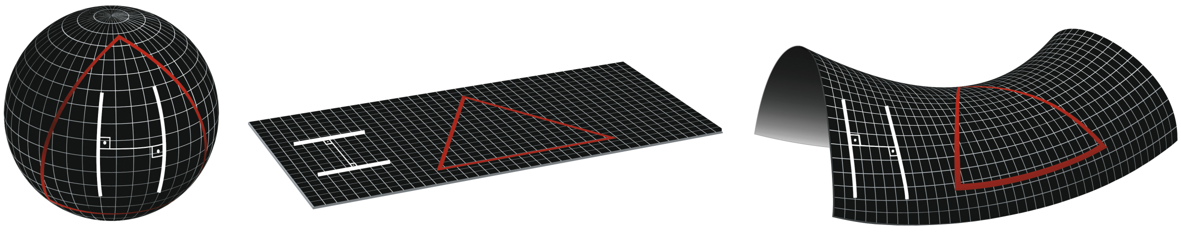
It is interesting to work with this constant Ω because in the case where:

- $\Omega = 1$ (i.e. $\rho = \rho_0$)
  We have therefore:
  $$\rho_0 = \rho_c = \frac{3H_0^2}{8\pi G} \tag{12.5.73}$$
  which gives by replacing that in the Friedmann equation above, the value $k = 0$ (flat and infinite Universe as we will see in our study of the relativistic model later below).

- $\Omega > 1$ (i.e. $\rho_0 > \rho_c$)
  By performing the same reasoning, and still using inequality, we have then: $k > 0$ (a Universe with positive curvature (closed) as we shall see in our study of the relativistic model).

- $\Omega < 1$ (i.e. $\rho_0 < \rho_c$)
  By performing the same reasoning, and still using inequality, we have then: $k < 0$ (a Universe with negative curvature (open) as we shall see in our study of the relativistic model).

These three situations can be summarized geometrically by the following well known figure:



Positive curvature
(spherical like/elliptic)
Closed (finite) Universe
$\Omega > 1, \rho_0 > \rho_c$
Big Crunch end

Flat (zero) curvature
(plane like/euclidian)
Flat (infinite) Universe
$\Omega = 1, \rho_0 = \rho_c$

Negative curvature
(horse's saddle like/hyperbolic)
Opened (infinite) Universe
$\Omega < 1, \rho_0 < \rho_c$
Cold Death end

Figure 12.256: **Illustration of the different types of universes (source: NASA / WMAP Science Team)**

Advanced theoretical physics seems to be able to prove (see [169]) that our Universe can have only eighteen possible topologies given by:

Symbol	**Name**	**Compact Dimension**	**Orientable**	**Homogeneous**	**Isotropic**
E_1	3-torus (flat and finite)	3	Yes	Yes	No
E_2	Half-turn	3	Yes	No	No
E_3	Quarter-turn	3	Yes	No	No
E_4	Third-turn	3	Yes	No	No
E_5	Sixth-turn	3	Yes	No	No
E_6	Hantzsch-Wendth	3	Yes	No	No
E_7	Klein space	3	No	No	No
E_8	- (horizontal flip)	3	No	No	No
E_9	- (vertical flip)	3	No	No	No
E_{10}	- (half-turn)	3	No	No	No
E_{11}	Chimney space	2	Yes	Yes	No
E_{12}	- (half turn)	2	Yes	No	No
E_{13}	- (vertical flip)	2	No	No	No
E_{14}	- (horizontal flip)	2	No	No	No
E_{15}	- (half turn + flip)	2	No	No	No
$E_{16}^{(h)}$	Slab (unrotated)	1	Yes	Yes	No
$E_{16}^{(i)}$	Slab (rotated)	1	Yes	No	No
E_{18}	Covering space	0	Yes	Yes	Yes

Table 12.24: **Possible topologies of our Universe (cosmic topologies)**

All measurement which have been made so far have failed to show a curvature of the Universe (anisotropy). The measurements of the microwave background (see mathematical details further below) by the BOOMERANG balloon and COBE satellite however, tend to support the hypothesis of a relatively flat Universe validating therefore numerical simulations[60]:

---

[60] We will show in the future that the mathematics of the CMB involve spherical harmonics and Fourier transform on a sphere.

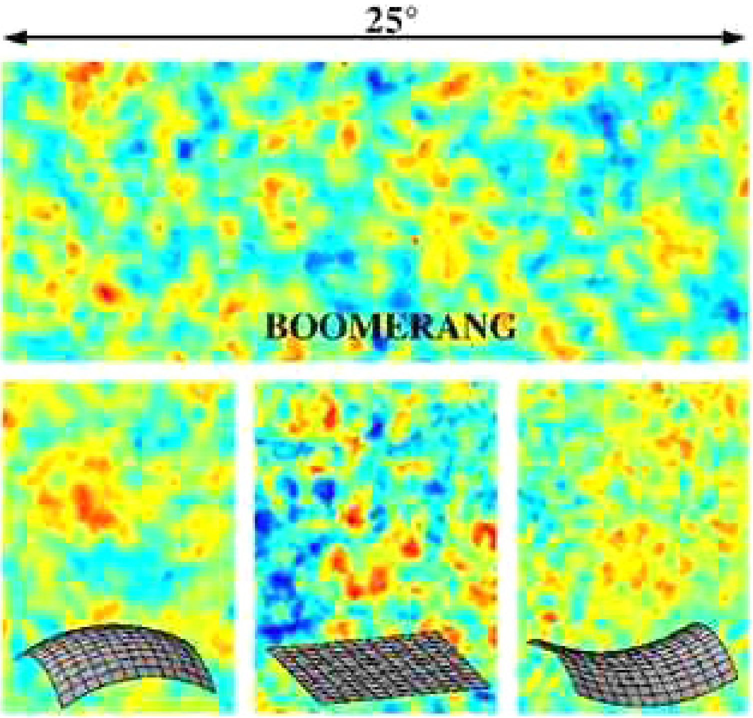


Figure 12.257: **Illustration of what would give observations depending on the curvature type**

As we can see in the figure below satellites sensibility increase and permits to validate or invalidate speculative models with more and more confidence:

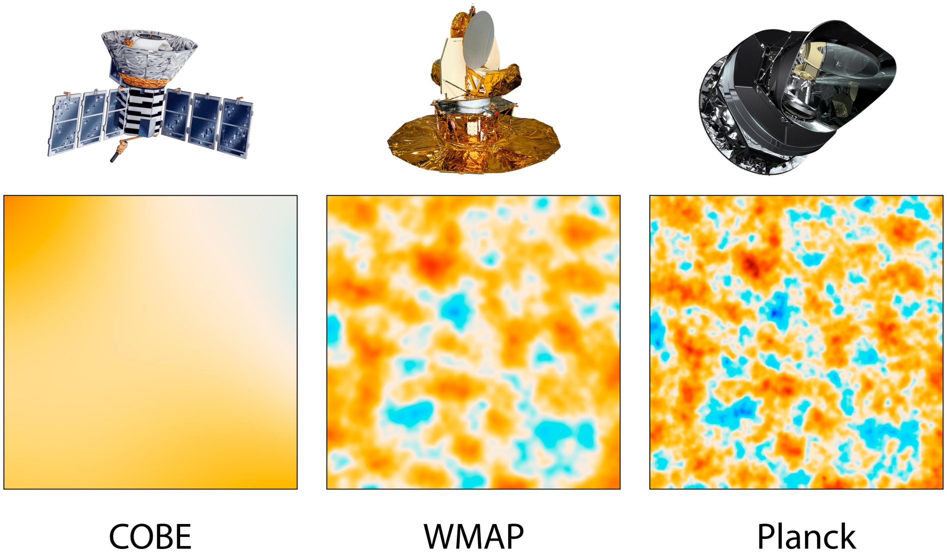

Figure 12.258: **Comparison of CMB results from COBE, WMAP and Planck – 12013-03-21 (source: Wikipedia)**

The Planck CMB seems to give evidence of fluctuations on the order of 1 part in $100,000$ across the sky (root mean square variations are only $18\,[\mu\text{K}]$). So according to some cosmologist this may be an evidence that the Universe was quite homogeneous at its beginning (hence the use of the Friedmann-Robertson-Walker-Lemaître metric - among others - in many Quantum Cosmology models).

And an another interesting figure that shows our Universe density fluctuations at different scales:

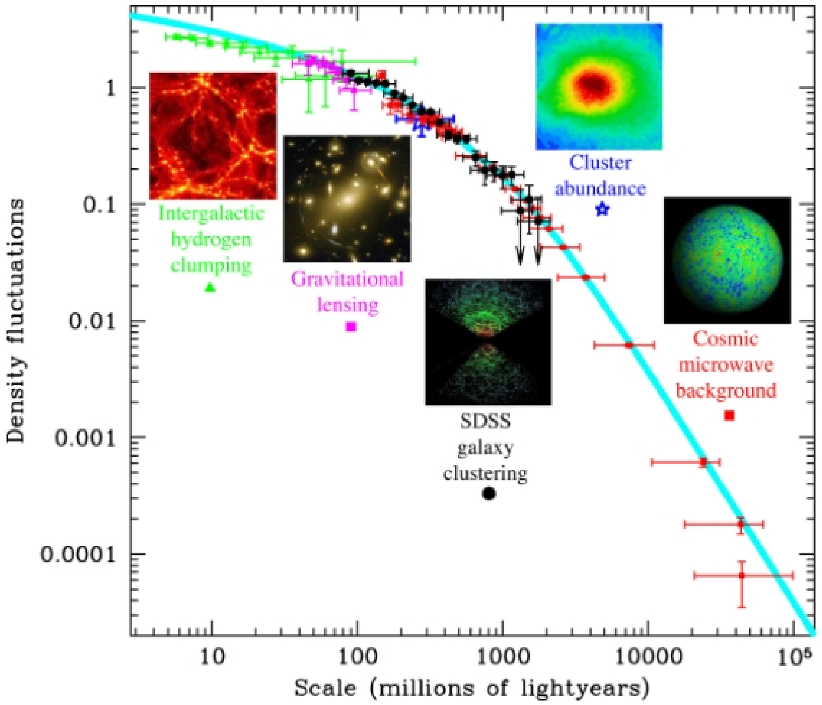

Figure 12.259: **Universe fluctuation density scales (source: ?)**

Now remember that we have proved earlier that:

$$H^2 = \frac{8\pi G}{3}\rho - kF^{-2} \tag{12.5.74}$$

Rearranging:

$$1 = \frac{8\pi G}{3H^2}\rho - \frac{k}{(FH)^2} \tag{12.5.75}$$

Then according to what we have defined just above the relation can be rewritten:

$$1 = \Omega_m + \Omega_k \tag{12.5.76}$$

where:

$$\Omega_m := \frac{8\pi G\rho}{3H^2} \qquad \Omega_k := -\frac{k}{(FH)^2} \tag{12.5.77}$$

That are other well known density parameters in cosmology!

Remark

The concept of Universe topology and openness are actually normally two separate concepts. When we speak of "open" or "closed" Universe we do not normally talk about its topology but its destiny! Thus, an "open" Universe is expanding indefinitely and a "closed" Universe recontracts on itself after a given time. That said, in the models that we study in this section (cosmological constant equal to zero), the curvature is directly related to the density, and thus to its openness.

Let us come back to the relation:

$$(\mathrm{d}_t F)^2 = \frac{8\pi}{3} G\rho_0 F^{-1} - k \tag{12.5.78}$$

We can write:

$$\mathrm{d}_t F(t) = \sqrt{\frac{A}{F} - k} \tag{12.5.79}$$

By adopting the notation:

$$A = \frac{8\pi}{3} G\rho_0 \tag{12.5.80}$$

Remark

The actual measurement give (year 12007 according to holocene calendar): $A \cong 0.2793923067 \cdot 10^{-35}$.

Therefore:

$$\mathrm{d}F(t) = \pm\sqrt{\frac{A}{F} - k}\mathrm{d}t \tag{12.5.81}$$

It is now appropriate for us to consider three situations:

$$k = 0 \qquad k < 0 \qquad k > 0 \tag{12.5.82}$$

thus corresponing respectively to the following cosmological density parameters:

$$\Omega = 1 \qquad \Omega < 0 \qquad \Omega > 0 \tag{12.5.83}$$

i.e. positive curvature: $k = +1, \Omega_k < 0, \Omega > 1$, negative curvature: $k = -1, \Omega_k > 0$, $\Omega < 1$, zero curvature: $k = 0, \Omega_k = 0, \Omega = 1$).

Remark

We can't put $\rho_0 = 0$ because our initial assumption was the principle of conservation of energy.

Let us now introduce the same cosmological density parameters but with a slightly different approach (it's better for the reader the see the both approach). Again, let us consider the first Friedmann equation considering the following notation:

$$\left(\frac{\dot{a}}{a}\right)^2 + \frac{k}{a^2} = \frac{8\pi}{3} G\rho \tag{12.5.84}$$

We recall that:

$$H(t) := \frac{\dot{a}}{a} \tag{12.5.85}$$

and that we can formally associate an energy density with the cosmological constant:

$$\rho_\Lambda := \frac{\Lambda}{8\pi G} \tag{12.5.86}$$

With this notation we can re-write Friedmann equation:

$$H^2 + \frac{k}{a^2} = \frac{8\pi G}{3}\left(\sum_i \rho_i + \rho_\Lambda\right) \tag{12.5.87}$$

If the geometry of the universe is flat, $k=0$, and therefore:

$$\rho_{\text{tot}} := \sum_i \rho_i + \rho_\Lambda = \frac{3H^2}{8\pi G} \equiv \rho_{\text{crit}} \tag{12.5.88}$$

which we can use to define the fraction of the critical density contributed by each component of the Universe:

$$\Omega_i := \frac{\rho_i}{\rho_{\text{crit}}} \tag{12.5.89}$$

Thanks to this definition:

$$H^2 + \frac{k}{a^2} = \frac{8\pi G}{3}\left(\sum_i \rho_i + \rho_\Lambda\right) \tag{12.5.90}$$

Can be rewritten as:

$$\frac{k}{a^2H^2} = \sum_i \Omega_i + \Omega_\Lambda - 1 \tag{12.5.91}$$

and we can do even better by defining:

$$\Omega_k := -\frac{k}{(aH)^2} \tag{12.5.92}$$

which then leads to the elegant result:

$$\sum_i \Omega_i + \Omega_\Lambda + \Omega_k = 1 \tag{12.5.93}$$

12.5.3 Friedmann-Lemaître Euclidean Cosmological Models

The Euclidean cosmological models of Friedmann-Lemaître consist in the Newtonian limit to study the "fundamental equation of Friedmann models":

$$\boxed{\mathrm{d}F(t)=\pm\sqrt{\frac{A}{F}-k}\mathrm{d}t} \qquad (12.5.94)$$

considering the three situations:

$$k=0 \qquad k<0 \qquad k>0 \qquad (12.5.95)$$

Remark

It is possible within the framework of General Relativity to rigorously find a solution to the Einstein's field equations named the "Friedmann-Lemaître-Robertson-Walker metric" which in the case of a Newtonian approximation gives us the Friedmann equations obtained in the present text (often these are the approximations that are used in the literature because the exact solution is out of the framework of the traditional universities courses of the 121st century according to the holocene calendar). For the general treatment see further below page 5987.

12.5.3.1 Flat spaces ($k=0$)

The flat (Euclidean) space model consist to assume that $k=0$. In other words, we are in a Universe whose density is named "critical density" or also simply "flat" (as we will see with the relativistic model).

Then we have the following equation:

$$\mathrm{d}F(t)=\pm\sqrt{\frac{A}{F}-k}\mathrm{d}t=\pm\sqrt{\frac{A}{F}}\mathrm{d}t \qquad (12.5.96)$$

By arranging appropriately the terms:

$$\sqrt{F}\mathrm{d}F(t)=\pm\sqrt{A}\mathrm{d}t \qquad (12.5.97)$$

and by integrating, it comes (there is obviously a constant of integration that we will add at the end!):

$$\int\sqrt{F}\mathrm{d}F(t)=\pm\sqrt{A}t=\pm\sqrt{\frac{8\pi G\rho_0}{3}}t \qquad (12.5.98)$$

Which simplifies in (we raise to the square, hence the removal of the double sign ±):

$$F^3=6\pi rG\rho_0t^2 \qquad (12.5.99)$$

So we have in this model the relation:

$$F=\sqrt[3]{6\pi rG\rho_0}t^{2/3} \qquad (12.5.100)$$

to which we must add now the constant of integration for the condition corresponding to today:

$$F(t_0)=F(0)=1 \tag{12.5.101}$$

that remains satisfied. Therefore:

$$F=\sqrt[3]{6\pi r G\rho_0}t^{2/3}+1 \tag{12.5.102}$$

This gives us a plot function that looks like this (do not trust the values shown on the horizontal axis as they are arbitrary):

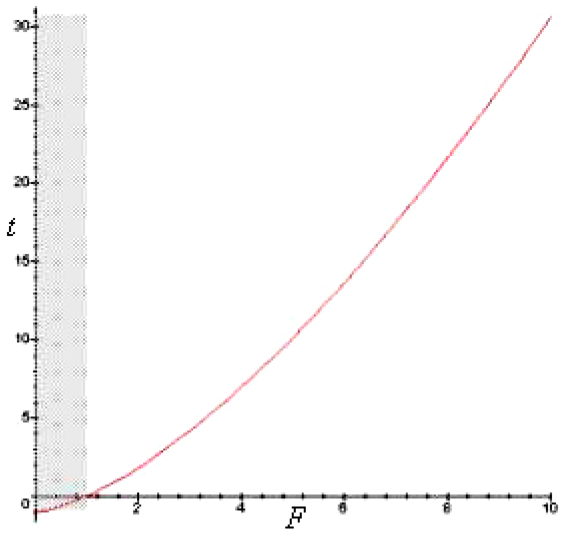

Figure 12.260: **Evolution of the scale factor for a zero curvature space**

We put the area where $F(t)<1$ in evidence to remember that this part of the solution is to reject.

So we have a model of Universe in which the scale factor is growing exponentially and this indefinitely.

Notice also that in this case:

$$\lim_{t\to 0}F(t)=1 \tag{12.5.103}$$

That means with this model that the Universe had already a non-zero size at the beginning of time. This is a good point as we have already presented at the beginning that we should have $F(t)\in\mathbb{R}^+\backslash\{0\}$.

Remark

More ρ_0 is big, more the scale factor increase fast (meaning that the slope is obviously larger).

12.5.3.1.1 Flat space dominated by matter

There is also another approach much more elegant and subtle from my point of view than the previous proof (I have discovered that many years after writing the previous version). It has the benefit of highlighting a hypothesis that does not appear with previous developments.

We start from the first Friedmann equation:

$$\left(\frac{R'}{R}\right)^2=\frac{8\pi G\rho}{3}-\frac{k}{R^2} \tag{12.5.104}$$

Putting k as being equal to zero and using the trick that consist to start from the relation proved also earlier above (used to proved the second Friedmann equation):

$$\dot{\rho}=-3\left(\rho+\frac{P}{c^2}\right)\frac{\dot{R}}{R} \tag{12.5.105}$$

to require that the fluid pressure P (whatever it is: gas or radiation) is zero. We then say that the Universe is a universe dominated by matter and we deduce:

$$\dot{\rho}+3\rho\frac{R'}{R}=0 \tag{12.5.106}$$

which gives us (in this situation ρ is often denoted ρ_{mat} in many textbooks):

$$R^3\dot{\rho}+3\rho R^2R'=0\Rightarrow\frac{\mathrm{d}}{\mathrm{d}t}(R^3\rho)=0 \tag{12.5.107}$$

Hence the important relation for matter dominated Universe:

$$\boxed{R^3\rho=R_0^3\rho_0=c^{te}} \tag{12.5.108}$$

Under these conditions, the first Friedmann equation becomes:

$$\frac{\mathrm{d}R}{R}=\sqrt{\frac{8\pi G\left(\rho_0\dfrac{R_0^3}{R^3}\right)}{3}}\mathrm{d}t \tag{12.5.109}$$

rearranging and simplifying, we then have:

$$\int R^{1/2}\mathrm{d}R=\int\sqrt{\frac{8\pi G\rho_0R_0^3}{3}}\mathrm{d}t \tag{12.5.110}$$

which gives:

$$\frac{2}{3}R^{3/2}+c^{te}=\sqrt{\frac{8\pi G\rho_0R_0^3}{3}}t \tag{12.5.111}$$

At the time $t=0$ of the "Big Bang", many textbooks assume the scale factor is equal to $R=0$ (only in the purpose to simplify the notations!!!) and thus the constant is zero (don't forget that in reality we should rather assume that it is equal to $-3/2$ instead to have after rearranging a $+1$ on the right side of the equality when $t=0$). Then we have:

$$R(t)=(6\pi G\rho_0R_0^3)^{1/3}t^{2/3}=\left(6\pi G\frac{3H_0^2}{8\pi G}R_0^3\right)^{1/3}t^{2/3}=\left(\frac{9H_0^2}{4}R_0^3\right)^{1/3}t^{2/3} \tag{12.5.112}$$

By putting that at time $t=0$, the scaling factor R_0 was unitary, the latter relation simplifies to:

$$R(t)=\left(\frac{9H_0^2}{4}\right)^{1/3}t^{2/3}=\left(\frac{9}{4}\right)^{1/3}(H_0t)^{2/3} \tag{12.5.113}$$

Using the common notation in theoretical cosmology we get the famous relation often given without proof:

$$\boxed{a(t)\propto t^{2/3}} \tag{12.5.114}$$

Notice also that in this case, with this simplified notation (that doesn't take into account the integration constant), we have the misleading limit:

$$\lim_{t\to 0}a(t)=0 \tag{12.5.115}$$

But in fact, if we take into consideration the constant, we have indeed:

$$\lim_{t\to 0}a(t)=1 \tag{12.5.116}$$

that means (for recall) that at beginning of the time, the Universe didn't have zero dimensions (otherwise applying a non-null scale factor on a zero value wouldn't have any effect), but had already a given unknown size.

If we assume that the scale factor is today taken as unitary, then it comes:

$$t=\frac{2}{3H_0} \tag{12.5.117}$$

and by replacing in it the numerical values currently known of the Hubble parameter, it follows that the universe is now aged about 8.6 billion years (compared to 13 billion of the Hubble time obtained earlier above!).

12.5.3.1.2 Flat space dominated by radiation

We have proved in the section of Thermodynamics during our study of the Stefan-Boltzmann law (see page 3710) that the pressure of radiation was related to the energy density by the following equation:

$$P=\frac{1}{3}\rho_E \tag{12.5.118}$$

Remark

In many textbooks the authors define:

$$P=\frac{\gamma}{3}\quad\text{with: }\gamma=\begin{cases}1 & \text{radiation}\\ 0 & \text{matter (dust)}\end{cases} \tag{12.5.119}$$

In a universe dominated by radiation, the relation:

$$\dot{\rho}=-3\left(\rho+\frac{P}{c^2}\right)\frac{\dot{R}}{R} \tag{12.5.120}$$

proved earlier, expressed with a density of energy and not a density of mass becomes:

$$\dot{\rho}c^2=-3\left(\rho c^2+\frac{Pc^2}{c^2}\right)\frac{\dot{R}}{R} \tag{12.5.121}$$

Therefore:

$$\dot{\rho}_E=-3\left(\rho_E+P\right)\frac{\dot{R}}{R} \tag{12.5.122}$$

and using the relation between radiation pressure and energy density, we get:

$$\dot{\rho}_E=-3\left(\rho_E+\frac{\rho_E}{3}\right)\frac{\dot{R}}{R} \tag{12.5.123}$$

After a little rearrangement, we get:

$$\dot{\rho}_E+4\rho_E\frac{\dot{R}}{R}=0 \tag{12.5.124}$$

from which we get that:

$$\dot{\rho}_E+4\rho_E\frac{\dot{R}}{R}=0\Rightarrow R^4\dot{\rho}_E+4\rho_E\dot{R}R^3=0\Rightarrow\frac{\mathrm{d}}{\mathrm{d}t}\left(R^4\rho_E\right)=0\Rightarrow R^4\rho_E=R_0^4\rho_{E,0}=c^{te} \tag{12.5.125}$$

Hence the important relation for radiation dominated Universe:

$$\boxed{R^4\rho_E=R_0^4\rho_{E,0}=c^{te}} \tag{12.5.126}$$

Remark

Using the previous results notice that we have so far:

$$R^n\rho=R_0^n\rho_0\Rightarrow\begin{cases}n=0\text{ for vacuum}\\ n=3\text{ for matter dominated Universe}\\ n=4\text{ for radiation dominated Universe}\end{cases} \tag{12.5.127}$$

Under these conditions, the first Friedmann equation:

$$\left(\frac{R'}{R}\right)^2=\frac{8\pi G\rho}{3}-\frac{k}{R^2} \tag{12.5.128}$$

becomes first by changing into energy density and with k being put as equal to zero:

$$\left(\frac{\dot{R}}{R}\right)^2=\frac{8\pi G\rho_E}{3c^2} \tag{12.5.129}$$

and so we can replace the energy density by the result we get just before:

$$\left(\frac{\dot{R}}{R}\right)^2=\frac{8\pi G\rho_{E,0}}{3c^2}\left(\frac{R_0}{R}\right)^4 \tag{12.5.130}$$

Remark

The prior-previous relation is often denoted:

$$3H^2M_{\text{P}}^2=\rho \quad (12.5.131)$$

where:

$$M_{\text{P}}=\frac{1}{\sqrt{8\pi G}} \quad (12.5.132)$$

is sadly (because it hasn't the units of a mass and it's not related to the different famous Planck values) named the "reduced Planck mass".

Then we have:

$$\frac{\mathrm{d}R}{\mathrm{d}t}=\sqrt{\frac{8\pi G\rho_{E,0}R_0^4}{3c^2}}\frac{1}{R} \quad (12.5.133)$$

hence:

$$R\mathrm{d}R=\sqrt{\frac{8\pi G\rho_{E,0}R_0^4}{3c^2}}\mathrm{d}t \quad (12.5.134)$$

The primitive is obvious and immediate:

$$\frac{R^2}{2}+c^{te}=\sqrt{\frac{8\pi G\rho_{E,0}R_0^4}{3c^2}}t \quad (12.5.135)$$

At the time $t=0$ of the "Big Bang", many textbooks assume the scale factor is equal to $R=0$ (only in the purpose to simplify the notations!!!) and thus the constant is zero (don't forget that in reality we should rather assume that it as equal to -2 instead to have after rearranging a $+1$ on the right side of the equality when $t=0$). Then we have:

$$\frac{R^2}{2}=\sqrt{\frac{8\pi G\rho_{E,0}R_0^4}{3c^2}}t \quad (12.5.136)$$

But assuming that at $t=0$ we had $R_0=1$ then we have:

$$\frac{R^2}{2}=\sqrt{\frac{8\pi G\rho_{E,0}}{3c^2}}t \quad (12.5.137)$$

Therefore:

$$R=\left(\frac{32\pi G\rho_{E,0}}{3c^2}\right)^{1/4}t^{1/2}=\left(\frac{32\pi G}{3}\rho_0\right)^{1/4}t^{1/2}=\left(\frac{32\pi G}{3}\frac{3H_0^2}{8\pi G}\right)^{1/4}t^{1/2} \quad (12.5.138)$$

Thus after simplification it remains only:

$$R(t)=(4H_0)^{1/2}t^{1/2} \quad (12.5.139)$$

Using the common notation in theoretical cosmology we get the famous relation often given without proof:

$$\boxed{a(t)\propto t^{1/2}} \quad (12.5.140)$$

Then a flat universe dominated by radiation has a scaling factor that is growing slightly more slowly than a flat universe dominated by matter.

Notice also that in this case:

$$\lim_{t\to 0} a(t)=0 \tag{12.5.141}$$

But in fact, if we take into consideration the integration constant, we have indeed:

$$\lim_{t\to 0} a(t)=1 \tag{12.5.142}$$

that means (for recall) that at beginning of the time, the Universe didn't have zero dimensions (otherwise applying a non-null scale factor on a zero value wouldn't have any effect), but had already a given unknown size.

In comparison with Maple™ 4.00b (blue: flat universe dominated by matter, in red: flat universe dominated by radiation):

```
>plot([t^(2/3),t^(1/2)],t=0..2*Pi,0..3,color=[blue,red]);
```

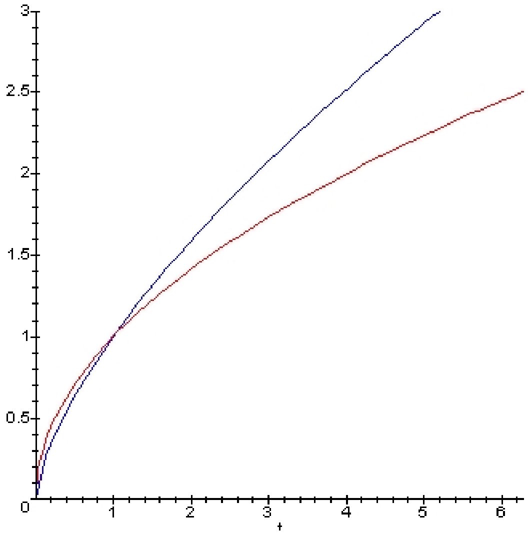

Figure 12.261: Evolution of R for a zero curvature space dominated by matter or radiation

12.5.3.1.2.1 Standard form of the Friedmann equation

We have seen that for a universe dominated by matter we had:

$$\dot{\rho}=-3\left(\rho+\frac{P}{c^2}\right)\frac{\dot{R}}{R} \tag{12.5.143}$$

that reduces to:

$$\dot{\rho}+3\rho\frac{\dot{R}}{R}=0 \tag{12.5.144}$$

and for a universe dominated by radiation:

$$\dot{\rho}_E+4\rho\frac{\dot{R}}{R}=0 \tag{12.5.145}$$

So we see that the two previous relations are respectively a special case of the first one that if we rewrite as:

$$\dot{\rho}=-3\left(\rho+\frac{\omega(T)\rho c^2}{c^2}\right)\frac{\dot{R}}{R}\Leftrightarrow\frac{\dot{\rho}}{\rho}=-3\left(1+\omega(T)\right)\frac{\dot{R}}{R}\Rightarrow \mathrm{d}\ln(\rho)=-3(1+\omega(T))\mathrm{d}\ln(R) \tag{12.5.146}$$

with $P=\omega(T)\rho c^2$, that is to say a barotropic fluid assumption (linear relation between ρ and P). We see that by introducing $\omega(T)$, named the "density parameter", we fall back on the first radiation one when $\omega(T)=1/3$ and collisionless matter when $\omega(T)=0$ and vacuum energy when $\omega(T)=-1$.

We also have by integrating the last relation above :

$$\int \mathrm{d}\ln(\rho)=-3(1+\omega(T))\int \mathrm{d}\ln(R)\Rightarrow\ln(\rho)=-3(1+\omega(T))\ln(R) \tag{12.5.147}$$

Hence (using elementary natural logarithm rules and properties):

$$\ln(\rho)=\ln\left(R^{-3(1+\omega(T))}\right) \tag{12.5.148}$$

And taking the exponential on both sides we have finally:

$$\rho(t)\propto R(t)^{-3(1+\omega(T))}\propto\begin{cases}R(t)^{-3} & \text{for } \omega(T)=0 \text{ (pressureless matter (i.e. dust))}\\ R(t)^{-4} & \text{for } \omega(T)=1/3 \text{ (radiation/ultra-relativistic matter)}\\ c^{te} & \text{for } \omega(T)=-1 \text{ (vacuum energy)}\end{cases} \tag{12.5.149}$$

Notice that we can often found in various textbooks and even in the present book, the following notation for the energy density (...):

$$\rho=A_\omega a^{-3(\omega+1)}\quad\text{or}\quad\rho_{\omega,0}=\rho_\omega\left(\frac{R}{R_0}\right)^{-3(\omega+1)} \tag{12.5.150}$$

with $\rho_{\omega,0}$ being the value of energy density at present time.

To be more exhaustive we have to summarize:

$P=\omega\rho$ (equation of state)		
ρ is diluated with expansion as $a^{-3(1+\omega)}$		
$\omega=0$	ρ dilutes as (because universe is made of matter): (this is the most intuitive case if you consider a cube of side L, if the side is multiplied by 2 the volume increases of a factor $2^3=8$ hence the energy density of matter is divided by 8)	a^3
$\omega=1/3$	ρ dilutes as (because universe is made of radiation/photons): (again considering the same cube but made this time of radiation if length is multiplied by 2 then the volume also increases of a factor $2^3=8$ but as the photon wavelength is also divided by 2 at the same time then the energy density of radiation is divided by $2\cdot 2^3=2^4$)	a^4
$\omega=-1/3$	ρ (the density energy) decrease but slower: (that means that density of object still decrease but is somehow compensated by an increase of the energy these same objects, i.e. the universe expansion accelerated slowly and indefinitely)	a^2
$\omega=1$	ρ (the density energy) remains constant: (that means energy is extracted from vacuum and we know this isn't an issue as the law of conservation of energy doesn't apply when space-time change)	0
$\omega<-1$	ρ (the density energy - named "phantom energy") increase: (that means that density of energy of vacuum strictly increase very fast and the universe will be ripped of in a finite time)	$a^{-\lvert c^{te}\rvert}$
Latest data still contradicts: 12018 Planck gives $\omega=-1.03\pm 0.03$ and 12023 by KIAS $\omega=-0.903\pm 0.023$		

Table 12.25: **Different scenario of density-pressure relation in General Relativity**

We are now in a position to determine the dynamical evolution of the Universe without cosmological constant. As we have seen, we need to use one of the Friedmann equations, plus the equations of state and continuity equation for each of the fluids in the Universe. Let's start from the first Friedmann equation:

$$\begin{aligned}\left(\frac{\dot{R}}{R}\right)^2+\frac{k}{R^2c^2}&=\frac{8\pi G}{3c^2}\rho\\ H^2+\frac{k}{R^2c^2}&=\frac{8\pi G}{3c^2}\rho\\ H^2\left(1-\frac{8\pi G}{3H^2c^2}\rho\right)&=-\frac{k}{R^2c^2}\end{aligned}\tag{12.5.151}$$

Here above $8\pi G/3H^2$ has the dimensions of an energy density, and is named as we already know it (see page 5897), the "critical density". As we have seen it, it is customary to express the energy densities in units of the critical density:

$$\rho_c(t):=\frac{8\pi G}{3c^2H^2}\qquad \Omega_i(t)=\frac{\rho_i(t)}{\rho_c(t)}\tag{12.5.152}$$

and so, we have:

$$\boxed{H^2(1-\Omega(t))=-\frac{k}{R^2c^2}} \tag{12.5.153}$$

We see that there is a direct connection between the critical energy density and the geometry of the Universe, as the curvature will be respectively positive, zero or negative if $\Omega>1,\Omega=1$ or $\Omega<1$ respectively.

Today, we have:

$$H_0^2\left(1-\Omega_0\right)=-\frac{k}{R_0^2c^2} \tag{12.5.154}$$

so, we have an expression of the curvature as a function of H_0 and the total density today.

Starting from:

$$H^2=\frac{8\pi G}{3c^2}\left(\rho_m+\rho_r+\rho_X\right)-\frac{k}{R^2c^2} \tag{12.5.155}$$

where ρ_X is the energy density of dark matter[61], we can substitute the value of k and the evolutions of the densities of the various fluids obtained just earlier and the Cosmological redshift (see page 5994) to get:

$$\begin{aligned}
H^2&=\frac{8\pi G}{3c^2}\left(\rho_m+\rho_r+\rho_X\right)-\frac{k}{R_0^2c^2}\frac{R_0^2}{R^2}\\
&=\frac{8\pi G}{3c^2}\left(\rho_{m,0}\left(\frac{R_0}{R}\right)^3+\rho_{r,0}\left(\frac{R_0}{R}\right)^4+\rho_X\left(\frac{R_0}{R}\right)^{3(1+\omega_X)}\right)+H_0^2\left(1-\Omega_0\right)\left(\frac{R_0}{R}\right)^2\\
&=\frac{8\pi G}{3c^2}\frac{H_0^2}{H_0^2}\left(\rho_{m,0}\left(\frac{R_0}{R}\right)^3+\rho_{r,0}\left(\frac{R_0}{R}\right)^4+\rho_X\left(\frac{R_0}{R}\right)^{3(1+\omega_X)}\right)+H_0^2\left(1-\Omega_0\right)\left(\frac{R_0}{R}\right)^2\\
&=\frac{8\pi G}{3c^2H_0^2}H_0^2\left(\rho_{m,0}\left(\frac{R_0}{R}\right)^3+\rho_{r,0}\left(\frac{R_0}{R}\right)^4+\rho_X\left(\frac{R_0}{R}\right)^{3(1+\omega_X)}\right)+H_0^2\left(1-\Omega_0\right)\left(\frac{R_0}{R}\right)^2\\
&=\frac{1}{\rho_c}H_0^2\left(\rho_{m,0}\left(\frac{R_0}{R}\right)^3+\rho_{r,0}\left(\frac{R_0}{R}\right)^4+\rho_X\left(\frac{R_0}{R}\right)^{3(1+\omega_X)}\right)+H_0^2\left(1-\Omega_0\right)\left(\frac{R_0}{R}\right)^2\\
&=H_0^2\left(\frac{\rho_{m,0}}{\rho_c}\left(\frac{R_0}{R}\right)^3+\frac{\rho_{r,0}}{\rho_c}\left(\frac{R_0}{R}\right)^4+\frac{\rho_X}{\rho_c}\left(\frac{R_0}{R}\right)^{3(1+\omega_X)}\right)+H_0^2\left(1-\Omega_0\right)\left(\frac{R_0}{R}\right)^2\\
&\cong H_0^2\left(\Omega_{m,0}(1+z)^3+\Omega_{r,0}(1+z)^4+\Omega_{X,0}(1+z)^{3(1+w_X)}+\left(1-\Omega_0\right)(1+z)^2\right)
\end{aligned} \tag{12.5.156}$$

This is the "standard form of the Friedmann equation" use by some authors of textbooks on General Relativity, which connects the evolution of the Hubble parameter $H(z)$ with the densities today. We generally drop the ' 0 ' subscripts, and define $\Omega_k=1-\Omega_0$ (Ω_k is not an actual mass/energy density and is defined as $\Omega_k = 1 - \Omega_0$ so that $\Omega_k = 0$ for a spatially flat universe), which gives:

---

[61] Since June 12025 (holocene calendar) it is known thanks to FRB (Fast Radio Bursts) that approximately 76% of the Universe's baryonic matter lies in the IGM (InterGalactic Medium). About 15% resides in galaxy halos, and a small fraction is burrowed in stars or amid cold galactic galactic gas ([109]).

$$\boxed{H(z) \cong H_0 \left[\Omega_m (1+z)^3 + \Omega_r (1+z)^4 + \Omega_X (1+z)^{3(1+w)} + \Omega_k (1+z)^2\right]^{1/2}} \quad (12.5.157)$$

So we have a prediction for $H(z)$ as a function of the matter, radiation and dark energy densities today, we have a good idea of how these densities evolve with z. And above all, we can use the expression of $H(z)$ above to compute distances, in other terms, we can connect the evolution of cosmic expansion to quantities which can all be observed.

When the energy densities are dominated by one single component, it is quite easy to integrate the Friedmann standard equation and get the evolution of a as a function of cosmic time.

Let's define :

$$x := \frac{a}{a_0} \cong \frac{1}{1+z} \quad (12.5.158)$$

Then, the Friedmann equation can be rewritten:

$$\frac{\mathrm{d}x}{\mathrm{d}t} \cong H_0 \left(\Omega_m / x^3 + \Omega_r / x^4 + \Omega_X / x^{3(1+\omega)} + \Omega_k / x^2\right)^{1/2} \quad (12.5.159)$$

as often the convention $a_0 = 1$ is used we can found the latter relation in the following shape too (the terms are rearranged in ascending negative power):

$$H(a) = \frac{\mathrm{d}x}{\mathrm{d}t} = \dot{a} \cong H_0 \sqrt{\Omega_r a^{-4} + \Omega_m a^{-3} + \Omega_k a^{-2} + \Omega_X a^{-3(1+\omega)}} \quad (12.5.160)$$

The latter is also commonly written (if we don't trop de '0' we have dropped earlier before):

$$H(a) \cong H_0 \sqrt{\Omega_{r,0} a^{-4} + \Omega_{m,0} a^{-3} + \Omega_{k,0} a^{-2} + \Omega_{X,0} a^{-3(1+\omega)}} \quad (12.5.161)$$

That last term inside the parenthesis is often taken as the dark energy! Assuming the latter remains constant (i.e. $\rho_\Lambda = \rho_{\Lambda,0} ...$ and hence we don't take its general form named "quintessence"):

$$H(a) \cong H_0 \sqrt{\Omega_{r,0} a^{-4} + \Omega_{m,0} a^{-3} + \Omega_{k,0} a^{-2} + \Omega_{\Lambda,0}} \quad (12.5.162)$$

The letters are also often capitalized such that:

$$H(a) \cong H_0 \sqrt{\Omega_{R,0} a^{-4} + \Omega_{M,0} a^{-3} + \Omega_{k,0} a^{-2} + \Omega_{\Lambda,0}} \quad (12.5.163)$$

The latest values of the parameters, obtained from the Planck mission, are:

$$\begin{gathered} H_0 = 67.3\,[\,\text{km}\cdot\ \text{s}^{-1}\cdot \text{Mpc}^{-1}] \\ \Omega_{R,0} = 9.24 \cdot 10^{-5}, \quad \Omega_{M,0} = 0.315 \\ \Omega_{\Lambda,0} = 0.685, \quad \Omega_{k,0} = 0 \end{gathered}$$

So now we have the Hubble parameter as a function of the scale radius a. How can we convert this into a function of time? From:

$$\dot{a} = \frac{\mathrm{d}a}{\mathrm{d}t} \quad (12.5.164)$$

we get:

$$\mathrm{d}t=\frac{\mathrm{d}a}{\dot{a}}=\frac{\mathrm{d}a}{aH(a)}=\frac{a\,\mathrm{d}a}{a^2H(a)} \tag{12.5.165}$$

so that:

$$t(a)=\int_0^a\frac{a'\mathrm{d}a'}{a'^2H(a')}=\frac{1}{H_0}\int_0^a\frac{a'\mathrm{d}a'}{\sqrt{\Omega_{R,0}+\Omega_{M,0}a'+\Omega_{k,0}a'^2+\Omega_{\Lambda,0}a'^4}} \tag{12.5.166}$$

Finally we have for the age of our universe:

$$\boxed{t(a)\cong\frac{1}{H_0}\int_0^a\frac{a'\mathrm{d}a'}{\sqrt{\Omega_{R,0}+\Omega_{M,0}a'+\Omega_{k,0}a'^2+\Omega_{\Lambda,0}a'^4}}} \tag{12.5.167}$$

As far as we know this integral cannot be solved formally. We have to use numerical integration. For example, using the following Maple™ 17 commands:

```
H0:=0.218E-17;OmegaR:=0.924E-4;OmegaM:=0.315;OmegaK:=0;OmegaD:=0.865;
evalf((int(a/(H0*sqrt(a^4*OmegaD+a^2*OmegaK+a*OmegaM+OmegaR)), a =
0.1E-6..1))/(24*(60*60)*365.25));
```

we get:

$$t(a)\cong 13.31932\,[\text{billion years}]$$

Now let's come back to:

$$H(a)\cong H_0\sqrt{\Omega_{r,0}a^{-4}+\Omega_{m,0}a^{-3}+\Omega_{k,0}a^{-2}+\Omega_{X,0}a^{-3(1+\omega)}} \tag{12.5.168}$$

In the minimal Lambda-CDM model (there are other models than the Lambda Cold Dark Matter model like the SIDM - Strong Interactive Dark Matter - model...), it is assumed that curvature Ω_k is zero (flat universe) and $w(T)=-1$ dominated by vacuum, so this simplifies to something knows sometimes under the name "concordance model" and denoted traditionally in most textbooks:

$$H(a)\cong H_0\sqrt{\Omega_m a^{-3}+\Omega_{\text{rad}}a^{-4}+\Omega_\Lambda} \tag{12.5.169}$$

This model is often designated under the name of "late-time model, i.e. after the epoch of matter-radiation equality. The radiation density is then less and less important and the only relevant ingredients are matter and vacuum energy.

Observations show that the radiation density in our observable universe is very small today ($\Omega_{\text{rad}}\sim 10^{-4}$), if this term is neglected the above equation reduces to:

$$H(a)\cong H_0\sqrt{\Omega_m a^{-3}+\Omega_\Lambda} \tag{12.5.170}$$

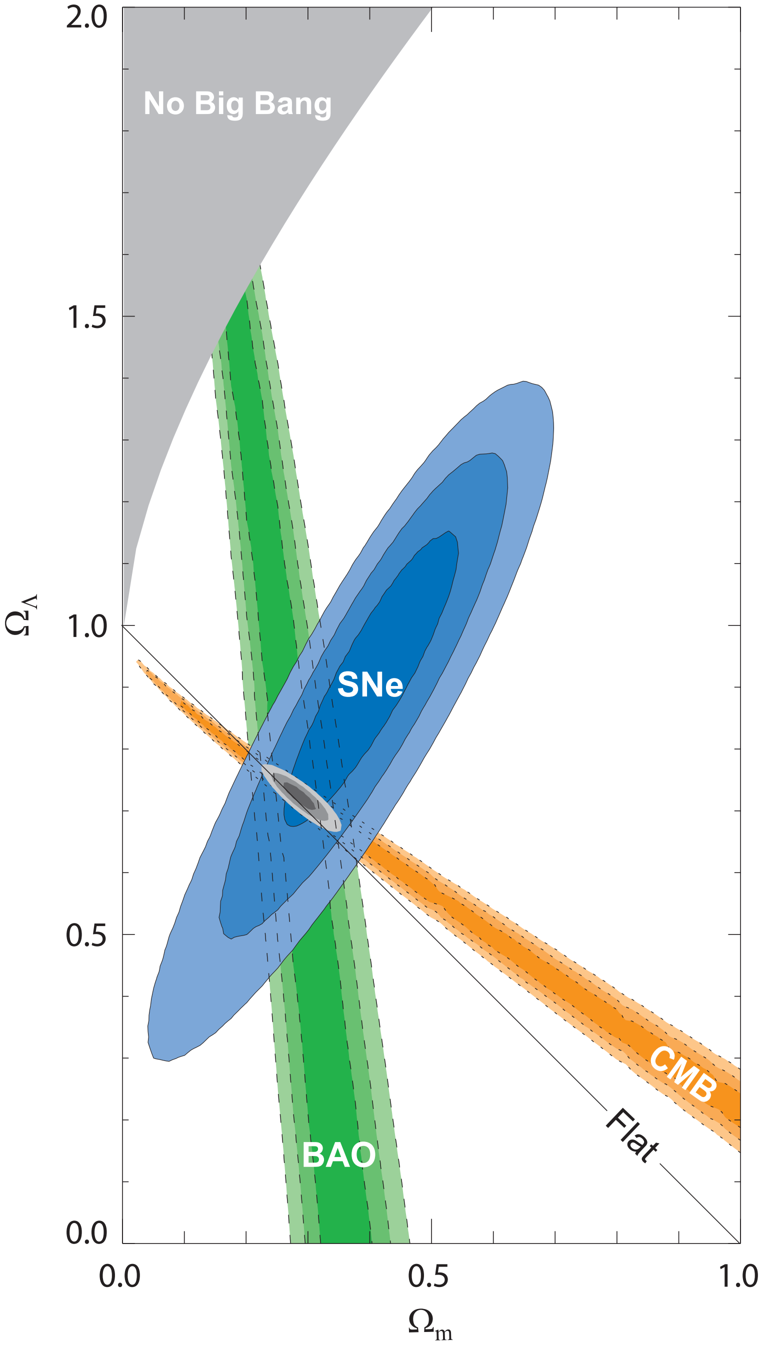
and has an analytic solution that we will see further below at page 6038!

The reader must remember that we have already seen earlier above (see page 5898) that by construction:

$$\Omega_m+\Omega_\Lambda=1 \tag{12.5.171}$$

in flat universe.

For information, observationally allowed regions of Ω_m and Ω_Λ at $68.3, 95.4$ and 99.7% confidence level obtained from the cosmic microwave background (CMB) temperature fluctuations (that we will prove in a future version of this textbook), baryon acoustic oscillations (BAO) in large-scale structure data (that we will also prove in a future version of this textbook), and from the supernova (SN) brightness-distance relation (that we will also prove in a future version of this textbook...). Also shown is the combined allowed region (figure from Kowalski et al. 12008, http://arxiv.org/abs/0804.4142, published in Astrophysical Journal 686 (12008) $749-778$):



From a combination of cosmic microwave background (CMB) and large scale structure (LSS) observations, astrophysicists conclude actually that our observable universe is spatially flat and is composed of 4% mater, 23% dark matter and 73% dark energy (vacuum energy or cosmological constant Λ), i.e.:

$$\Omega_k \cong 0 \qquad \Omega_m = \Omega_M + \Omega_{\text{DM}} \cong 0.04 + 0.23 \qquad \Omega_\Lambda \cong 0.73 \tag{12.5.172}$$

The reader must never forget the margin of error of our Universe age estimation that is at the day we write these lines (year 12023 according to holocene calendar) using other data than Planck of approximately plus/minus one billion year... as illustrated below:

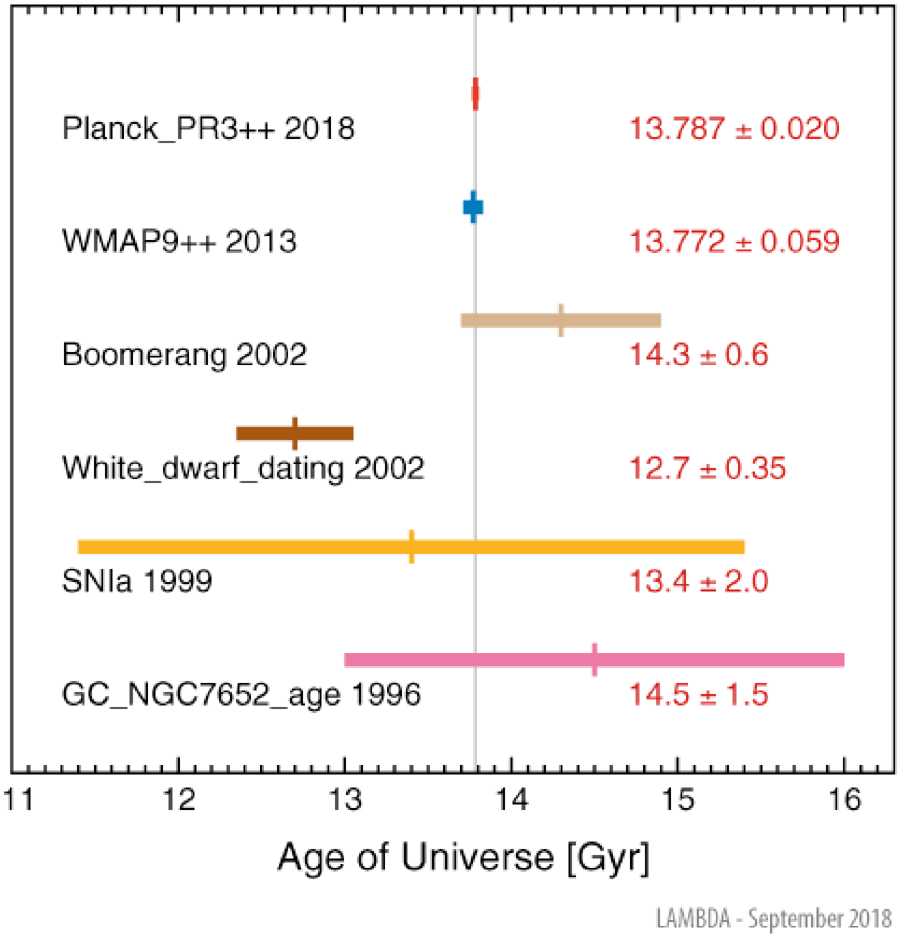


Figure 12.262: **Various estimations of our Universe age as in 12018 (source: NASA / LAMBDA Archive Team)**

12.5.3.1.3 Flat space dominated by vacuum

With everything we have seen so far, we know that for vacuum ($n = 0$):

$$R^n \rho = R_0^n \rho_0 \Rightarrow \rho_V = \rho_{V,0} \tag{12.5.173}$$

But also that:

$$\omega(T) = -1 \tag{12.5.174}$$

Therefore:

$$\rho(t) \propto R(t)^{-3(1+\omega(T))} = R^0(t) = 1 \tag{12.5.175}$$

and:

$$P=\omega\rho=-\rho \tag{12.5.176}$$

Under these conditions, the first Friedmann equation:

$$\left(\frac{R'}{R}\right)^2=\frac{8\pi G\rho}{3}-\frac{k}{R^2} \tag{12.5.177}$$

becomes first by changing into energy density of vacuum and with k being put as equal to zero:

$$\left(\frac{\dot{R}}{R}\right)^2=\frac{8\pi G\rho_V}{3c^2} \tag{12.5.178}$$

and so we can replace the energy density by the result we get just before:

$$\left(\frac{\dot{R}}{R}\right)^2=\frac{8\pi G\rho_{V,0}}{3c^2} \tag{12.5.179}$$

Then we have:

$$\frac{\mathrm{d}R}{\mathrm{d}t}=\sqrt{\frac{8\pi G\rho_{V,0}}{3c^2}}R^2 \tag{12.5.180}$$

hence:

$$R^2\,\mathrm{d}R=\sqrt{\frac{8\pi G\rho_{V,0}}{3c^2}}\,\mathrm{d}t \tag{12.5.181}$$

The primitive is obvious and is immediate:

$$\frac{1}{3}R^3+c^{te}=\sqrt{\frac{8\pi G\rho_{V,0}}{3c^2}}t \tag{12.5.182}$$

At the time $t=0$ of the "Big Bang", many textbooks assume the scale factor is equal to $R=0$ (only in the purpose to simplify the notations!!!) and thus the constant is zero (don't forget that in reality we should rather assume that it as equal to -2 instead to have after rearranging a $+1$ on the right side of the equality when $t=0$). Then we have:

$$\frac{1}{3}R^3=\sqrt{\frac{8\pi G\rho_{V,0}}{3c^2}}t \tag{12.5.183}$$

Thus after simplification it remains:

$$R=\left(\frac{72\pi G\rho_{V,0}}{3c^2}\right)^{1/6}t^{1/3}=\left(\frac{72\pi G}{3c^2}\rho_{V,0}\right)^{1/6}t^{1/3}=\left(\frac{72\pi G}{3c^2}\frac{3H_0^2}{8\pi G}\right)^{1/6}t^{1/3} \tag{12.5.184}$$

Thus after simplification it remains only:

$$R=(9H_0)^{1/6}\,t^{1/3} \tag{12.5.185}$$

Using the common notation in theoretical cosmology we get the famous relation often given without proof:

$$\boxed{a(t) \propto t^{1/3}} \tag{12.5.186}$$

Then a flat universe dominated by vacuum has a scaling factor that is growing slightly slower than a flat universe dominated by matter or radiation.

In comparison with Maple™ 4.00b (blue: flat universe dominated by matter, in red: flat universe dominated by radiation, green: flat universe dominated by radiation):

```
>plot([t^(2/3),t^(1/2),t^(1/3)],t=0..2*Pi,0..3,color=[blue,red,green]);
```

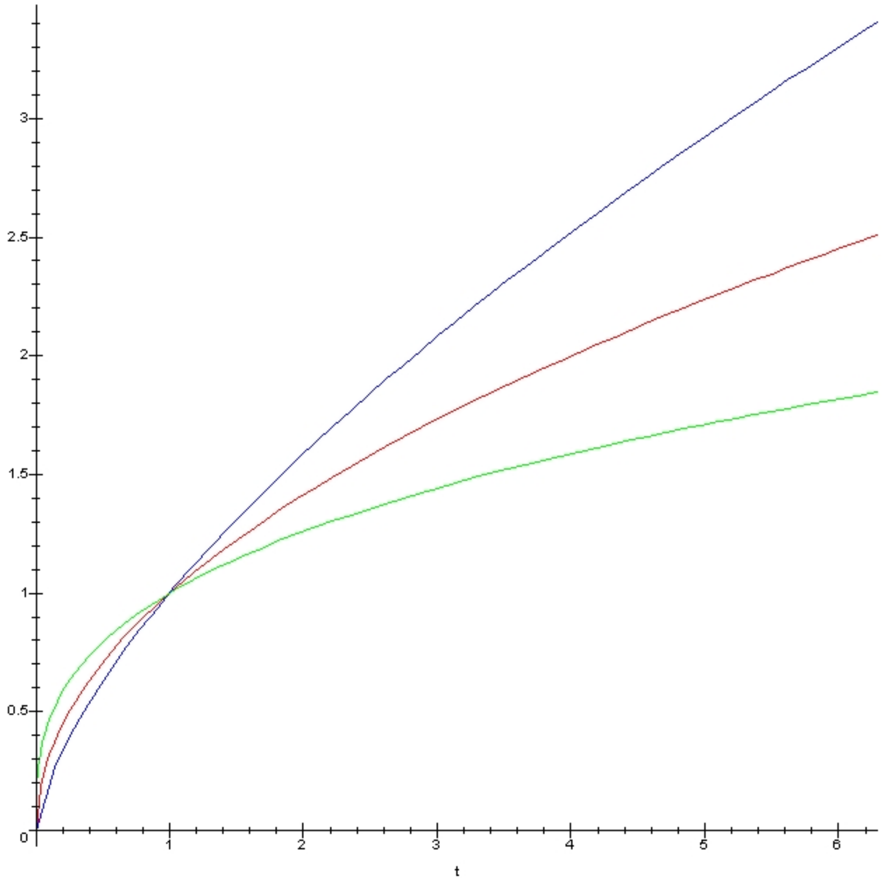

Figure 12.263: **Evolution of R for a zero curvature space dominated by matter, radiation and vacuum**

12.5.3.2 Spherical spaces ($k > 0$)

In this model (also sometimes named "elliptical model"), we consider $k > 0$. So the equation to deal with remains:

$$\mathrm{d}F(t) = \pm\sqrt{\frac{A}{F} - k\mathrm{d}t} \tag{12.5.187}$$

Which can also be written:

$$\Delta t=\pm\int\limits_{t_0}^{t}\frac{1}{\sqrt{\dfrac{A}{F}-k}}\mathrm{d}F(t)\geq 0 \tag{12.5.188}$$

Let us recall that we have assumed that for $t=t_0$ we had $F(t_0)=1$, if we make the change of variable $U=1/F(t)$, we get the following integral:

$$\Delta t=\pm\int\limits_{1}^{1/F}\frac{\mathrm{d}U}{U^2\sqrt{AU-k}} \tag{12.5.189}$$

So we are looking of a primitive of:

$$\Delta t=\int\limits_{1}^{1/F}\frac{\mathrm{d}U}{U^2\sqrt{AU-k}} \tag{12.5.190}$$

and we will discuss the sign ± after having found the primitive.

We still carry a change of variable:

$$x^2=AU-k \tag{12.5.191}$$

thus:

$$2x\mathrm{d}x=A\mathrm{d}U \tag{12.5.192}$$

which gives us the following primitive to calculate:

$$\frac{2}{A}\int\frac{1}{U^2}\mathrm{d}x=\frac{2A^2}{A}\int\frac{1}{x^2+k^2}\mathrm{d}x=\frac{2A}{k^2}\int\frac{1}{\left(\left(\dfrac{1}{\sqrt{k}}\right)^2+1\right)^2}\mathrm{d}s \tag{12.5.193}$$

by doing again a change of variable:

$$y=\frac{x}{\sqrt{k}}\Rightarrow\mathrm{d}x=\sqrt{k}\mathrm{d}y \tag{12.5.194}$$

Therefore to a given multiplicative constant $2Ak^{-3/2}$ we have finally the following integral:

$$\Delta t=\int\frac{\mathrm{d}y}{(1+y^2)^2} \tag{12.5.195}$$

In the section of Differential and Integral Calculus we proved that this form of primitive is resolved by (we add the constant of integration at the end because we do physics and we must satisfy to some initial conditions at which are not necessarily interested to in mathematics):

$$2nI_{n+1}=\frac{y}{(1+y^2)^n}+(2n-1)I_n+c^{te} \tag{12.5.196}$$

with:

$$I_n=\int\frac{\mathrm{d}y}{(1+y^2)^n} \tag{12.5.197}$$

hence:

$$I_2=\frac{1}{2}\frac{y}{(1+y^2)}+\frac{1}{2}I_1 \tag{12.5.198}$$

We still have to calculate I_1 (see section Differential and Integral Calculus page 1534):

$$I_1=\int\frac{1}{(1+y^2)}\mathrm{d}y=\arctan(y)+c^{te} \tag{12.5.199}$$

Finally:

$$I_2=\frac{1}{2}\frac{y}{(1+y^2)}+\frac{1}{2}\arctan(y)+c^{te} \tag{12.5.200}$$

by inverting all the changes of variables and introducing the multiplicative constant again, we have finally in the case where $k>0$:

$$I_2=\frac{\sqrt{AU-k}}{kU}+\frac{A}{k^{3/2}}\arctan\left(\frac{\sqrt{AU-k}}{\sqrt{k}}\right)+\frac{2A}{k^{3/2}}c^{te} \tag{12.5.201}$$

Between the two terminals of integration $(1/F,1)$ we therefore have (the integration constant cancels and we take back the $\pm$ which was originally in the primitive):

$$\Delta t=\pm\left[\left(\frac{F\sqrt{A/F-k}}{k}+\frac{A}{k^{3/2}}\arctan\left(\frac{\sqrt{A/F-k}}{\sqrt{k}}\right)\right)-\left(\frac{\sqrt{A-k}}{k}+\frac{A}{k^{3/2}}\arctan\left(\frac{\sqrt{A-k}}{\sqrt{k}}\right)\right)\right] \tag{12.5.202}$$

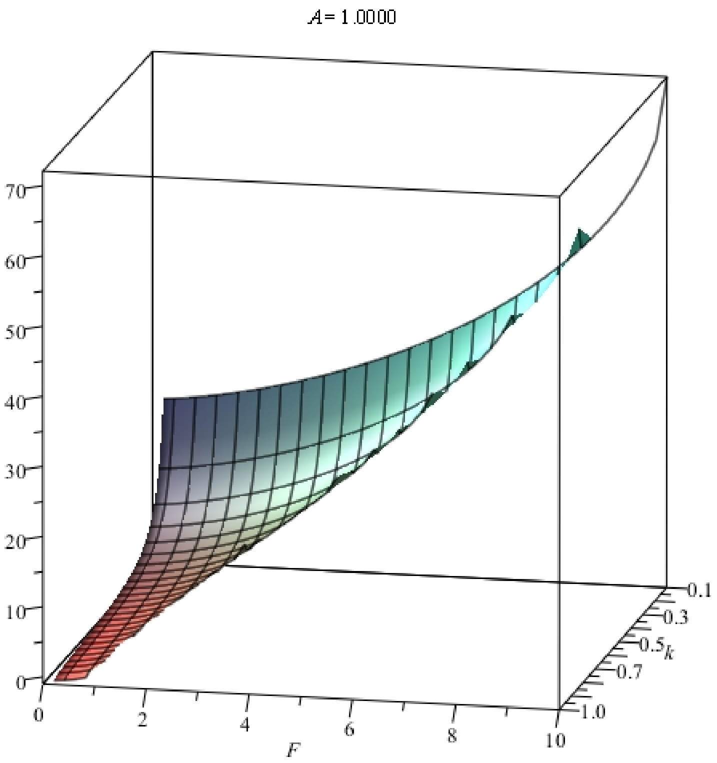
where for recall the theory request that $\Delta t>0$ (otherwise it's pure speculation and philosophy...).

We see that as expected (!!!), if we $F=1$ in the above relation we have indeed $\Delta t=0$ (that means that at the moment in time we take the Universe actual size as reference, the time variation is indeed equal to 0 as expected). In other words, we also have for this model (changing to the other typical notation for the scale factor):

$$\lim_{t\rightarrow 0}a(t)=1 \tag{12.5.203}$$

If we plot this function for a fixed value $k>0$. We have the following animated plot Maple™ in 17.00 for the negative sign:

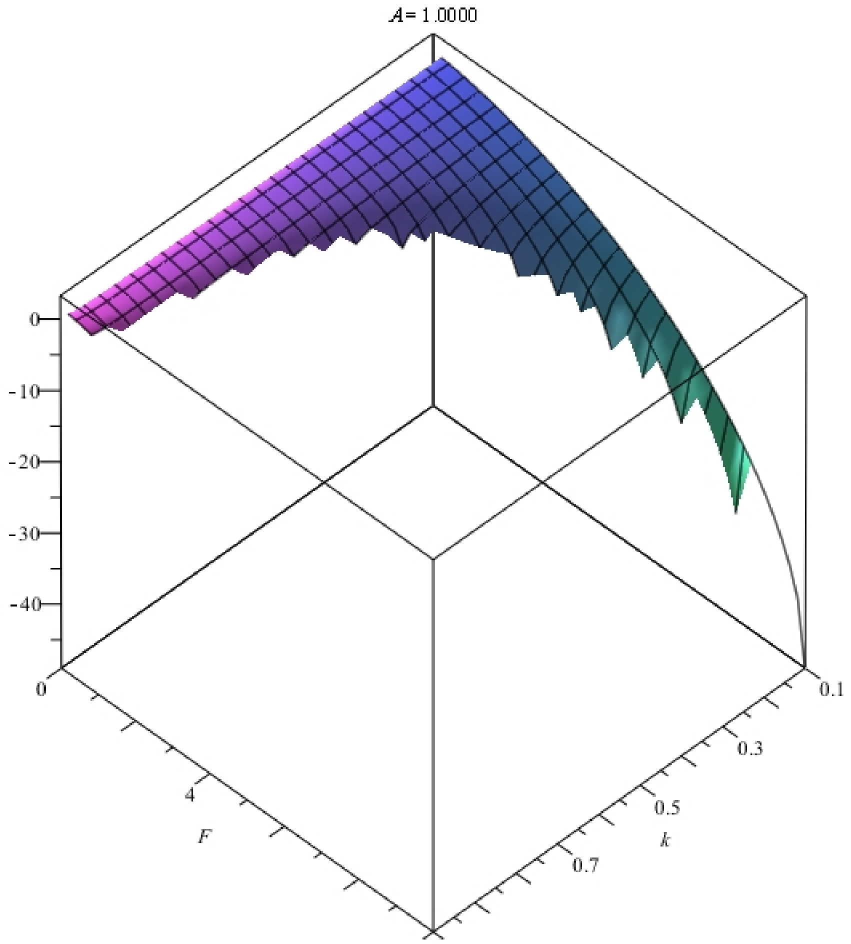
```
>restart:
>f:=(A,k,F)->-[(F*sqrt(A/F-k)/k+A/k^(3/2)*arctan(sqrt(A/f-k)/sqrt(k)))
-(sqrt(A-k)/k+A/k^(3/2)*arctan(sqrt(A-k)/sqrt(k)))]:
>plots:-animate(plot3d,[f(A,k,F),k=0.1..1,F=0..10,],A=0..1)
```



We can see with this solution that as time increase the Universe reach an asymptote size whatever the value of k, but the bigger is k the faster the asymptote is reached. In other words... we must be lucky not to be in a Universe with a to big positive curvature...

And for the positive sign:

```
>restart:
>f:=(A,k,F)->+[(F*sqrt(A/F-k)/k+A/k^(3/2)*arctan(sqrt(A/f-k)/sqrt(k)))
-(sqrt(A-k)/k+A/k^(3/2)*arctan(sqrt(A-k)/sqrt(k)))]:
>plots:-animate(plot3d,[f(A,k,F),k=0.1..1,F=0..10,],A=0..1)
```



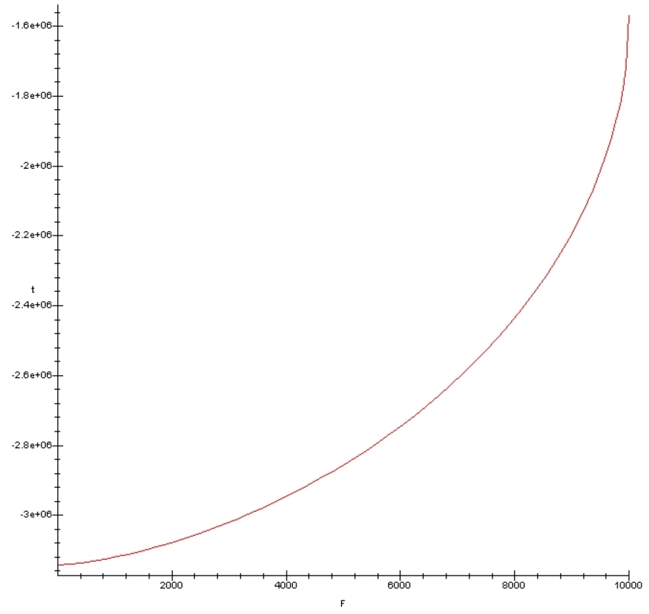
We can see that this solution seems to be the symmetric with the previous plot. That means as time reached back to the zero value, the Universe contracts on single point back and once again this effect is slower as k is big!

Remark

The time Δt in the above plots is always represented on the vertical axis and also for all the following charts further below (you have to turn your head a little if as usually you want to put the time on the horizontal axis...).

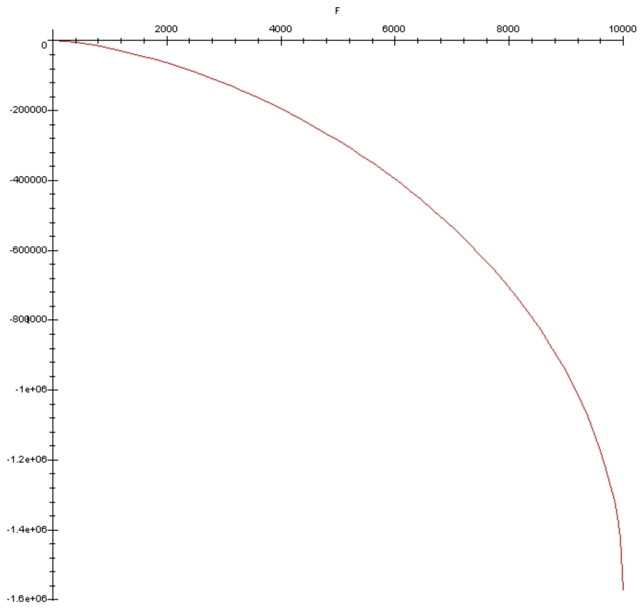
By fixing a small value of A and for k, we get the following two-dimensional plot first for the negative sign:

```
>k:=0.0001;A:=1;
>plot([-(F*sqrt(A/F-k)/k+A/k^(3/2)*arctan(sqrt(A/F-k)/sqrt(k)))-(sqrt(A-k)/k
+A/k^(3/2)*arctan(sqrt(A-k)/sqrt(k)))],F=1..10000,labels=[F,t])
```



where as we have already mentioned it, the reader must keep in mind that the values below 1 must be rejected!

And for the positive sign:



By looking at the both plots above it is obvious to see that we have after a rotation and putting each one next to the other (we also could change the time reference to have a logical time axis):

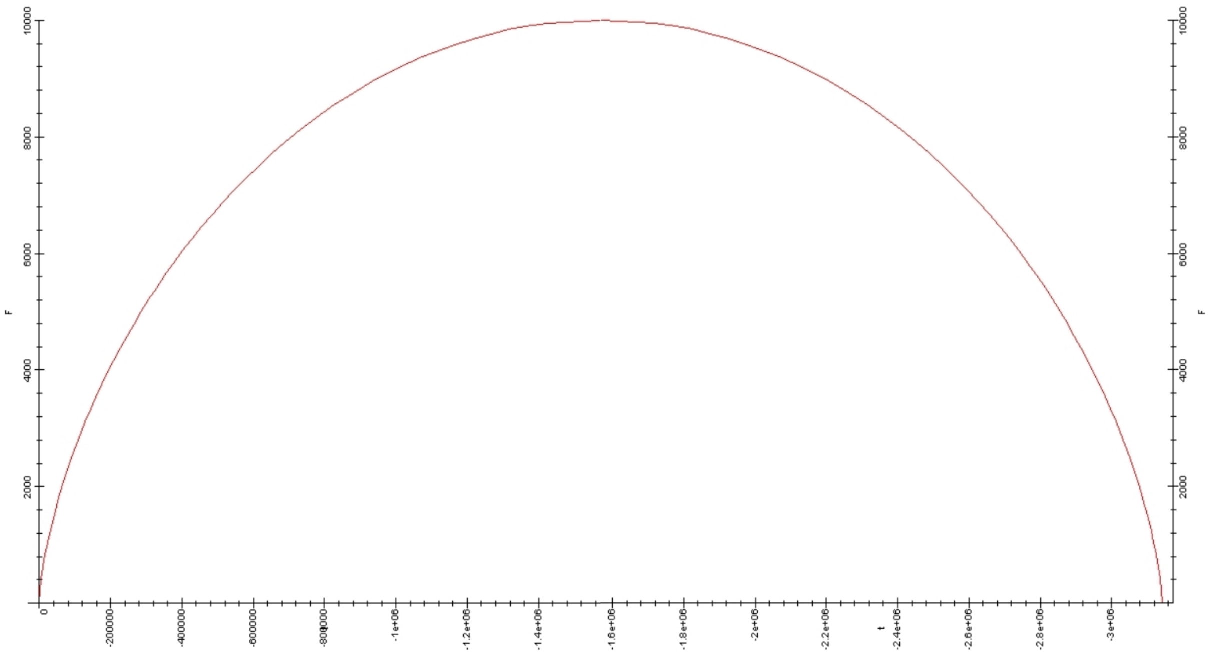


Figure 12.264: **Big Bang and Big Crunch plot side by side**

and what we see here is the Big Bang and the Big Crunch!

Now let us recall that to build the previous model we started from:

$$(\mathrm{d}_t F)^2 = \frac{8\pi}{3} G\rho_0 F^{-1} - k \tag{12.5.204}$$

A limit condition (condition of integration) is that the right term to be positive. That is:

$$F_{\text{lim}} = \frac{8\pi G\rho_0}{3k} \tag{12.5.205}$$

or:

$$F_{\text{lim}}^{-1} = \frac{3k}{8\pi G\rho_0} = \frac{k}{A} \tag{12.5.206}$$

So for our previous 2D plot this limit is located at $F = k/A = 10,000$ and this is according to the maximum value before the Universe turn into a Big Crunch!

So if F^{-1} is smaller than F_{lim}^{-1}, we are not in a valid (real) domain model anymore.

In fact, beyond the time limit t_{lim} corresponding to this F_{lim}, what does not know the computer that has drawn our function plot is that it should switch to the scaling function with the "$+$". So when we execute the plot of both functions we should get the previous figure.

We see then that for $t < t_{\text{lim}}$ the Universe is entering a phase of contraction that we commonly name the "Big Crunch". After this phase of contraction, it is possible that either the Universe disappears completely in a singularity or that it re-enters a cyclical dynamic phase (mathematically the two outcomes seem to be possible).

12.5.3.2.1 Spherical space dominated by matter

Just as the model for flat space, there is also another approach much more elegant and subtle for my taste than the previous proof (I have also discovered that many years after writing the previous text). It also has the advantage of highlighting a hypothesis that has not appear with previous developments and allows to plot more simply in Maple™ 4.00b the behaviour of the scale factor of the Universe. We thus find exactly the famous plot representing the evolution of the scale factor of the Universe available in almost all popular books on the subject (without proofs obviously...).

We start again from the first Friedmann equation:

$$\left(\frac{R'}{R}\right)^2=\frac{8\pi G\rho}{3}-\frac{k}{R^2} \tag{12.5.207}$$

It is customary for this model equation to put $k=+1$ (even take any positive number at least pick one that is friendly...) and we have shown that when matter dominates, we had:

$$R^3\rho=R_0^3\rho_0=c^{te} \tag{12.5.208}$$

Since then:

$$\frac{R'^2}{R^2}=\frac{8\pi G}{3}\rho_0\left(\frac{R_0}{R}\right)^3-\frac{1}{R^2} \tag{12.5.209}$$

and it comes immediately:

$$\frac{\mathrm{d}R}{\mathrm{d}t}=\sqrt{\frac{8\pi G\rho_0R_0^3}{3R}-1} \tag{12.5.210}$$

Therefore:

$$\int\mathrm{d}t=\int\frac{1}{\sqrt{\dfrac{8\pi G\rho_0R_0^3}{3R}-1}}\mathrm{d}R \tag{12.5.211}$$

If we move now to the comoving time also named "conformal time" (already introduced at the beginning of this section) defined mathematically by (don't forget that R is not a radius but a ratio of two radius!):

$$\mathrm{d}\eta=\frac{\mathrm{d}t}{R} \tag{12.5.212}$$

Then we have:

$$\int\mathrm{d}\eta=\int\frac{1}{\sqrt{\dfrac{8\pi G\rho_0R_0^3}{3}R-R^2}}\mathrm{d}R \tag{12.5.213}$$

Let us write that in the form:

$$\int\mathrm{d}\eta=\int\frac{1}{\sqrt{AR-R^2}}\mathrm{d}R \tag{12.5.214}$$

where A is strictly positive. Let us do the substitution:

$$R=x+\frac{A}{2} \tag{12.5.215}$$

Then we have:

$$\begin{gathered}\int \mathrm{d}\eta=\int\frac{1}{\sqrt{A\left(x+\dfrac{A}{2}\right)-\left(x+\dfrac{A}{2}\right)^2}}\mathrm{d}x=\int\frac{1}{Ax+\dfrac{A^2}{x}-\left(x^2+Ax+\dfrac{A^2}{4}\right)}\mathrm{d}x\\ =\int\frac{1}{\sqrt{\dfrac{A^2}{4}-x^2}}\mathrm{d}x\end{gathered} \tag{12.5.216}$$

and we have proved in the section of Differential and Integral Calculus (see 1534) that the primitive is:

$$\int\frac{1}{\sqrt{\dfrac{A^2}{4}-x^2}}\mathrm{d}x=\arcsin\left(\frac{2x}{4}\right)+c^{te} \tag{12.5.217}$$

Therefore:

$$\eta=\arcsin\left(\frac{2R-A}{A}\right)+c^{te} \tag{12.5.218}$$

As at time $\eta=0$ we have $R=0$, it is necessary that the constant is such that:

$$\eta=\arcsin\left(\frac{2R-A}{A}\right)+\frac{\pi}{2} \tag{12.5.219}$$

Therefore:

$$\frac{2R-A}{A}=\sin\left(\eta-\frac{\pi}{2}\right)=-\cos(\eta) \tag{12.5.220}$$

Hence:

$$R=\frac{A}{2}(1-\cos(\eta)) \tag{12.5.221}$$

Now, let us recall that:

$$\mathrm{d}\eta=\frac{\mathrm{d}t}{R}\Leftrightarrow \mathrm{d}t=R\mathrm{d}\eta \tag{12.5.222}$$

Therefore:

$$\int \mathrm{d}t=\int R\mathrm{d}\eta=\int\frac{A}{2}(1-\cos(\eta))\mathrm{d}\eta \tag{12.5.223}$$

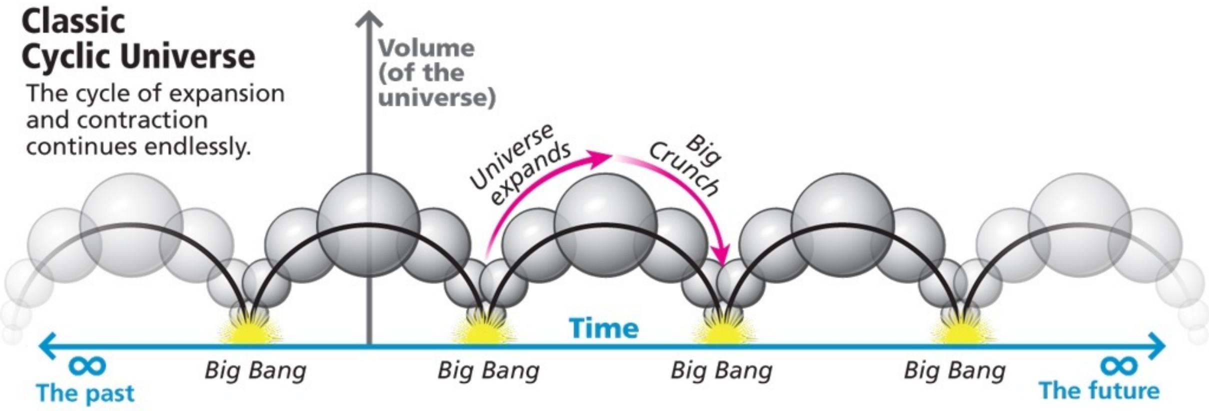
Hence:

$$t=\frac{A}{2}(\eta-\sin(\eta))+c^{te} \tag{12.5.224}$$

and as we must have at time $t=0$ the comoving time that is also zero, the constant is then zero. Therefore we have the following parametric system in the end (something very strange with this result... it is that we fall back on the parametric equations of the brachistochrone curve[62]!!!!):

$$\begin{aligned}R&=\frac{A}{2}(1-\cos(\eta))\\t&=\frac{A}{2}(\eta-\sin(\eta))\end{aligned} \tag{12.5.225}$$

Hence it is periodic and if we can assimilate the result to a Universe that means we have a "Big Bang" and after a given time a "Big Crunch" and the process repeats indefinitely as a "Big Bounce". The idea is more or less (...) the following:



Classic
Cyclic Universe
The cycle of expansion and contraction continues endlessly.
Volume (of the universe)
Universe expands
Big Crunch
Time
∞
The past
Big Bang
Big Bang
Big Bang
Big Bang
∞
The future

Figure 12.265: **Big Bounce artistic illustration (source: ?)**

Remark

Notice that for $\eta=0$, we have $t=0$ but $R\neq 1$ and this wrong value results simply because earlier before we have assumed that for $\eta=0$, R was also equal to zero (but this was obviously an abusive simplification)!

With Maple™ 4.00b we then have by comparing the flat Universe dominated by matter (blue), the flat Universe dominated by radiation (red) and finally the positive curvature Universe dominated by matter (green) and putting artificial coefficients to better distinguish the plots:

```
>plot([t^(2/3),t^(1/2),[0.5*(t-sin(t)),0.5*(1-cos(t)),t=0..2*Pi]],
t=0...Pi,0..2.5,color=[blue,red,green]);
```

---

[62] See section Classical Mechanics page 3433

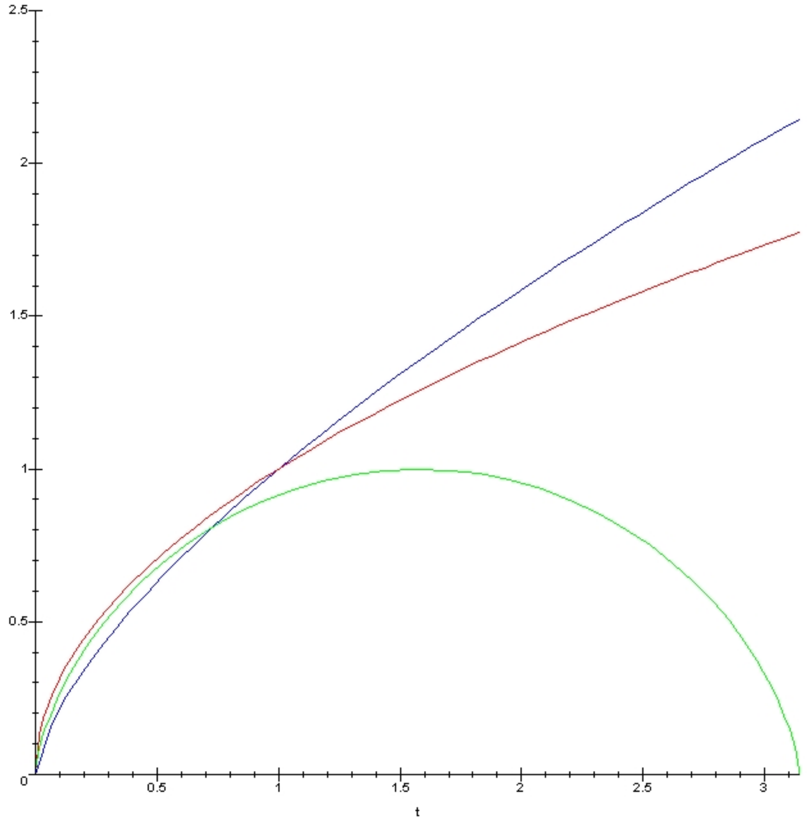


Figure 12.266: Evolution of the R factor for the resulting space configurations studied so far with Maple™ 4.00b

12.5.3.2.2 Spherical space dominated by radiation

Let us now consider a universe dominated by radiation. We have proved earlier above that in this situation we had:

$$P=\frac{1}{3}\rho_E \tag{12.5.226}$$

and:

$$R^4\rho_E=R_0^4\rho_{E,0}=c^{te} \tag{12.5.227}$$

In this case the Friedmann equation in terms of energy density can be written by putting $k=+1$:

$$\left(\frac{R'}{R}\right)^2=\frac{8\pi G\rho_E}{3c^2}-\frac{1}{R^2} \tag{12.5.228}$$

What becomes:

$$\frac{\mathrm{d}R}{\mathrm{d}t}=\sqrt{\frac{8\pi G\rho_E}{3c^2}R^2-1} \tag{12.5.229}$$

By injecting $R^4\rho_E=R_0^4\rho_{E,0}$, it comes:

$$\frac{\mathrm{d}R}{\mathrm{d}t}=\sqrt{\frac{8\pi G\rho_{E,0}R_0^4}{3c^2R^2}-1} \tag{12.5.230}$$

Therefore: Therefore:

$$\int \mathrm{d}t=\int \frac{1}{\sqrt{\dfrac{8\pi G\rho_{E,0}R_0^4}{3c^2R^2}-1}}\mathrm{d}R \tag{12.5.231}$$

Let us write this in the form:

$$\int \mathrm{d}t=\int \frac{1}{\sqrt{\dfrac{A}{R^2}-1}}\mathrm{d}R \tag{12.5.232}$$

If we change to the comoving time again:

$$\eta=\frac{\mathrm{d}t}{R} \tag{12.5.233}$$

Then we have:

$$\int \mathrm{d}\eta=\int \frac{1}{\sqrt{A-R^2}}\mathrm{d}R \tag{12.5.234}$$

In the section of Differential and Integral Calculus (see page 1534) we have proved how to determine exactly the same primitive (because it is a usual primitive). We have:

$$\eta=\arcsin\left(\frac{R}{\sqrt{A}}\right)+c^{te} \tag{12.5.235}$$

For at time $\eta=0$ we have $R=0$, it is necessary that the constant is such that:

$$\eta=\arcsin\left(\frac{R}{\sqrt{A}}\right) \tag{12.5.236}$$

Hence:

$$R=\sqrt{A}\sin(\eta) \tag{12.5.237}$$

Now, remember that:

$$\eta=\frac{\mathrm{d}t}{R}\Leftrightarrow \mathrm{d}t=R\mathrm{d}\eta \tag{12.5.238}$$

Therefore:

$$\int \mathrm{d}t=\int R\mathrm{d}\eta=\int \sqrt{A}\sin(\eta)\mathrm{d}\eta \tag{12.5.239}$$

Hence:

$$t=-\sqrt{A}\cos(\eta)+c^{te} \tag{12.5.240}$$

and as at time $t=0$ the comoving time η is also zero, the constant is therefore equal to $\sqrt{A}$. Therefore we have finally the following parametric system:

$$\begin{aligned}R&=\sqrt{A}\sin(\eta)\\ t&=\sqrt{A}(1-\cos(\eta))\end{aligned} \tag{12.5.241}$$

Remark

Notice that for $\eta=0$, we have $t=0$ but $R\neq 1$ and this wrong value results simply because earlier before we have assumed that for $\eta=0$, R was also equal to zero (but this was obviously an abusive simplification)!

With Maple™ 4.00b we can then compare the flat Universe dominated by matter (blue), the flat Universe dominated by radiation (red), the Universe with positive curvature dominated by matter (green), the Universe with positive curvature dominated by radiation (black):

```
>plot([t^(2/3),t^(1/2),[0.5*(t-sin(t)),0.5*(1-cos(t)),t=0..2*Pi],[0.5*
(1-cos(t)),0.5*sin(t),t=0..2*Pi]],t=0...Pi,0..3,color=[blue,red,green,black]);
```

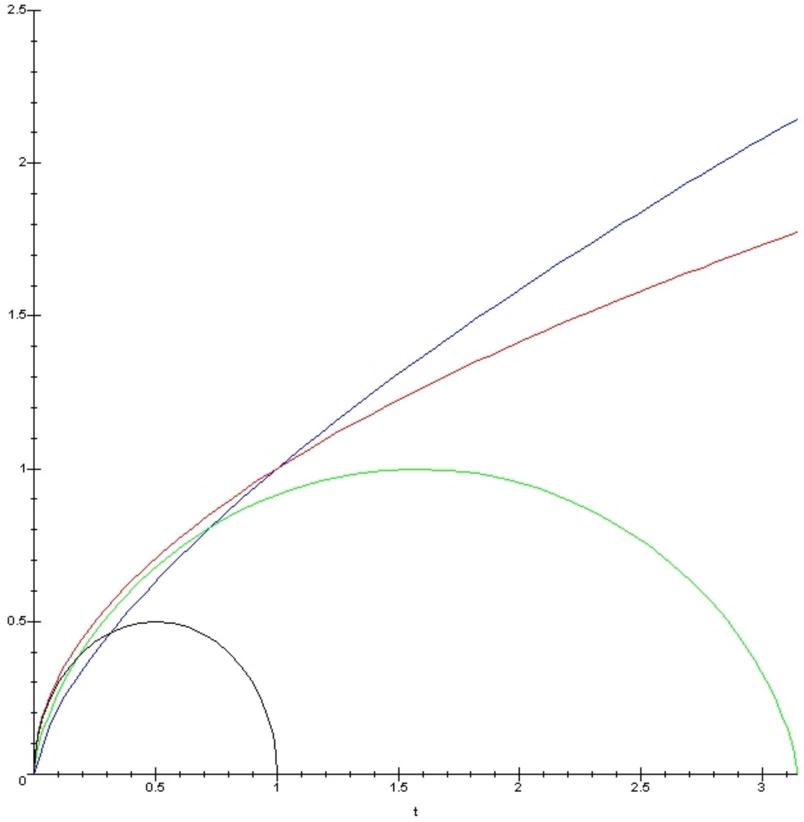

Figure 12.267: **Evolution of the R factor for the resulting space configurations studied so far with Maple™ 4.00b**

12.5.3.2.3 Spherical space dominated by vacuum

Remember that we have seen earlier above that:

$$\rho(t)\propto R(t)^{-3(1+\omega(T))}\propto\begin{cases}R(t)^{-3} & \text{for } \omega(T)=0 \text{ (pressureless matter (i.e. dust))}\\ R(t)^{-4} & \text{for } \omega(T)=1/3 \text{ (radiation/ultra-relativistic matter)}\\ c^{te} & \text{for } \omega(T)=-1 \text{ (vacuum energy)}\end{cases} \tag{12.5.242}$$

And we also have:

$$R^n\rho=R_0^n\rho_0\Rightarrow\begin{cases}n=0\text{ for vacuum}\\ n=3\text{ for matter dominated Universe}\\ n=4\text{ for radiation dominated Universe}\end{cases}\tag{12.5.243}$$

Hence the case that we want to focus here on is when $\omega(T)=-1$.

We start again from the first Friedmann equation:

$$\left(\frac{R'}{R}\right)^2=\frac{8\pi G\rho}{3}-\frac{k}{R^2}\tag{12.5.244}$$

where again we put here $k=+1$ and we have shown that when vacuum dominates, we had:

$$R^0\rho=R_0^0\rho_0=\rho_{V,0}\tag{12.5.245}$$

Since then:

$$\frac{R'^2}{R^2}=\frac{8\pi G\rho_{V,0}}{3}-\frac{1}{R^2}\tag{12.5.246}$$

and it comes immediately:

$$\frac{\mathrm{d}R}{\mathrm{d}t}=\sqrt{\frac{8\pi G\rho_{V,0}R^2}{3}-1}\tag{12.5.247}$$

Therefore:

$$\int\mathrm{d}t=\int\frac{1}{\sqrt{\dfrac{8\pi G\rho_{V,0}R^2}{3}-1}}\mathrm{d}R\tag{12.5.248}$$

We know have already derived the primitive above during our study of usual primitives in the section of Integral and Differential Calculus at page 1534.

Therefore we get:

$$t=\sqrt{\frac{3}{8\pi G\rho_{V,0}}}\ln\left(\sqrt{\frac{8\pi G\rho_{V,0}}{3}}R+\sqrt{\frac{8\pi G\rho_{V,0}}{3}R^2-1}\right)\tag{12.5.249}$$

Taking the exponential of the above relation, squaring and solving the second degree polynomial relatively to R gives:

$$R=\frac{1}{2}\frac{1+e^{t^2\left(\frac{8\pi G\rho_{V,0}}{3}\right)^2}}{\sqrt{\frac{8\pi G\rho_{V,0}}{3}}e^{t\sqrt{\frac{8\pi G\rho_{V,0}}{3}}}}\tag{12.5.250}$$

The latter has a real solution for all $t\in\mathbb{R}$. With Maple™ 4.00b only for $t>0$ (it's symmetrical in negative axis if we choose the right integration constant), we get roughly something like the following:

```
>plot(1+exp(t^2))/exp(t),t=0..3);
```

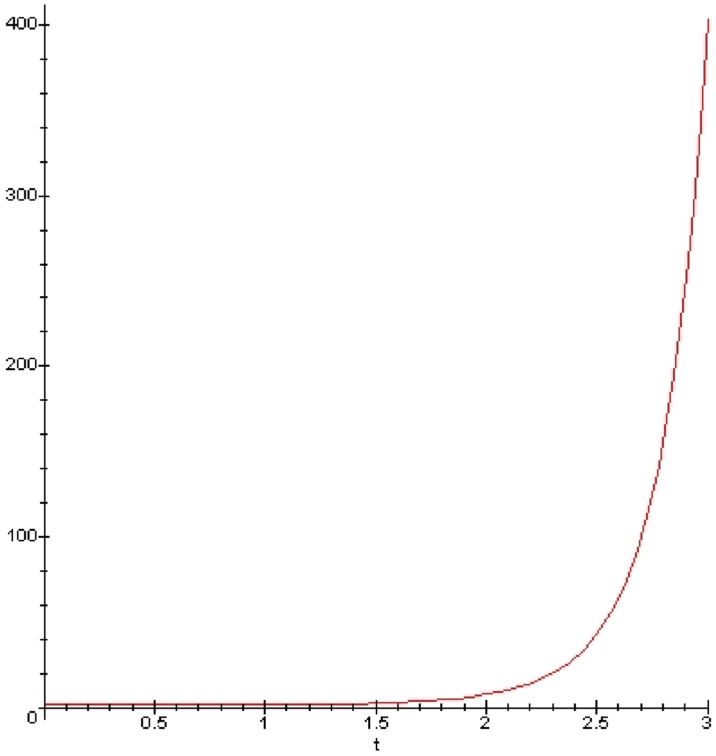

Figure 12.268: Evolution of R for a spherical space dominated by vacuum

12.5.3.3 Hyperbolic spaces ($k<0$)

In this model, we consider $k<0$. So the equation to be treated can be written:

$$\mathrm{d}F(t)=\pm\sqrt{\frac{A}{F}+|k|}\mathrm{d}t \tag{12.5.251}$$

Which is also written:

$$\Delta t=\pm\int\limits_{t_0}^{t}\frac{1}{\sqrt{\dfrac{A}{F}+|k|}}\mathrm{d}t \tag{12.5.252}$$

Let us recall that we assumed that $t=t_0$ that $F(t_0)=1$. If we make the change of variable $U=1/F(t)$, we get the following integral:

$$\Delta t=\pm\int\limits_{1}^{1/F}\frac{\mathrm{d}U}{U^2\sqrt{AU+|k|}}\geq 0 \tag{12.5.253}$$

So we are looking for a primitive of:

$$\Delta t=\int\frac{\mathrm{d}U}{U^2\sqrt{AU+|k|}}\geq 0 \tag{12.5.254}$$

and we will discuss the sign ± after finding the primitive.

We still carry a change of variable by putting:

$$x^2 = AU + k \tag{12.5.255}$$

therefore:

$$2x\mathrm{d}x = A\mathrm{d}U \tag{12.5.256}$$

which gives us the following primitive to calculate:

$$\frac{2}{A}\int\frac{1}{U^2}\mathrm{d}x = \frac{2A^2}{A}\int\frac{1}{(x^2-k)^2}\mathrm{d}x = \frac{2A}{k^2}\int\frac{1}{\left(\left(\frac{x}{\sqrt{x}}-1\right)^2\right)^2}\mathrm{d}x \tag{12.5.257}$$

Doing again a change of variable:

$$y = \frac{x}{\sqrt{x}} \Rightarrow \mathrm{d}x = \sqrt{k}\mathrm{d}y \tag{12.5.258}$$

hence to a given multiplicative constant:

$$\frac{2A}{k^{3/2}} \tag{12.5.259}$$

We have:

$$\int\frac{\mathrm{d}y}{(y^2-1)^2} = \int\frac{\mathrm{d}y}{(1-y^2)^2} \tag{12.5.260}$$

In the section of Differential and Integral Calculus (see page 1534) we saw that this form of primitive is resolved by the relation (we added the constant of integration in the end because we do physics and must satisfy the initial conditions to which we were not interested to in pure mathematics):

$$2nI_{n+1} = \frac{y}{(1-y^2)^n} + (2n-1)I_n + c^{te} \tag{12.5.261}$$

with:

$$I_n = \int\frac{\mathrm{d}y}{(1-y^2)^n} \tag{12.5.262}$$

hence:

$$I_2 = \frac{1}{2}\frac{y}{1-y^2} + \frac{1}{2}I_1 \tag{12.5.263}$$

We still need to calculate I_1:

$$\begin{aligned}I_1 &= \int\frac{1}{1-y^2}\mathrm{d}y = \frac{1}{2}\int\left(\frac{1}{1+y}+\frac{1}{1-y}\right)\mathrm{d}y = \frac{1}{2}\ln(|1+y|) - \ln(|1-y|)\\ &= \frac{1}{2}\ln\left(\left|\frac{1+y}{1-y}\right|\right) + c^{te}\end{aligned} \tag{12.5.264}$$

Finally:

$$I_2=\frac{1}{2}\frac{y}{1-y^2}+\frac{1}{4}\ln\left(\left|\frac{1+y}{1-y}\right|\right)+c^{te} \qquad (12.5.265)$$

by putting back all the changes of variables and introducing the multiplicative constant again, we have therefore in the case $k>0$:

$$I_2=-\frac{\sqrt{AU+|k|}}{kU}+\frac{A}{2|k|^{3/2}}\ln\left(\left|\frac{\sqrt{|k|}+\sqrt{AU+|k|}}{\sqrt{|k|}-\sqrt{AU+|k|}}\right|\right)+\frac{2A}{|k|^{3/2}}c^{te} \qquad (12.5.266)$$

Between the two terminals of integration $(1/F,1)$ so we have (the integration constant is zero):

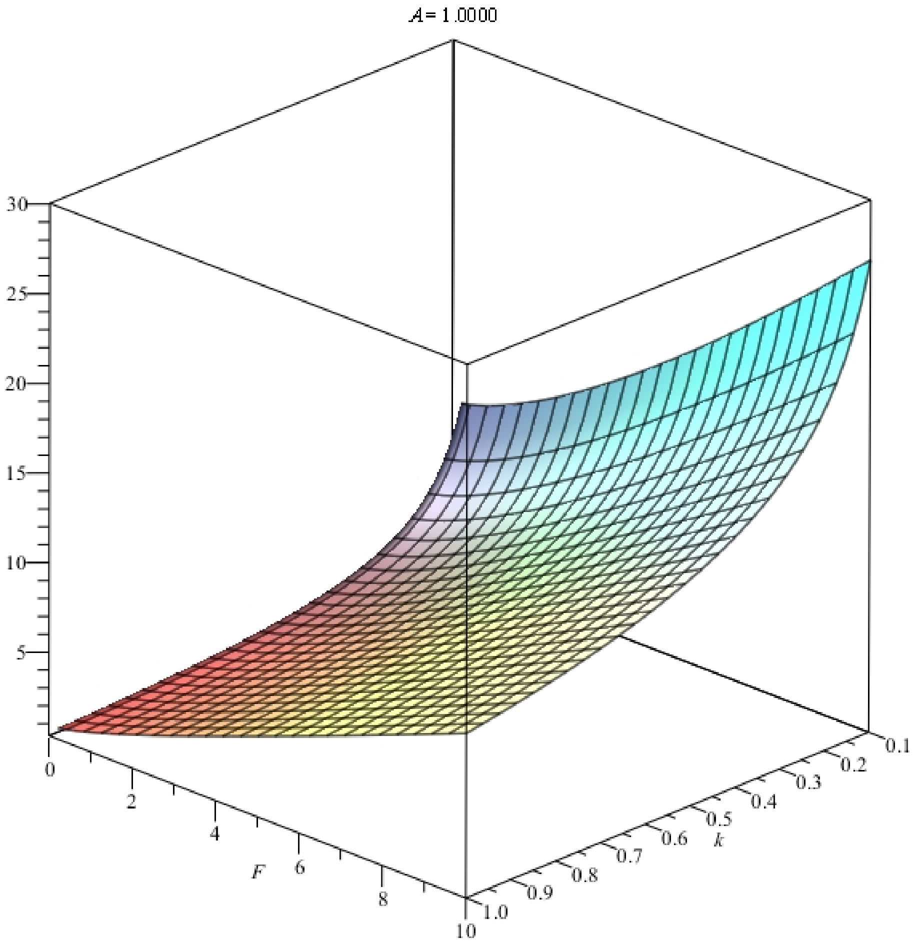
$$\begin{aligned}\Delta t=&\left(-\frac{-F\sqrt{A/F+|k|}}{k}+\frac{A}{2|k|^{3/2}}\ln\left(\left|\frac{\sqrt{k}+\sqrt{A/F+|k|}}{\sqrt{|k|}-\sqrt{A/F+|k|}}\right|\right)\right)\\&-\left(\frac{-\sqrt{A+|k|}}{k}+\frac{A}{2|k|^{3/2}}\ln\left(\left|\frac{\sqrt{|k|}+\sqrt{A/F+|k|}}{\sqrt{|k|}-\sqrt{A/F+|k|}}\right|\right)\right)\end{aligned} \qquad (12.5.267)$$

We must obviously have (we take back the ± which was originally in the integral):

$$\Delta t=\pm\left(\frac{-F\sqrt{A/F+|k|}+\sqrt{A+|k|}}{k}+\frac{A}{2|k|^{3/2}}\ln\left(\frac{\ln\left(\left|\frac{\sqrt{k}+\sqrt{A/F+|k|}}{\sqrt{|k|}-\sqrt{A/F+|k|}}\right|\right)}{\ln\left(\left|\frac{\sqrt{|k|}+\sqrt{A/F+|k|}}{\sqrt{|k|}-\sqrt{A/F+|k|}}\right|\right)}\right)\right) \qquad (12.5.268)$$

If we plot this function for a fixed value $k>0$ we then have the following animated plot with Maple™ 17.00 for the negative sign (as the positive one has no physical meaning):

```
>restart:
>f:=(A,k,F)->-(((-F(sqrt(A/F+abs(k)))/k+A/2(2*abs(k)^(3/2))*ln(abs(((sqrt(
abs(k))+sqrt(A/F+abs(k)))/(sqrt(abs(k))-sqrt(A/F+abs(k))))/((sqrt(abs(k))
+sqrt(A+abs(k)))/(sqrt(abs(k))-sqrt(A+abs(k)))))))):
>plots:-animate(plot3d,[f(A,k,F),k=0.1..1,F=0..10,],A=0.1..1)
```



We see that the smaller is the constant A, the fastest the Universe increases indefinitely quickly! Furthermore for a fixed value of k, some values of A are prohibited (it is in fact still the integration condition).

Again we see that the in the equation above the criterion $F(t_0)=F(0)=1$ is naturally fully respected. All values $F(t)$ below 1 are to be rejected! Hence using again the one of the traditional notation:

$$\lim_{t\to 0} a(t)=1 \tag{12.5.269}$$

So we have in this hyperbolic model a Universe that grows indefinitely in an exponential away (as the flat Friedmann-Lemaître model) because since $k<0$, there is no integration condition limit anymore (unlike the previous spherical model).

12.5.3.3.1 Hyperbolic space dominated by matter

Just as for the models for flat and spherical space, there is also another approach much more elegant and subtle for my taste than the previous proof (I have also discovered that one many years after writing the previous version). It also has the advantage of highlighting a hypothesis that has not occurred with previous developments and allows to draw more simply in Maple™ 4.00b the behaviour of the scale factor of the Universe. We thus find exactly the famous plot representing the evolution of the scale factor of the Universe available in almost all popular books on the subject but without proof.

We always start from the first Friedmann equation:

$$\left(\frac{R'}{R}\right)^2=\frac{8\pi G\rho}{3}-\frac{k}{R^2} \tag{12.5.270}$$

It is customary for this model to put $k=-1$ (as we have to choose any negative number at least we pick one that is friendly...) and we have proved that when the radiation dominates, we had:

$$R^3\rho=R_0^3\rho_0=c^{te} \tag{12.5.271}$$

In this case the Friedmann equation in terms of energy density can be written by putting $k=-1$:

$$\left(\frac{R'}{R}\right)^2=\frac{8\pi G\rho_E}{3c^2}-\frac{1}{R^2} \tag{12.5.272}$$

The first Friedmann equation then becomes:

$$\left(\frac{R'}{R}\right)=\frac{8\pi G\rho}{3}+\frac{1}{R^2}=\frac{8\pi G\rho_0}{3}\left(\frac{R_0}{R}\right)^3+\frac{1}{R^2} \tag{12.5.273}$$

Then we have:

$$\frac{\mathrm{d}R}{\mathrm{d}t}=\sqrt{\frac{8\pi G\rho_0 R_0^3}{3R}+1} \tag{12.5.274}$$

Hence:

$$\int \mathrm{d}t=\int\frac{1}{\sqrt{\frac{8\pi G\rho_0 R_0^3}{3R}+1}}\mathrm{d}R \tag{12.5.275}$$

This is exactly the same integral than that of the spherical Universe dominated by matter at the difference that in the root, we $+1$ instead of -1. We will proceed in the same manner using the time comoving time:

$$\mathrm{d}\eta=\frac{\mathrm{d}t}{R} \tag{12.5.276}$$

It comes then:

$$\int \mathrm{d}\eta=\int\frac{1}{\sqrt{\frac{8\pi G\rho_0 R_0^3}{3}+R^2}}\mathrm{d}R \tag{12.5.277}$$

Let us write that in the form:

$$\int \mathrm{d}\eta = \int \frac{1}{AR+R^2}\mathrm{d}R \tag{12.5.278}$$

where A is strictly positive. Let us make the substitution:

$$R = x - \frac{A}{2} \tag{12.5.279}$$

Then we have:

$$\begin{aligned}\int \mathrm{d}\eta &= \int \frac{1}{\sqrt{A\left(x-\dfrac{A}{2}\right)+\left(x-\dfrac{A}{2}\right)^2}}\mathrm{d}x = \int \frac{1}{\sqrt{Ax-\dfrac{A^2}{2}+\left(x^2-Ax+\dfrac{A^2}{4}\right)^2}}\mathrm{d}x\\ &= \int \frac{1}{\sqrt{x^2-\dfrac{A^2}{4}}}\mathrm{d}x\end{aligned} \tag{12.5.280}$$

Using the usual primitive proved in the section of Differential and Integral Calculus (see page 1534) it comes:

$$\int \frac{1}{\sqrt{x^2-\dfrac{A^2}{4}}}\mathrm{d}x = \text{arccosh}\left(\frac{2x}{A}\right)+c^{te} \tag{12.5.281}$$

Or redoing the change of variables:

$$\text{arccosh}\left(\frac{4x}{A^2}\right)+c^{te} = \text{arccosh}\left(\frac{2\left(R+\dfrac{A}{2}\right)}{A}\right)+c^{te} = \text{arccosh}\left(\frac{2R+A}{A}\right)+c^{te} \tag{12.5.282}$$

Therefore:

$$\eta = \text{arccosh}\left(\frac{2R+A}{A}\right)+c^{te} \tag{12.5.283}$$

So that at time $\eta=0$ we have $R=0$, it is necessary that the constant is such that:

$$\frac{\cosh(-c^{te})A-A}{2}=0 \tag{12.5.284}$$

Which brings us to that the constant is zero and thus:

$$\eta = \text{arccosh}\left(\frac{2R+A}{A}\right) \tag{12.5.285}$$

Therefore:

$$\frac{2R+A}{A} = \cosh(\eta) \tag{12.5.286}$$

Hence:

$$R=\frac{A}{2}(\cosh(\eta)-1) \tag{12.5.287}$$

and as:

$$\mathrm{d}\eta=\frac{\mathrm{d}t}{R} \tag{12.5.288}$$

We have:

$$\int \mathrm{d}t=\int R\mathrm{d}\eta=\int \frac{A}{2}(\cosh(\eta)-1)\mathrm{d}\eta \tag{12.5.289}$$

Which gives:

$$t=\frac{A}{2}(\sinh(\eta)-\eta)+c^{te} \tag{12.5.290}$$

As at time $t=0$, we must have $\eta=0$, it follows that the constant must be zero. So finally, we have:

$$\begin{aligned}R&=\frac{A}{2}(\cosh(\eta)-1)\\ t&=\frac{A}{2}(\sinh(\eta)-\eta)\end{aligned} \tag{12.5.291}$$

Remark

Notice that for $\eta=0$, we have $t=0$ but $R\neq 1$ and this wrong value results simply because earlier before we have assumed that for $\eta=0$, R was also equal to zero (but this was obviously an abusive simplification)!

With Maple™ 4.00b we then have by comparing the flat Universe dominated by matter (blue), the flat Universe dominated by radiation (red), the Universe with positive curvature dominated by matter (green), the Universe with positive curvature dominated by radiation (black), the negatively curved Universe dominated by matter (gray):

```
>plot([t^(2/3),t^(1/2),[0.5*(t-sin(t)),0.5*(1-cos(t)),t=0..2*Pi],
[0.5*(1-cos(t)),0.5*sin(t),t=0..2*Pi],[0.5*(sinh(t)-t),0.5*(cosh(t)-1)
,t=0..2*Pi]],t=0...Pi,0..3,color=[blue,red,green,black,gray]);
```

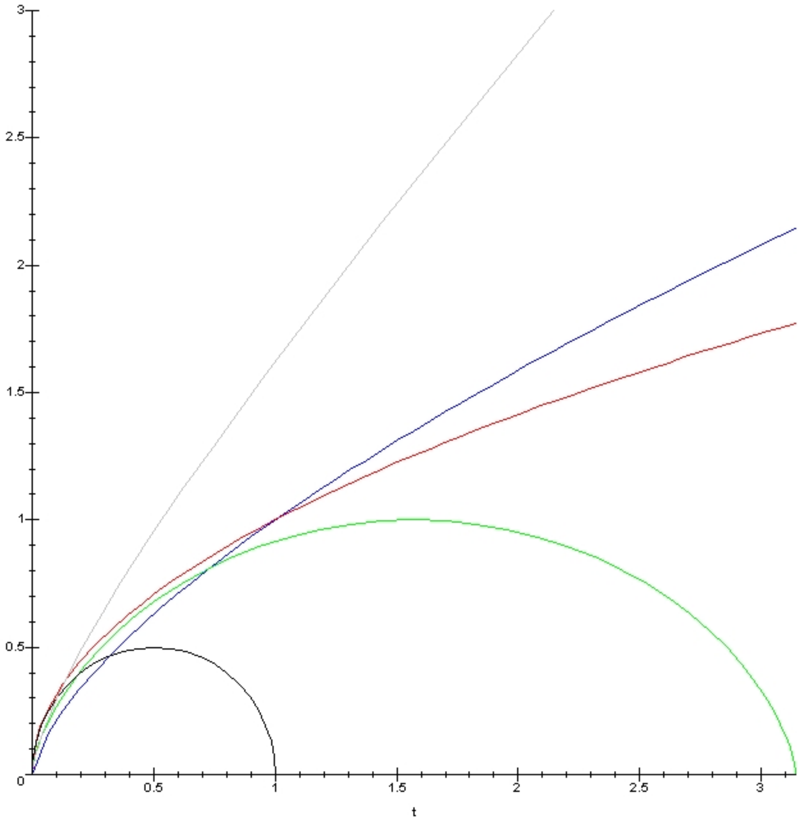


Figure 12.269: Evolution of the R factor for the resulting space configurations studied so far with Maple™ 4.00b

We can therefore observe that for a negative curvature (hyperbolic type), expansion is growing significantly faster than for a flat Universe and this without end.

12.5.3.3.2 Hyperbolic space dominated by radiation

Let us now consider a Universe dominated by radiation. We have proved that in this situation we had:

$$P=\frac{1}{3}\rho_E \tag{12.5.292}$$

and:

$$R^4\rho_E=R_0^4\rho_{E,0}=c^{te} \tag{12.5.293}$$

The first Friedmann equation the becomes:

$$\left(\frac{R'}{R}\right)^2=\frac{8\pi G\rho_E}{3c^2}+\frac{1}{R^2}=\frac{8\pi G\rho_{E,0}}{3c^2}\frac{R_0^4}{R^4}+\frac{1}{R^2} \tag{12.5.294}$$

Then we have:

$$\frac{\mathrm{d}R}{\mathrm{d}t}=\sqrt{\frac{8\pi G\rho_{E,0}R_0^4}{3R^2c^2}+1} \tag{12.5.295}$$

hence:

$$\int \mathrm{d}t=\int \frac{1}{\sqrt{\dfrac{8\pi G\rho_{E,0}R_0^4}{3R^2c^2}+1}}\mathrm{d}R \tag{12.5.296}$$

This is exactly the same integral than that of the spherical universe dominated by matter at the difference that in the root, we have $+1$ instead of -1. We will proceed in the same manner using the comoving time:

$$\mathrm{d}\eta=\frac{\mathrm{d}t}{R} \tag{12.5.297}$$

It comes then:

$$\int \mathrm{d}\eta=\int \frac{1}{\sqrt{\dfrac{8\pi G\rho_{E,0}R_0^4}{3c^2}+R^2}}\mathrm{d}R \tag{12.5.298}$$

Let us write this in the form:

$$\int \mathrm{d}\eta=\int \frac{1}{\sqrt{A+R^2}}\mathrm{d}R \tag{12.5.299}$$

where A is strictly positive. In the section of Differential and Integral Calculus (see page 1534) we have proved how to determine exactly the same primitive (because it is a usual primitive). We have:

$$\eta=\text{arcsinh}\left(\frac{R}{\sqrt{A}}\right)+c^{te} \tag{12.5.300}$$

So that at time $\eta=0$ we have $R=0$, it is necessary that the constant is zero. Therefore:

$$\eta=\text{arcsinh}\left(\frac{A}{\sqrt{A}}\right) \tag{12.5.301}$$

Hence:

$$R=\sqrt{A}\sinh(\eta) \tag{12.5.302}$$

and as:

$$\mathrm{d}\eta=\frac{\mathrm{d}t}{R} \tag{12.5.303}$$

We have:

$$\int \mathrm{d}t=\int R\mathrm{d}\eta=\int \sqrt{A}\sinh(\eta)\mathrm{d}\eta \tag{12.5.304}$$

Which gives:

$$t=\sqrt{A}\cosh(\eta)+c^{te} \tag{12.5.305}$$

As at the time $t=0$, we must have $\eta=0$, it follows that the constant must be equal to $-\sqrt{A}$. So finally, we have:

$$\begin{aligned}R&=\sqrt{A}\sinh(\eta)\\ t&=\sqrt{A}(\cosh(\eta)-1)\end{aligned} \tag{12.5.306}$$

Remark

Notice that for $\eta = 0$, we have $t = 0$ but $R \neq 1$ and this wrong value results simply because earlier before we have assumed that for $\eta = 0$, R was also equal to zero (but this was obviously an abusive simplification)!

With Maple™ 4.00b we then have by comparing the flat Universe dominated by matter (blue), the flat Universe dominated by radiation (red), the Universe with positive curvature dominated by matter (green), the Universe with positive curvature dominated by radiation (black), the Universe with negative curvature dominated by matter (gray), the negative curvature Universe dominated by radiation (brown):

```
>plot([t^(2/3),t^(1/2),[0.5*(t-sin(t)),0.5*(1-cos(t)),t=0..2*Pi],
[0.5*(1-cos(t)),0.5*sin(t),t=0..2*Pi],[0.5*(sinh(t)-t),0.5*(cosh(t)-1)
t=0..2*Pi],[0.5*(cosh(t)-1),0.5*(sinh(t)),t=0..2*Pi]],t=0...Pi,0..3
,color=[blue,red,green,black,grey,brown]);
```

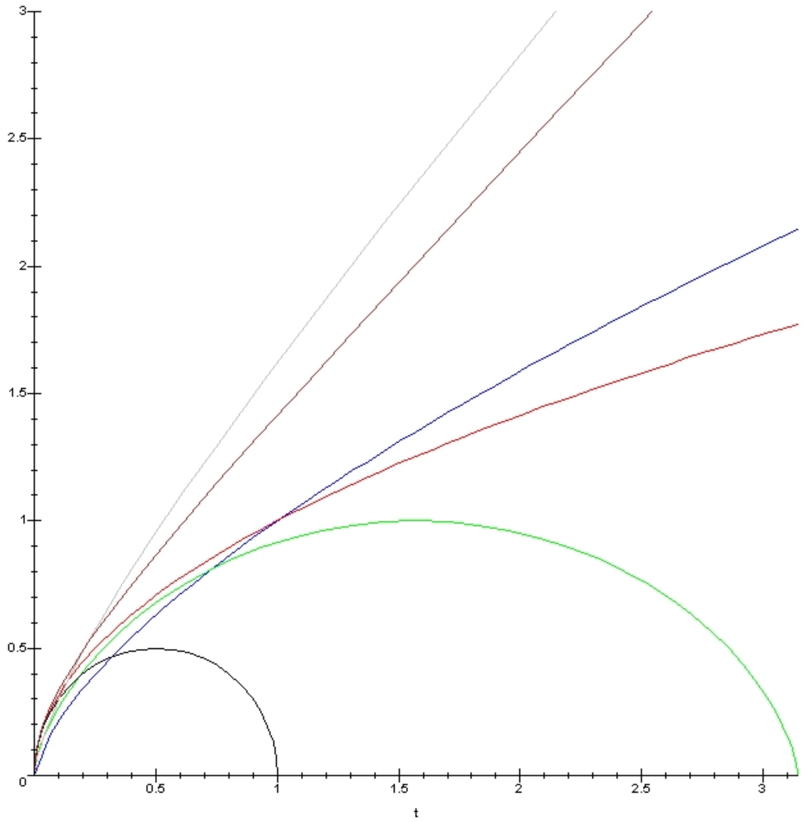

Figure 12.270: **Evolution of the R factor for the resulting space configurations studied so far with Maple™ 4.00b**

We can therefore observe that for a negative curvature (hyperbolic type), the expansion of a Universe dominated by radiation grows slower than a universe dominated by matter (it's a bit intuitive...).

12.5.3.3.3 Hyperbolic space dominated by vacuum

Remember that we have seen earlier above that:

$$\rho(t)\propto R(t)^{-3(1+\omega(T))}\propto\begin{cases}R(t)^{-3} & \text{for } \omega(T)=0 \text{ (pressureless matter (i.e. dust))}\\ R(t)^{-4} & \text{for } \omega(T)=1/3 \text{ (radiation/ultra-relativistic matter)}\\ c^{te} & \text{for } \omega(T)=-1 \text{ (vacuum energy)}\end{cases}\tag{12.5.307}$$

And we also have:

$$R^n\rho=R_0^n\rho_0\Rightarrow\begin{cases}n=0 \text{ for vacuum}\\ n=3 \text{ for matter dominated Universe}\\ n=4 \text{ for radiation dominated Universe}\end{cases}\tag{12.5.308}$$

Hence the case that we want to focus here on is when $\omega(T)=-1$.

We start again from the first Friedmann equation:

$$\left(\frac{R'}{R}\right)^2=\frac{8\pi G\rho}{3}-\frac{k}{R^2}\tag{12.5.309}$$

where again we put here $k=-1$ and we have shown that when vacuum dominates, we had:

$$R^0\rho=R_0^0\rho_0=\rho_{V,0}\tag{12.5.310}$$

Since then:

$$\frac{R'^2}{R^2}=\frac{8\pi G\rho_{V,0}}{3}+\frac{1}{R^2}\tag{12.5.311}$$

and it comes immediately:

$$\frac{\mathrm{d}R}{\mathrm{d}t}=\sqrt{\frac{8\pi G\rho_{V,0}R^2}{3}+1}\tag{12.5.312}$$

Therefore:

$$\int\mathrm{d}t=\int\frac{1}{\sqrt{\dfrac{8\pi G\rho_{V,0}R^2}{3}+1}}\mathrm{d}R\tag{12.5.313}$$

We know have already derived the primitive above during our study of usual primitives in the section of Integral and Differential Calculus at page 1534.

Therefore we get:

$$t=\sqrt{\frac{3}{8\pi G\rho_{V,0}}}\ln\left(\sqrt{\frac{8\pi G\rho_{V,0}}{3}}R+\sqrt{\frac{8\pi G\rho_{V,0}}{3}R^2+1}\right)\tag{12.5.314}$$

Taking the exponential of the above relation, squaring and solving the second degree polynomial relatively to R gives:

$$R=\frac{1}{2}\frac{e^{t^2\left(\frac{8\pi G\rho_{V,0}}{3}\right)^2}-1}{\sqrt{\frac{8\pi G\rho_{V,0}}{3}}e^{t\sqrt{\frac{8\pi G\rho_{V,0}}{3}}}}\tag{12.5.315}$$

The latter has a real solution for all $t \in \mathbb{R}$. With Maple™ 4.00b only for $t > 0$ (it's symmetrical in negative axis if we choose the right integration constant), we get roughly something like the following:

```
>plot(exp(t^2)-1)/exp(t),t=0..3);
```

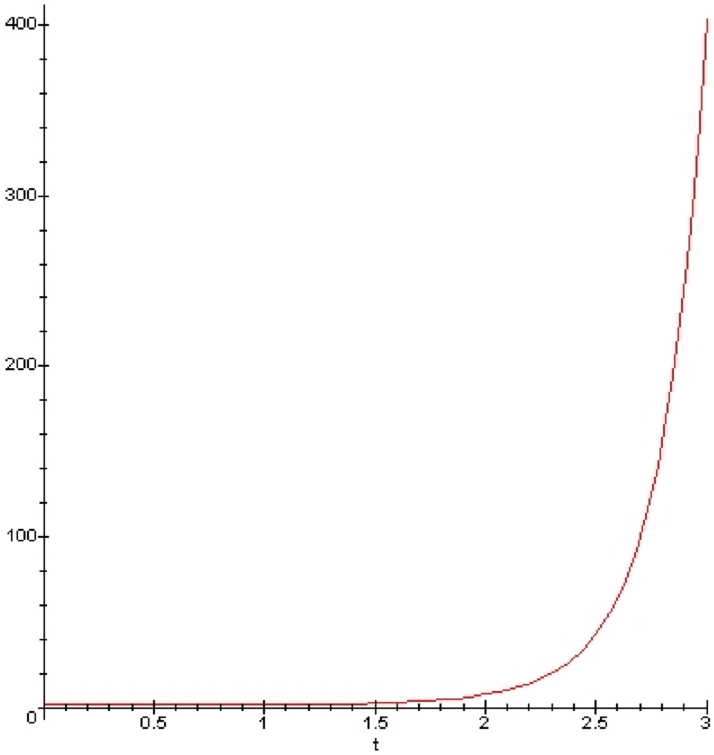

Figure 12.271: **Evolution of R for a hyperbolic space dominated by vacuum**

Finally to summarize a little better all the models seen so far (excepted those dominated by vacuum) with legends we get the following important plot:

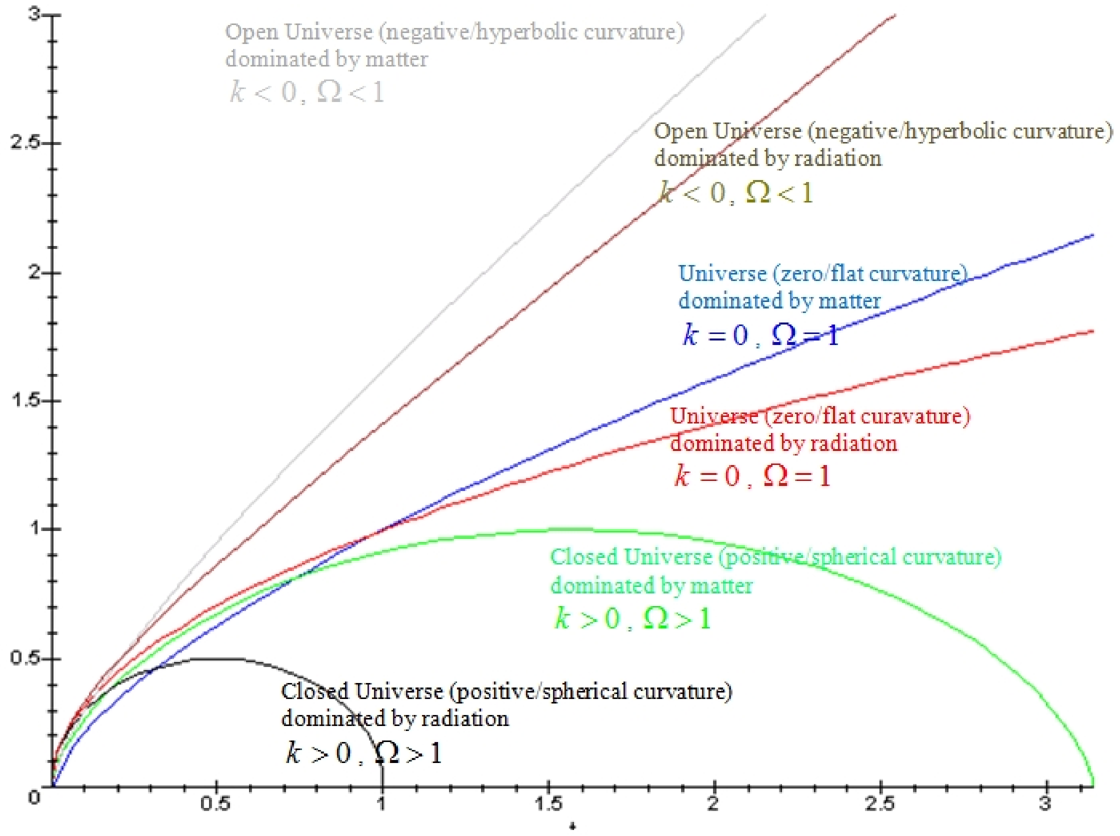

Figure 12.272: Summary of Newtonian Universe models

So we have here above six of the nine models of Universe (the three vacuum solutions are not represented) based on our mathematical assumptions and simplifications.

💣 Caution! Keep in mind that we have the knowledge now with everything that we have seen so far of the following canonical curvature values $k=\{-1,0,+1\}$, of the following typical canonical values of the density parameter $\omega(T)=\{0,1/3,-1/3,1,<-1\}$. Hence in reality there are $3\times 5=15$ different type of dominated universes and not only 9! If we take into account that a universe can contain a mixed of radiation, vacuum, matter, etc. we get in reality $3\times 31=93$ possible mixtures of universes. Obviously we will never study all of them in this textbook!

12.5.4 Observable Universe

We have determined previously a possible interpretation of the current estimate of the age (horizon) of our Universe as being as the inverse of the Hubble parameter that has given us for recall the following value (Hubble time):

$$t_H=\frac{1}{H_0}\cong 13\cdot 10^9\ \text{[year]} \qquad (12.5.316)$$

and the corresponding radius for the Hubble sphere (radius of the observable observer for which every observer is the center)

$$r_{\text{HS}}(t_0)=\frac{c}{H_0}\cong 4430.86\,[\text{Mpc}]\cong 14.4\cdot 10^9\,[\text{light-years}] \tag{12.5.317}$$

And afterwards, under the same strong assumptions[63], we have calculated the Newtonian radius of our Universe (observable part + non-observable part of our Universe)

$$r_{\text{Newt. Universe}}(t_0)\cong 28.8\,[\text{light-years}] \tag{12.5.318}$$

The illustration below typically depicts the fact that the observable Universe is centered on us (assimilated to our Sun) and that the bound of this observable Universe is highly shifted to the red.

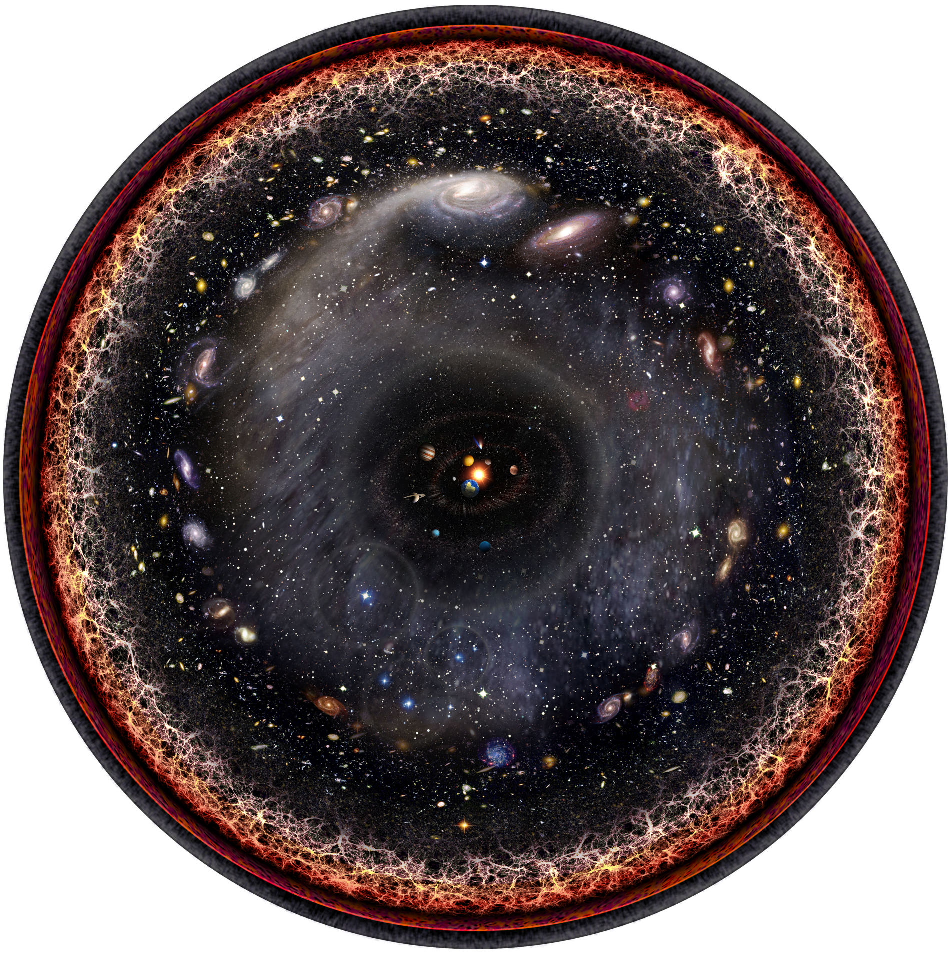

Figure 12.273: Artist's logarithmic scale conception of the observable Universe (source: Wikipedia, author: Pablo Carlos Budassi)

Remarks

R1. It is important to know that popular research articles in cosmology often use the term "Universe" in the sense of "observable Universe".

---

[63] Don't forget that we will see further below a method to estimate the comobile diameter using General Relativity!

R2. People should be more rigorous when speaking of the Universe "age". In fact, we should rather just say that the "horizon of the Universe" is almost 13 billion years. In other words, it is the time that someone would have measured if he has remained an inertial observer (in free fall: not subjected to any force other than gravity) throughout the evolution of the Universe and in a repository such that he would always perceived this Universe as homogeneous and isotropic.

The word "observable" used in this sense does not depend on whether modern technology actually permits detection of radiation from an object in this region (or indeed on whether there is any radiation to detect). It simply indicates that it is possible in principle for light or other signals from the object to reach an observer on Earth. In practice, we can see light only from as far back as the time of photon decoupling in the recombination epoch. That is when particles were first able to emit photons that were not quickly re-absorbed by other particles. Before then, the Universe was filled with a plasma that was opaque to photons. The detection of gravitational waves indicates there is now a possibility of detecting non-light signals from before the recombination epoch.

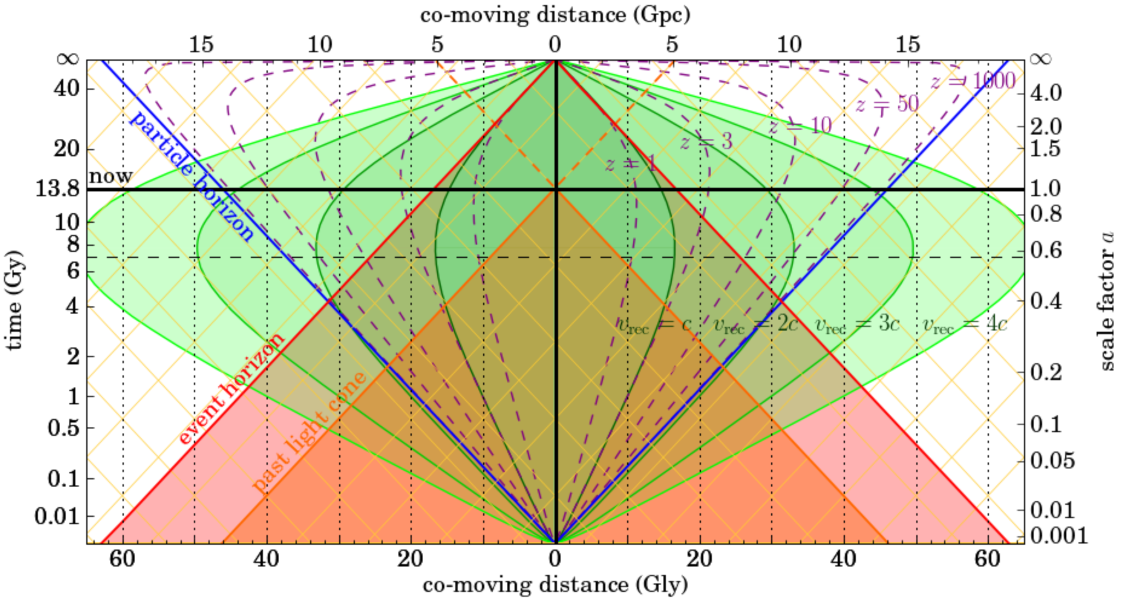
At the beginning of the early 121st century (holocene calendar), we do still do not know if the Universe is finite or infinite, although the majority of theorists currently favour an infinite universe.

The observable Universe is thus composed of all locations that could have affected us since the Big Bang (beware!... despite its name, the Big Bang theory has nothing to say on its start! It merely describes the evolution and the expansion of the Universe).

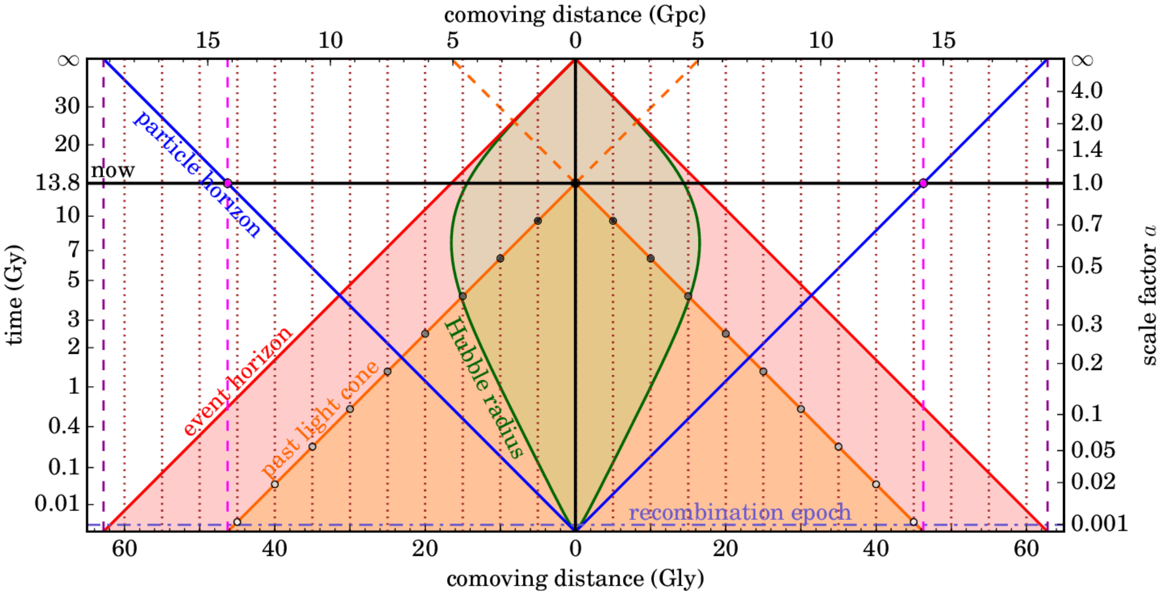
The current size (the "comoving distance") of the observable Universe is larger as we have calculated just earlier before and the corresponding sphere is named the "cosmological sphere".

This value can be obtained by taking the actual most distant visible object which is 13.39 billion light years of Earth (galaxy GN-z11). This will therefore have needed 13.39 billion light years to get away from us, its light will have needed 13.39 billion years to reach us and during the time of light travel, it will have move away of 13.39 billion light years (since objects at cosmological horizon are going at the speed of light). Thus a total of about 40 light billion years (see the detailed mathematical reasoning involving General Relativity further below at page 6048!).

The diagram below (inspired from an article of from Davis & Lineweaver) summarizes many measures of cosmic expansion in a nice, compact, but not necessarily easy-to-understand form (we will give just below a few example on how to read it):



Or a simplified version that has less stuff:



So let us explain how to read the above diagram. First of all, time is going from bottom to top. The thick horizontal black line represents the moment of **now**. Imagine this line moving upwards as time progresses.

The thick vertical black line is *here*. So the intersection of the two thick black lines in the middle is the "*here*-and-**now**".

Distances are measured in terms of the comoving distance, which is basically telling you how far a distant object would be now, if you had a long measuring tape to measure its present-day location.

The area shaded red (marked "past light cone") is all the events that happened in the universe that we could see, up to the moment of now. The boundary of this area is everything in this universe from which light is reaching us right now.

The green curve is the Hubble radius. Regions of space inside it (green shaded area) have recession velocities smaller than c, regions outside have recession velocities bigger than c.

So just for fun, let us pick an object at a comoving distance of 30 gigalightyears (Gly). Look at the dotted vertical line corresponding to 30 [Gly], halfway between the 20 and 40 marks (either side, doesn't matter). It intersects the boundary of the past light cone when the universe was roughly 700 million years old. Good, there were already young galaxies back then. If we were observing such a galaxy today, we'd be seeing it as it appeared when the universe was 700 million years old. Its light would have spent 13.1 billion years traveling before reaching our instruments.

Again look at the dotted vertical line at 30 [Gly] and extend it all the way to the **now** line. What does this tell you about this object? You can read the object's redshift (z) off the diagram: its light is shifted down in frequency by a factor of about 9.

You can also read the object's recession velocity v_{rec}, which is just a little over two times the vacuum speed of light. Yes… faster than light! This recession velocity is based on the rate of change of the scale factor, essentially the Hubble parameter times the comoving distance. The Doppler velocity that one would deduce from the object's redshift yields a value less than the vacuum speed of light (curved space-time is tricky; distances and speeds can be defined in various ways).

Another thing about this diagram is that in addition to the past, it also sketches the future, taking into account the apparent accelerating expansion of the universe. Notice the light red shaded area marked "event horizon". This area contains everything that we will be able to see at our present location, throughout the entire history of the universe, all the way to the infinite future. Things (events) outside this area will never be seen by us, will never influence us.

Note how the dotted line at 30 [Gly] intersects this boundary when the universe is about 5 billion years old. Yes, this means that we will only ever see the first less than 5 billion years of existence of a galaxy at a comoving distance of 30 [Gly]. Over time, light from this galaxy will be redshifted ever more, until it eventually appears to "freeze" and disappears from sight, never appearing to become older than 5 billion years!

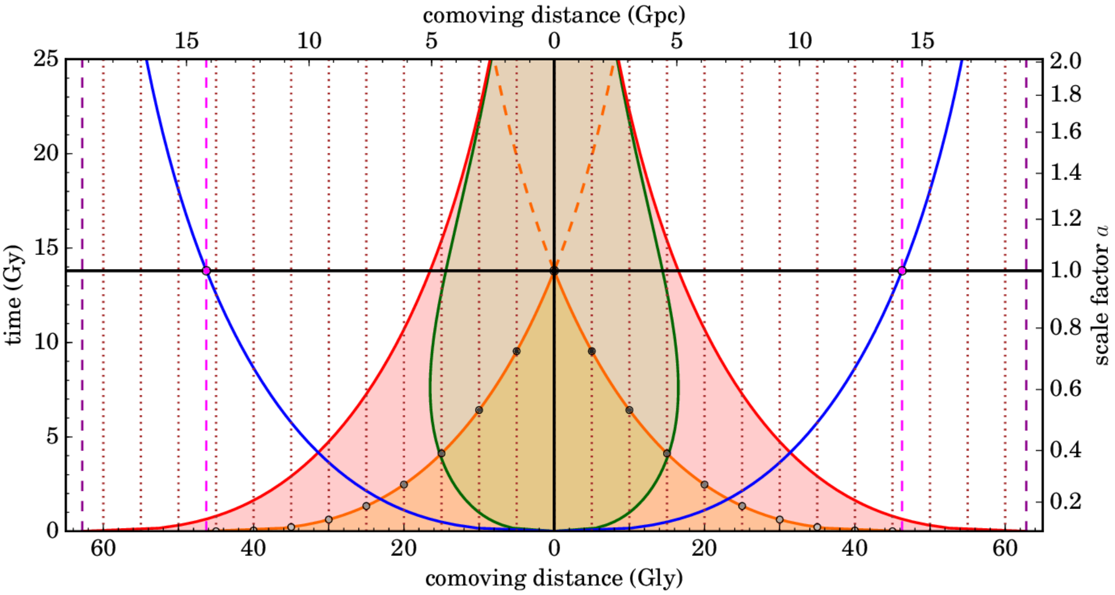
Notice also how the dashed curves marking constant values of redshift bend inward, closer and closer to the *here* location as we approach the infinite future. This is a direct result of accelerating expansion: Things nearer and nearer to us will be caught up in the expansion, accelerating away from our location. Eventually this will stop, of course; cosmic acceleration will not rip apart structures that are gravitationally bound. But we will end up living in a true "island universe" in which nothing is seen at all beyond the largest gravitationally bound structure, the local group of galaxies. Fortunately that won't happen anytime soon; we have many tens of billions of years until then.

Lastly, the particle horizon (blue lines) essentially marks the size of the visible part of the universe at any given time. Notice how the width of the interval marked by the intersection of the now line and the blue lines is identical to the width of the past light cone at the bottom of this diagram. Notice also how the blue lines correspond to infinite redshift.

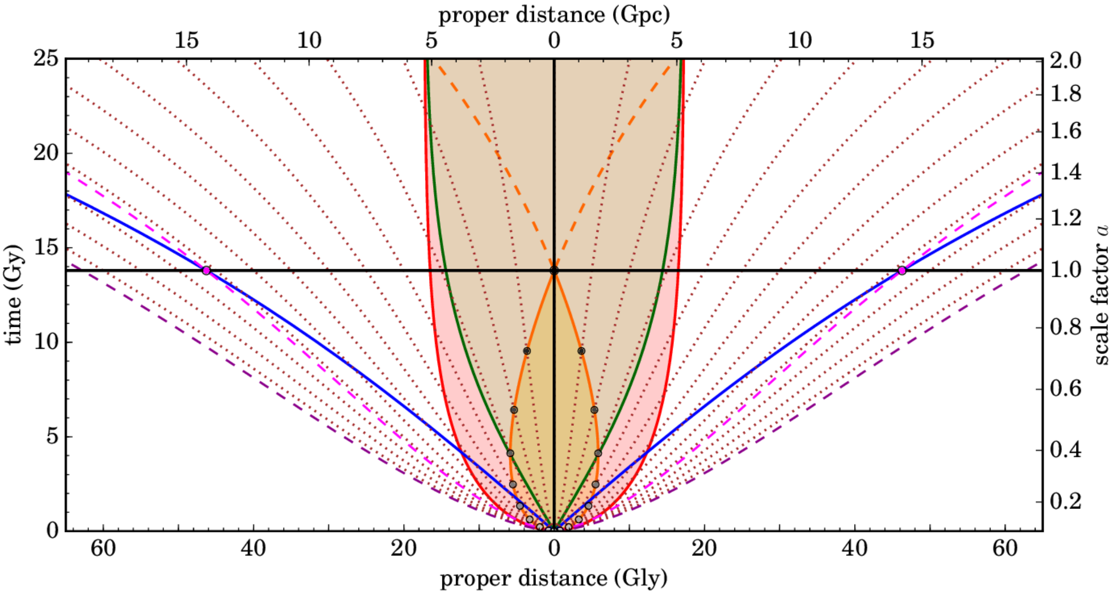
The diagram also shows that we can observe the light from emission events of high z sources (like early events on the worldline of comoving distance $= 30$ [Gly]) even as these sources may not have yet entered the particle horizon and are receding with $v_{\text{rec}} > c$.

The diagram also shows that farthest object whose photons are reaching here-and-now is around 46 billion light years far away now. Event horizon line touches 62 billion light years distance, it means particle horizon will be maximum 62 billion light years, doesn't matter if we will wait upto the infinite time, no photons will ever reach here farther than this distance just like current particle horizon is 46 billion light years.

If we choose linear vertical axis instead the both figure above become (which makes it for most people even more difficult to read):



And as by definition the comoving distance is defined as the proper distance divided by the scale factor, we can also draw the same diagram but based on the proper distance:



As we already said, this diagram is at first sight not an easy read but it is well worth studying.

This observable Universe contains according to today's heuristics estimates (year 12011 according to holocene calendar) about $7 \cdot 10^{22}$ stars, distributed in approximately 10^{10} galaxies, themselves organized into clusters and super-clusters of galaxies. The number of galaxies may be even larger, as the "Hubble Ultra-Deep Field" observed with the Hubble space telescope seems to indicate us.

The Hubble Ultra-Deep Field is an image of a region of the observable universe (equivalent sky area size shown in bottom left corner), near the constellation Fornax. Each spot is a galaxy, consisting of billions of stars. The light from the smallest, most red-shifted galaxies originated nearly 14 billion years ago.

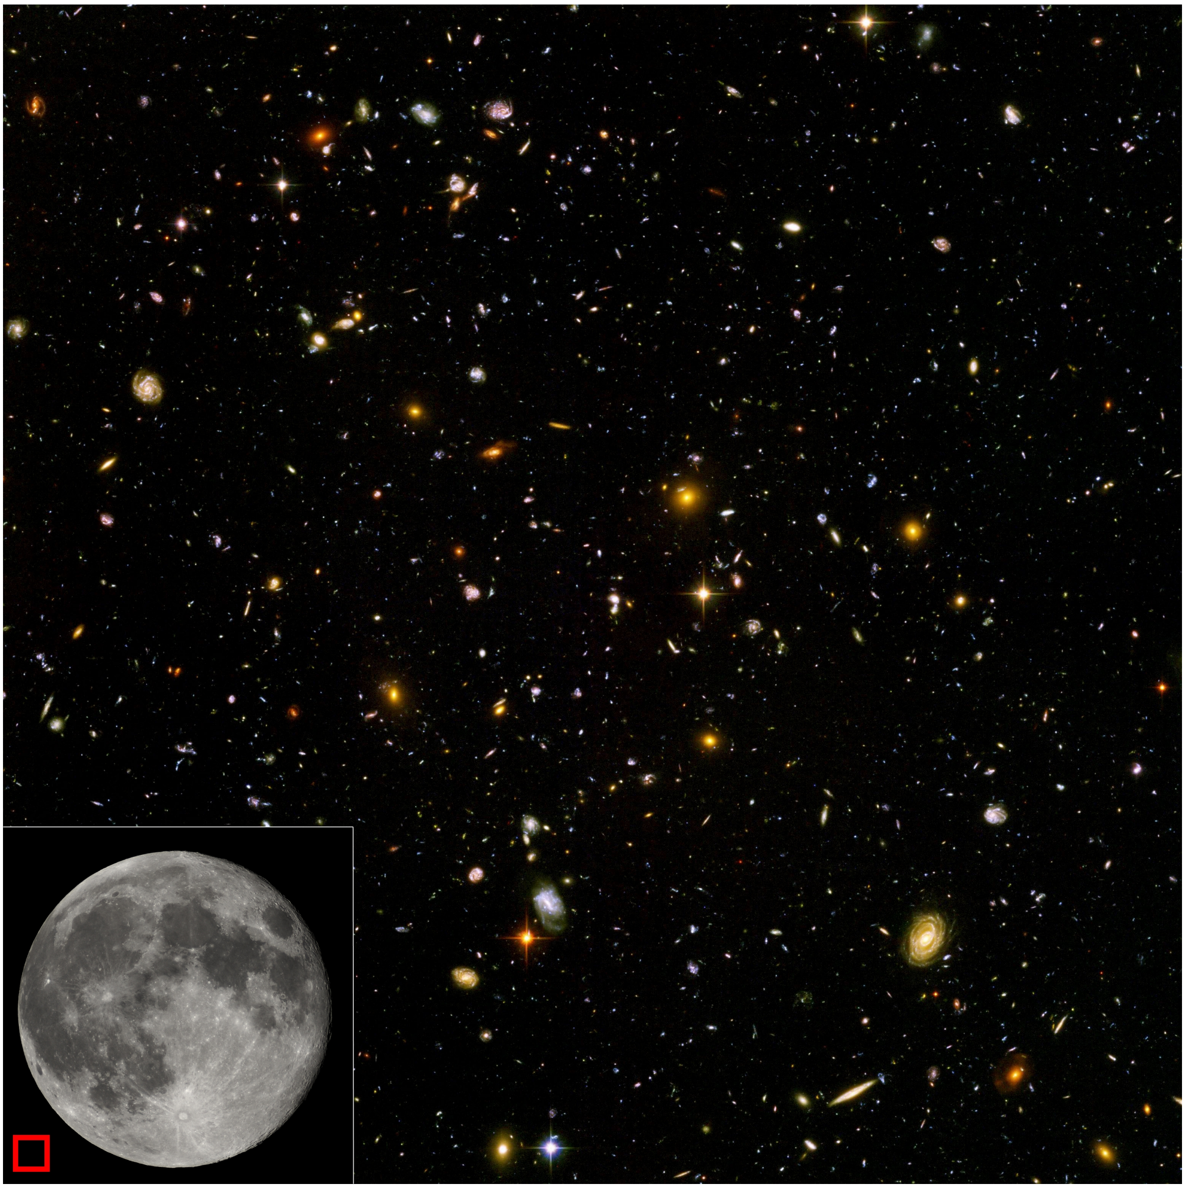


Figure 12.274: Hubble Ultra-Deep field (source: Wikipedia, author: NASA and ESA)

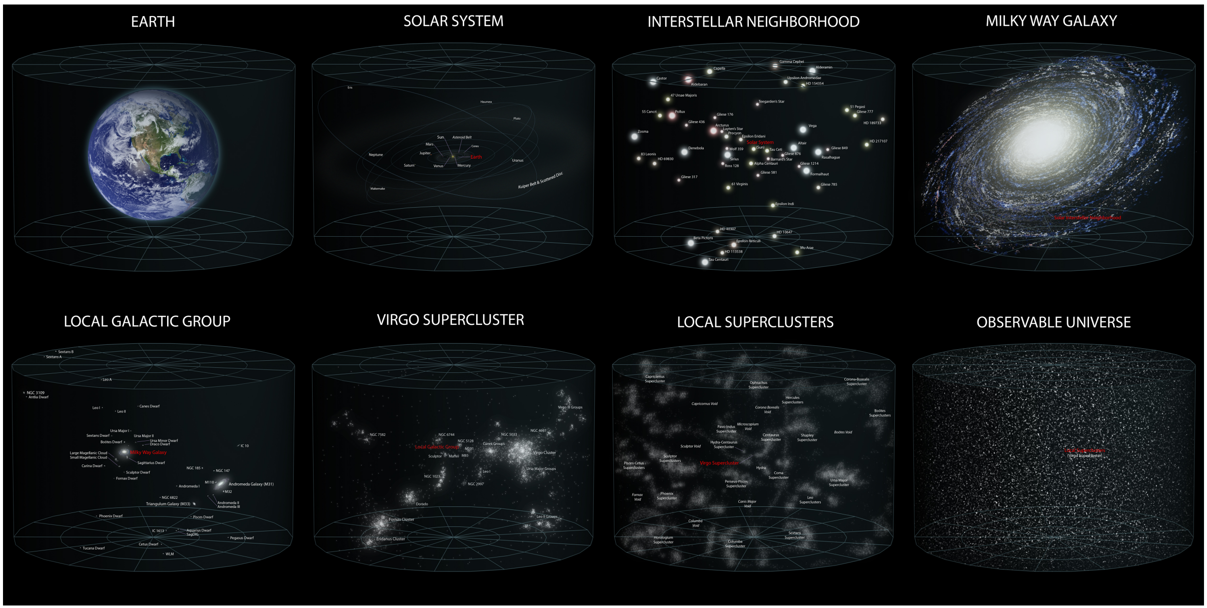
However it is difficult to imagine what that represents. As we found on the Internet some wonderful series of illustrations we would like to share them with the reader before they disappear from the Internet.

First here is a high-resolution summary of various structures you can find at different scales of our Universe (you can considerably zoom in!):



EARTH
SOLAR SYSTEM
INTERSTELLAR NEIGHBORHOOD
MILKY WAY GALAXY
LOCAL GALACTIC GROUP
VIRGO SUPERCLUSTER
LOCAL SUPERCLUSTERS
OBSERVABLE UNIVERSE

Figure 12.275: **Universe scales (source: Wikipedia, author: Andrew Z. Colvin)**

And a more detailed way to discover its structure:

01 The universe to 14 billion light years (the visible Universe as we approximately know it today):

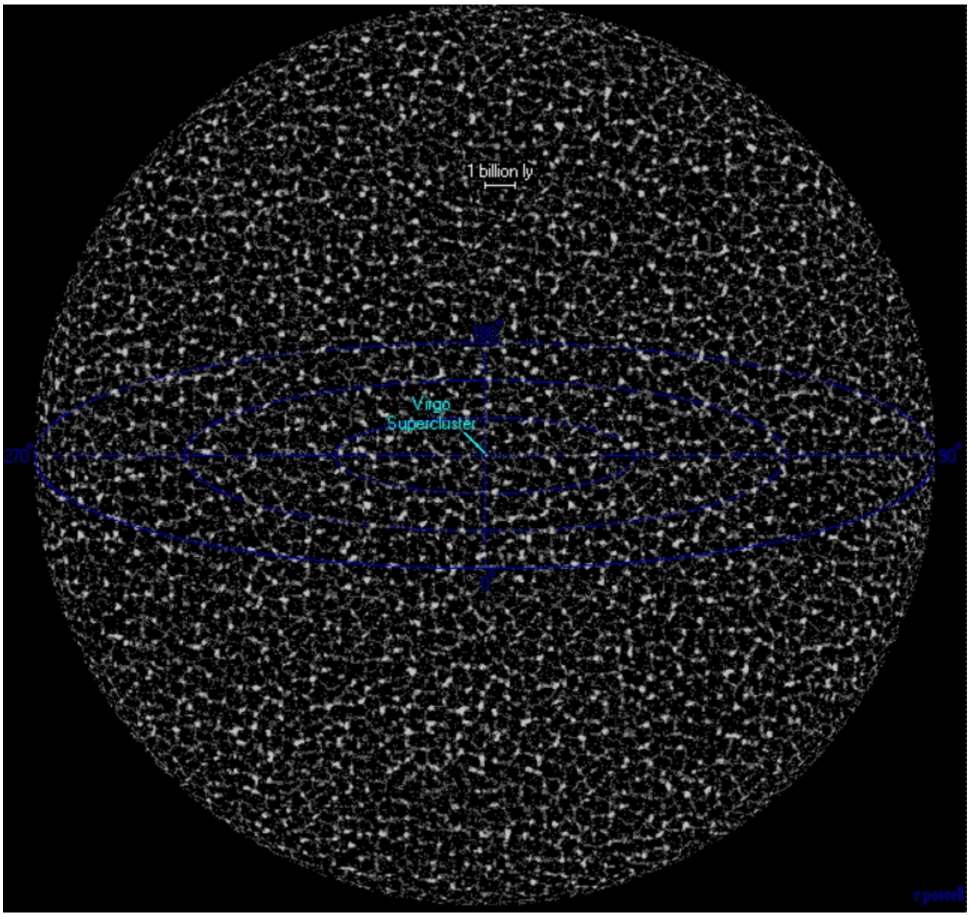


Figure 12.276: **Simplified illustration of the observable Universe**
(source: `http://atunivers.free.fr`, author: Richard Powell)

This illustration attempts to show the entire visible Universe. The galaxies in the universe tend to collect into vast sheets and "supercluster" of galaxies surrounding large vacuums zones, giving the universe a cellular appearance. Because light in the Universe only travel a finite speed, we see objects at the edge of the Universe as when it was very young, there is 14 billion years ago

Some numbers (estimates):

- Number of superclusters in the visible universe: 10 million
- Number of galaxy groups in the visible universe: 25 billion
- Number of large galaxies in the visible universe: 350 billion
- Number of dwarf galaxies in the visible universe: 7 trillion
- Number of stars in the visible universe: 30 billion trillion $(3 \cdot 10^{22})$

(02) After a $\times 14$ zoom we get the Universe withing a 1 billion light years, that is the neighboring superclusters:

r.powell

Figure 12.277: Simplified illustration of the neighboring superclusters (source: `http://atunivers.free.fr`, author: Richard Powell)

Galaxies and clusters of galaxies are not distributed uniformly in the Universe. Instead, they gathered in large clusters, sheets and walls of galaxies separated by large gaps in which few galaxies appear to be. The illustration above shows a number of these super-clusters including the Virgo - a rather small super-cluster of which our Galaxy is part of. The entire map is approximately 7% of the diameter of the visible universe. The galaxies are too small to appear individually on this map, each point there is a group of galaxies.

Some numbers (estimates):

- Number of super-clusters within 1 billion light years: 100
- Number of galaxy groups within 1 billion light years: $240,000$
- Number of large galaxies within 1 billion light years: 3 million
- Number of dwarf galaxies within 1 billion light years: 60 million
- Number of stars within 1 billion light years: $250,000$ trillion

03 After a $\times 10$ zoom we get the Universe within 100 million light years or the Virgo super-cluster:

Figure 12.278: **Simplified illustration of the Virgo supercluster**
(source: `http://atunivers.free.fr`, author: Richard Powell)

Our Galaxy is just one of thousands that lie within 100 million light years. The above illustration shows how galaxies tend to gather in groups, the largest nearby cluster is the Virgo cluster (Virgo), a concentration of several hundred galaxies which dominates the surrounding groups of galaxies. Collectively, all of these groups is known to supercluster Virgo. The second richest cluster in this volume is the Fornax cluster (Fornax), but it is as rich as that of the Virgin. Only bright galaxies are drawn here, our Galaxy is the point at center.

Some numbers (estimates):

- Number of galaxy groups within 100 million light years: 200
- Number of large galaxies within 100 million light years: $2,500$
- Number of dwarf galaxies within 100 million light years: $50,000$
- Number of stars within 100 million light years: 200 trillion

(04) After a $\times 20$ zoom we get the Universe within 5 million light years, that is the Local Group of galaxies:

r.powell

Figure 12.281: Simplified illustration of the Milky Way Galaxy (source: http://atunivers.free.fr, author: Richard Powell)

This map shows the Milky Way as a whole - a spiral galaxy of at least two hundred billion stars. Our Sun (actually a G2V-type star, aka yellow dwarf) is buried deep within the Orion Arm about $26,000$ light years from the center. Toward the center of the galaxy, stars are much closer to each other than at the periphery where we live. Also notice the presence of small globular clusters far outside the galactic plane, and the presence of a neighbouring dwarf galaxy - named "Sagittarius" - which is slowly being swallowed by our own Galaxy.

Some numbers (estimates):

- Number of stars within $50,000$ light years: 200 billion billion

(07) After a $\times 10$ zoom we get the Universe within $5,000$ light years, that is to say the Orion Arm:

Figure 12.282: **Simplified illustration of the Orion Arm**
(source: `http://atunivers.free.fr`**, author: Richard Powell)**

This is a map of our corner of the Milky Way. The Sun is located in the Orion Arm - a fairly small arms compared to the Sagittarius Arm, which is closer to the galactic center. The map shows several stars visible to the naked eye, located far away in the Orion arm. The most notable group of stars is composed of the main stars of the constellation of Orion - from which the spiral arm gets its name. All these stars are bright giant and supergiant stars, thousands of times more luminous than the Sun. The brightest star of the map is Rho Cassiopeia - to $4,000$ light-years from us is just barely visible to the naked eye star, but in reality it is a supergiant $100,000$ times brighter than our Sun.

Some numbers (estimates):

- Number of stars within $5,000$ light years: 600 million

08 After a $\times 20$ zoom we get the Universe within 250 light years, that is to say the solar neighbourhood:

The distances between stars are huge. The distance from the Sun to Proxima Centauri is 4.22 light years, or 40 trillion kilometres. Walk this distance would take a billion years. Even the fastest space probes in this early 121st century (according to holocene calendar) would need 6,000 years to make the trip. There are currently four probes leaving the Solar System - Pioneer 10 and 11 and Voyager 1 and 2 but we will likely lose contact with them within the next two years (if it's not already done when the reader see these lines). The following diagram attempts to show these distances by broadening the scope from the inner Solar System to Alpha Centauri:

12.5.5 Cosmic Microwave Background (CMB)

We have already mentioned the cosmic microwave background earlier above and we have given numerous illustrations of it and the corresponding satellites names and observations related to its experimental study. But let us now give a more detailed picture of the cosmic microwave background to show to the reader that the latter is quite isotropic:

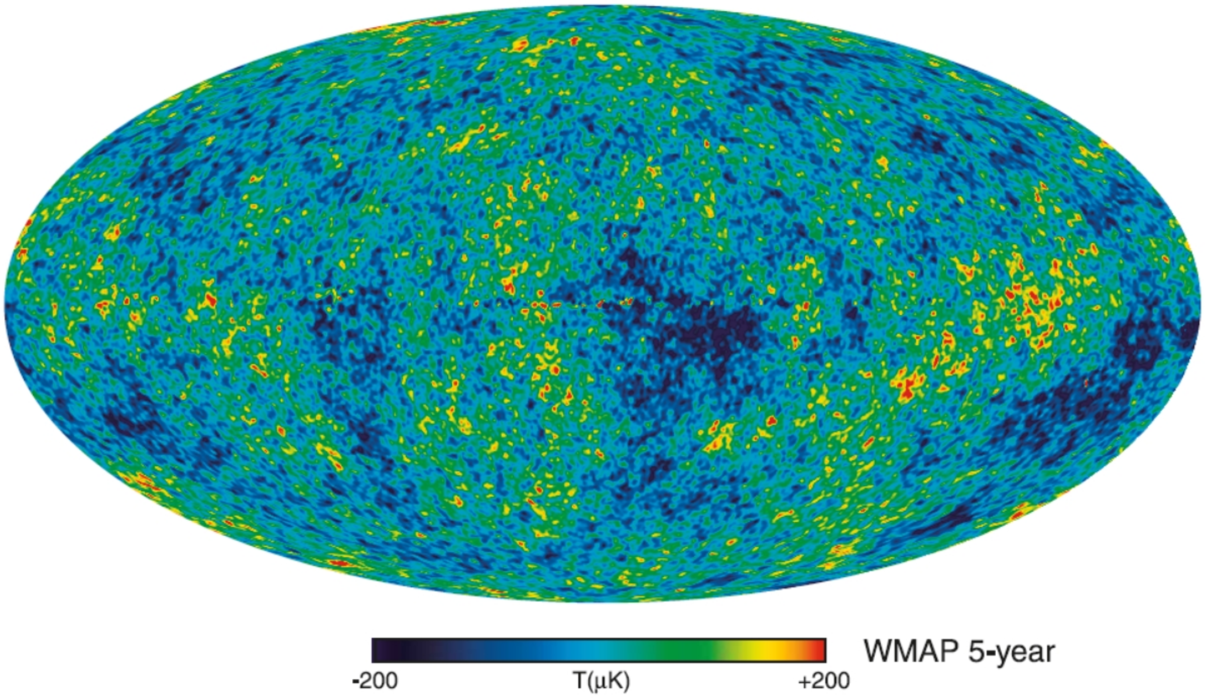

Figure 12.286: **Cosmic microwave background according to WMAP 5-year results (source: NASA/WMAP Science Team)**

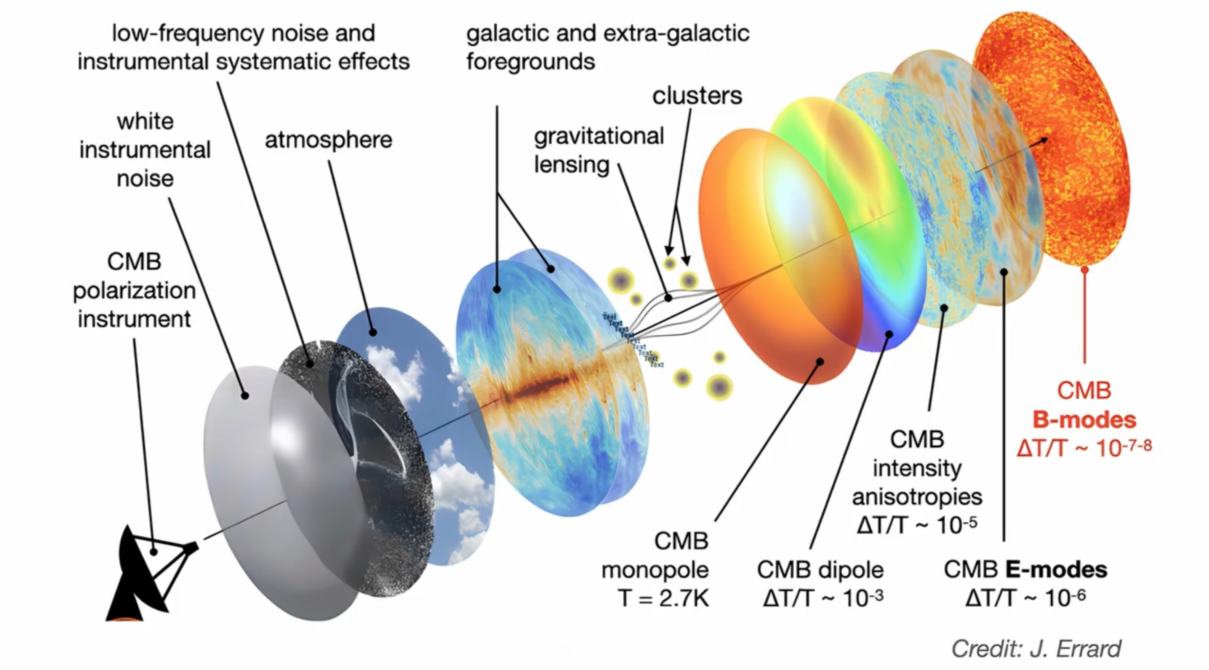
To measure the CMB, astronomers process the incoming signals to remove interference from our Galaxy and other cosmic sources as illustrated below:



low-frequency noise and instrumental systematic effects
galactic and extra-galactic foregrounds
clusters
white instrumental noise
atmosphere
gravitational lensing
CMB polarization instrument
CMB B-modes ΔT/T ~ 10-7-8
CMB intensity anisotropies ΔT/T ~ 10-5
CMB monopole T = 2.7K
CMB dipole ΔT/T ~ 10-3
CMB E-modes ΔT/T ~ 10-6
Credit: J. Errard

Figure 12.287: CMB experiment looking a maze of contaminants (credit: Josquin Errard)

The temperature variations in the CMB are uniform up to about 1 part in $100,000$. So the temperature has range of $2.726\,[\text{K}] \pm 0.00003$ (the root mean square variation is $18\,[\mu\text{K}]$ as reported in [581]). This tells us that the early Universe was rather homogeneous at the decoupling time the CMB was formed. The energy density of the CMB is $0.260\,[\text{eV}\cdot\text{cm}^{-3}$ ($4.17\cdot 10^{-14}\,[\text{J}\cdot\text{m}^{-3}]$) which yields about 411 photons per cubic centimetre.

Remark

A common question is « *How to we know that the WMAP measurement comes from the Big Bang and not something else?* ». First the reader must keep in mind that in Science must of the time we don't know nothing for sure, but we have just different levels of evidence.

First we know that this signal doesn't come from our atmosphere as WMAP is in space... There may be a large amount of diffuse matter in space, that then absorbs starlight from all directions and re-radiates it at a lower temperature! However astronomy has progressed to the point where we have measured the dust in our Galaxy, throughout the Universe, and surrounding the Solar System and we know that at the opposite of the CMB, the dust is not uniformly distributed, is not a perfect absorber (preferentially absorbing blue light and transmitting red light) and the amount of dust actually observed is insufficient to explain this radiation (the CMB signal is about 100 times larger than the background signal).

But maybe there's something out there, far beyond the galaxies we know, that's emitting an ultra-distant source of light (and therefore red-shifted!). After all, stars and galaxies appear to be everywhere, and the Sun is almost a perfect blackbody radiator. And the answer is in the question! Stars aren't perfect blackbody but the CMB is an almost perfect one as depicted in the plot below:

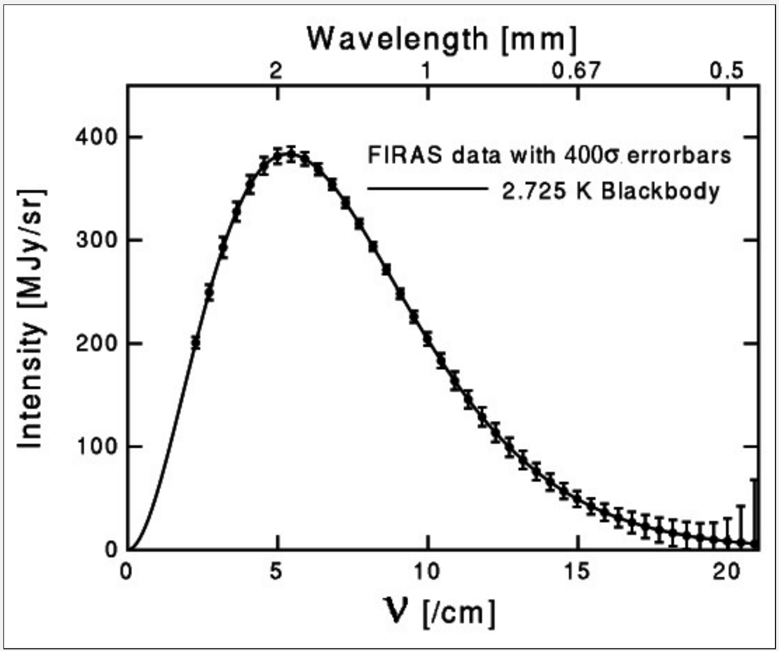


Figure 12.288: **FIRAS CMB Black Body radiation spectrum**

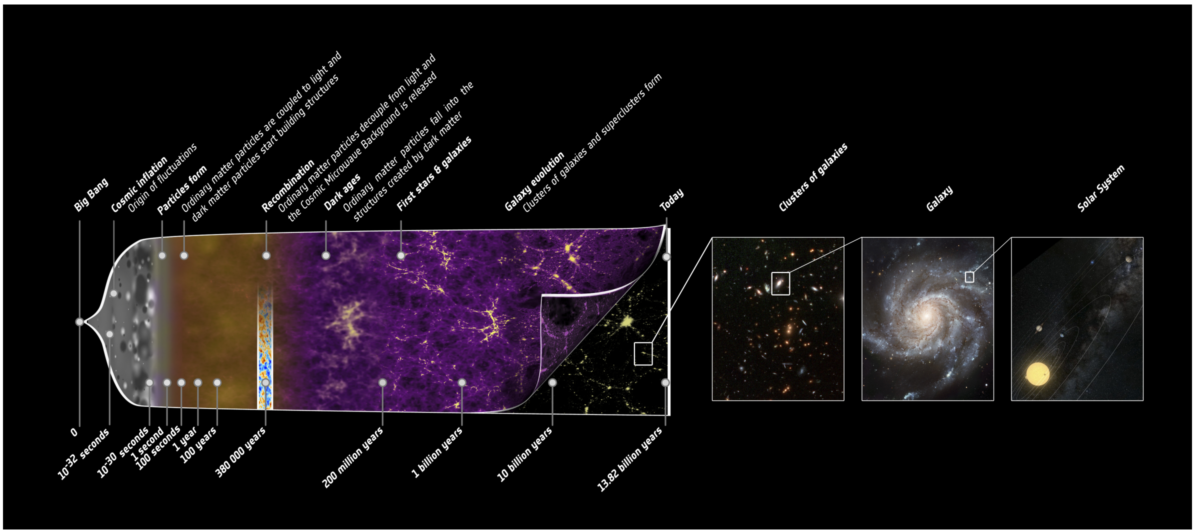
It isn't the atmosphere. It seems it isn't dust. It seems it isn't starlight. It seems it isn't the Oort cloud bodies (that should be at the order of 10 [K]). It isn't the heliopause (as the latter has an asymmetry because of Sun's directional movement). This background of radiation, more perfectly a blackbody in its spectrum than anything else in the Universe, must have its origin in a hot, dense state that existed billions of years ago... So it may very likely be the Big Bang (but without absolute certitude!).

The purpose now will be in what follows to have a mathematical approach of the cosmic microwave background!

12.5.5.1 Decoupling time

The existence and properties of the cosmic radiation discovered experimentally by Arno Penzias and Robert Woodrow Wilson in 11964 (holocene calendar) but theoretically by Ralph Apher in 11948 (holocene calendar) were mainly due to the two physical phenomena that we will now describe in broad outline.

The expansion of the Universe has for consequence that after the fantastically high values that have reigned immediately after the Big Bang it is gradual cooling! When it reaches about $3,000$ [K] occurs the first of two crucial phenomena that interest us here: the radiation, which until then was in thermal equilibrium with the material particles practically ceases to interact with them and became independent. In the "standard model" of evolution of the Universe, we calculate that this crucial moment is situated approximately $300,000$ years after the Big Bang (see the proofs further below).



Big Bang
Cosmic inflation
Origin of fluctuations
Particles form
Ordinary matter particles are coupled to light and dark matter particles start building structures
Recombination
Ordinary matter particles decouple from light and the Cosmic Microwave Background is released

13.82 billion years

Figure 12.289: 2D illustration of (speculated) Universe past history following 121st century hypothesis (source: ESA)

We can first qualitatively understand the physical reasons for this (further below we will approach this with maths stuff!). Shortly before, when for example the temperature was $100,000$ [K], the Universe contained mostly photons, electrons and bare atomic nuclei (mostly protons, and, to a lesser extent, α particles, helium 4 nuclei). The temperature was too high so that the electrons and nuclei may form stable atoms. The interaction between the photons and charged particles (mainly electrons, the lighter of them) is sufficiently intense, and the density of the latter was then sufficiently strong, so that the photons were continuously diffused, transmitted and absorbed. Despite its expansion, the Universe was at every moment at equilibrium; its temperature T was consistently well defined, although decreasing over time, the photon energy, that is to say the pulse of radiation, was therefore distributed according to Planck's law for this temperature T (see section Thermodynamics page 3719)!

The temperature decrease then permit the formation of atoms from the electrons and nuclei. This process led to a rapid drop in average cross section of interaction between photons and material particles (mainly due to the disappearance of free electrons), so that the Universe became transparent to photons. A quantitative assessment of the characteristics of the phenomenon is this decoupling occurred when the temperature dropped to $3,000$ [K] (see the simple mathematical approach further below).

At the moment of decoupling, the volume density of the radiation energy is distributed in the pulsations spectrum according to Planck's law (see section Thermodynamics page 3719):

$$R(\omega,T)=\frac{2\hbar\omega^3}{\pi c^3}\frac{1}{e^{\frac{\hbar\omega}{kT}}-1}\;[\mathrm{J}\cdot\mathrm{s}\cdot\mathrm{m}^{-3}] \qquad (12.5.319)$$

where we assume that T is the temperature ($3,000$ [K] approximately - ionization temperature of the simplest atoms[64]) at the moment of decoupling. This distribution will then evolve under the influence of the expansion of the Universe.

Let us consider the photons located at time t in the volume $4/3r^3\cong r^3$, and whose pulsation ω

---

[64] we will see further the detail treatment of where this value comes from.

with a variation $\mathrm{d}\omega$. Their number is then using previous relation equal to:

$$\mathrm{d}N\cong\frac{r^3}{\hbar\omega}R(\omega,T)=r^3\frac{2\omega^2}{\pi c^3}\frac{\omega^2\mathrm{d}\omega}{e^{\frac{\hbar\omega}{kT}}-1} \tag{12.5.320}$$

where we assume that T is the temperature ($3,000$ [K] approximately - ionization temperature of the simplest atoms) at the moment of decoupling. This distribution will then evolve under the influence of the expansion of the Universe.

As there is no absorption or emission of photons at this temperature (it is a hypothesis but as experimental measurements seem to confirm this model...), this number will remain constant. But because of the expansion of the Universe, these photons constant number will occupy a larger volume, and gain greater wavelength λ (following the expansion of the structure of space due to the positive value of the Hubble parameter) that is to say, a rather smaller pulsation ω (the equivalent of the Doppler effect). To clarify, let us consider the situation at a further time t'. All lengths of the Universe have increased between, between t and t', by the same scaling factor F following the Hubble's law: the chosen radius r of our previous selected sphere volume has therefore become obviously:

$$r'=Fr \tag{12.5.321}$$

and the wavelength of the photons considered:

$$\lambda'=F\lambda \tag{12.5.322}$$

so that their pulsation is equal at the instant t' to:

$$\omega^{=}\frac{2\pi c'}{\lambda'}=\frac{\omega}{F} \tag{12.5.323}$$

Therefore the energy contained at this time in the volume $V\cong r'^3$ and in the pulsation range $(\omega',\omega'+\mathrm{d}\omega')$ is given obviously by:

$$r'^3R'(\omega',T')\mathrm{d}\omega' \tag{12.5.324}$$

More explicitly:

$$r'^3R'(\omega',T')\mathrm{d}\omega=\hbar\omega'(\mathrm{d}N)=\hbar\omega'\left(\frac{2r^3}{\pi c^3}\frac{\omega^2\mathrm{d}\omega}{e^{\frac{\hbar\omega}{kT}}-1}\right) \tag{12.5.325}$$

The volumetric energy density $R'(\omega',T')\mathrm{d}\omega'$ at time t', for the pulsation range $(\omega',\omega'+\mathrm{d}\omega')$, is then written:

$$R'(\omega',T')\mathrm{d}\omega'=\hbar\omega'\frac{(\mathrm{d}N)}{r'^3}=\hbar\omega'\left(\frac{2r^3}{r'^3\pi c^3}\frac{\omega^2\mathrm{d}\omega}{e^{\frac{\hbar\omega}{kT}}-1}\right)=\hbar\omega'\left(\frac{2}{F^3\pi c^3}\frac{F\omega'^2F\mathrm{d}\omega'}{e^{\frac{\hbar F\omega'}{kT}}-1}\right) \tag{12.5.326}$$

It follows that the spectral energy distribution is still at the instant t' that of the black-body:

$$R'(\omega',T')=\frac{2\hbar\omega'^3}{\pi c^3}\frac{1}{e^{\frac{\hbar F\omega'}{kT}}-1}=\frac{2\hbar\omega'^3}{\pi c^3}\frac{1}{e^{\frac{\hbar\omega'}{kT'}}-1} \tag{12.5.327}$$

where the corresponding temperature T' is immediately such that:

$$T'=\frac{T}{F} \tag{12.5.328}$$

that is more often written:

$$\boxed{F=\frac{T_{\text{dec}}}{T_{\text{CMB}}}} \quad (12.5.329)$$

Thus, after decoupling with matter, the cosmic radiation evolves maintaining the distribution of a black-body whose temperature decreases regularly in the same proportion as the distances are increased during the expansion of the Universe.

From the moment of decoupling, the F factor of scale is very close to $1,000$ since from to the estimated $3,000$ [K] to go to the 2.7 [K] measured today there is a factor of:

$$F=\frac{T_{\text{dec}}}{T_{\text{CMB}}}=\frac{3,000}{2.7}\cong 1,100 \quad (12.5.330)$$

also named "recombination redshift".

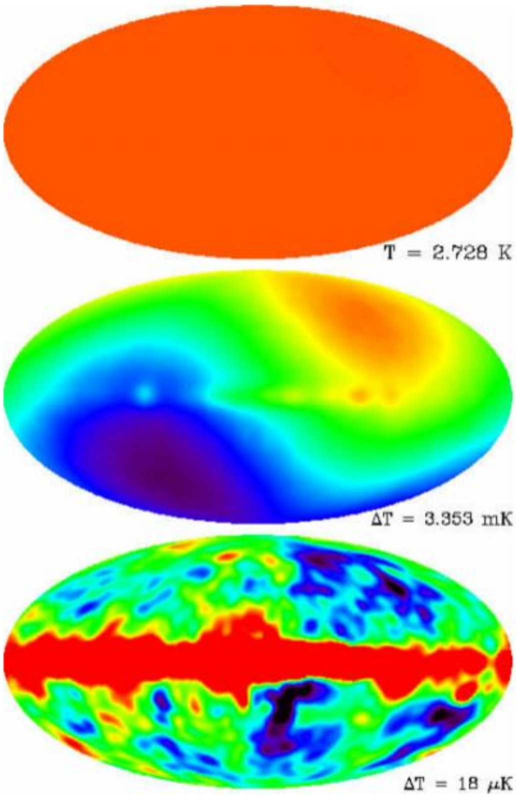

Figure 12.290: **Radiation is isotropic to 10^{-5} in temperature**

This value of approximately $1,000$ allows us, from the Friedmann-Lemaître model we have introduced earlier above, to easily calculate at what time (horizon) of the Universe this decoupling occurred.

If we consider a radiation dominate flat Universe we have proved roughly that the scale factor $R(t)$ was proportional to the $t^{2/3}$:

$$R(t)\propto t^{2/3} \quad (12.5.331)$$

So clearly we have the age ratio of:

$$1100\propto t^{2/3} \quad (12.5.332)$$

That is:

$$t \cong 1,100^{3/2} \cong 36,482 \qquad (12.5.333)$$

So to get the age of the universe at $z = 1100$ we would therefore have to divide the age now, by the factor $36,482$. This gives:

$$\frac{13.700 \pm 0.021 \cdot 10^9 \text{ [years]}}{36,482} \cong 378,241 \text{ [years]} \qquad (12.5.334)$$

Or more generally:

$$\boxed{t_{\text{decoupling}} = H_0^{-1}\left(\frac{T_{\text{dec}}}{T_{\text{CMB}}}\right)^{-3/2}} \qquad (12.5.335)$$

Thus we find a value of approximately $380,000$ years. This is according to what most textbooks gives without proof.

Let us focus now on a special and important needed value for the next sub-section (recombination temperature)!

The energy density associated with the blackbody radiation of temperature T is as we know given by the Stefan-Boltzmann law (see section Thermodynamics page 3706):

$$\rho_{\gamma,0}(T) = \sigma_{\text{S.B.}} T_0^4 = 0.262 \, [\text{MeV} \cdot \text{m}^{-3}] \qquad (12.5.336)$$

and the mean energy per photon is given by $\sim kT$. Therefore, the number density of blackbody photons for $T = 2.7$ [K] is given by:

$$n_\gamma \cong \frac{\frac{4\sigma}{c} T_0^4}{kT} = 370 \, [\text{photons} \cdot \text{cm}^{-3}] \qquad (12.5.337)$$

The number density of baryons can be expressed by ρ_m/m_p, where ρ_m is the mass density of the observed Universe and m_p is the mass of the proton $(1.66 \cdot 10^{-24} \, [\text{g}])$. CMB measurements show that the baryonic mean density is $\rho_m \cong 4.2 \cdot 10^{-31} \, [\text{g} \cdot \text{cm}^{-3}]$ (roughly 5% of the critical density). This leads to the value of $\sim 2 \cdot 10^{-7}$ for the number density of baryons.

Then we have the photon to baryon[65] ratio (that is sometimes defined as the opposite ratio depending on the textbook...):

$$\eta = \frac{\rho_r}{\rho_m} = \frac{\text{photons}}{\text{baryons}} = \frac{n_\gamma}{n_b} \cong \frac{370}{2 \cdot 10^{-7}} \cong 1.85 \cdot 10^9 \qquad (12.5.338)$$

In other words, for each baryon in the Universe there is 10^{10} photons. This estimate is in agreement with the precise value of the photon to baryon ratio $1.64 \cdot 10^9$ derived with the WMAP. Since the photon number and the baryon number seems to be conserved, the photon-baryon ratio stays constant as the Universe expands.

The Planck satellite 95% confidence interval (year 12017 according to holocene calendar) for η is given by:

$$1.61 \cdot 10^9 \leq \eta \leq 1.69 \cdot 10^9 \qquad (12.5.339)$$

---

[65] A baryon is a composite subatomic particle made up of three quarks (a triquark, as distinct from mesons, which are composed of one quark and one antiquark). Baryons and mesons belong to the hadron family of particles, which are the quark-based particles.

Remark

The photon to baryon ratio is estimated and measured. It's partially measured/estimated from the observation of the numbers and average sizes of galaxies and stars, and the density of interstellar matter, and some other baryonic matter. The number density of photons is very well estimated to be about 413 photons per cm^3.

12.5.5.2 Matter/Photon decoupling (recombination temperature)

Now let us see how we can get an approximation of the famous $3,000$ [K] that we see in almost all textbooks for the recombination temperature!

As we have seen above, the early universe may have been hot. So hot maybe that nuclei boiled. The great thermal energy of the universe overwhelmed the confining efforts of the nuclear and electromagnetic forces, and droves of fundamental particles - quarks, gluons, leptons, photons - bounced and jostled in a tightly-coupled plasma. The Universe, however, has a built-in cooling mechanism: expansion. Matter particles dilute and photon wavelengths stretch as the universe expands in a process named "redshift". Soon, protons and neutrons condense out of the plasma as the strong force overcomes the waning thermal wanderings of quarks and gluons. Over the next ten minutes, these nucleons join to form nuclei of deuterium, helium, and other light elements. The protons and nuclei, however, are naked - it's still too hot for electrons to join them in the formation of neutral atoms. The universe will remain in this ionized state for the next few hundred thousand years[66].

The thing about ionized plasma, is that photons have a hard time getting around: there is no shortage of charged particles ready for a collision. The average distance travelled by a photon before collisions is the mean free path (see section Continuum Mechanics page 3925):

$$\gamma_\lambda=(n\sigma)^{-1} \tag{12.5.340}$$

determined by the number density of the charge-carriers, n, and the scattering cross-section, σ. To get a feel for just how waded up everything was maybe in the early Universe, let's find the mean free path of photons when the universe was one second old, at a torrid $T=10^{10}$ [K]. This is the epoch of said of "nucleosynthesis", when protons and neutrons are supposed to fused to form the light nuclei.

---

Though we are technically in the realm of Compton scattering (see section Atomistic page 5096), $T > m_e$, the Thomson scattering cross-section (see section Atomistic page 5100) will suffice for an order-of-magnitude estimate: $\sigma_T \cong 6.652 \cdot 10^{-29}\,[\mathrm{m}^2]$, where σ_T for reminder is proportional to e^4/m_e^4. As for the charge-carrier density, we can safely ignore everything except the electrons: though the supposed charge neutrality of the universe requires that the densities of free electrons and protons balance, $n_e = n_p$, scattering off the much heavier protons is suppressed by a factor of a million relative to electrons (owing to the factor $1/m_e^4$ in σ_T)[67]

It's safe to treat the electrons as radiation (they are still quite hot, about the temperature of a supernova). To get the number density, we need to integrate the Fermi-Dirac distribution function (see section Statistical Mechanics page 3571):

$$f_{\text{FD}}(E,T,\mu)=\frac{1}{e^{\frac{E-\mu}{kT}}+1} \tag{12.5.342}$$

over the full phase space in the relativistic limit, $(T \gg \mu, m)$. For this we will use a similar approach to that we used during our study of semi-conductors that had lead us to (see page 4291):

$$\rho(E)\cong\frac{1}{2\pi^2}\left(\frac{2m_e}{\hbar^2}\right)^{3/2}\int\limits_{E_0}^{+\infty}\frac{(E-E_0)^{1/2}}{\exp\left(\frac{E-\mu}{kT}\right)+1}\mathrm{d}E \tag{12.5.343}$$

But however with an important difference. Instead of taking:

$$k\cong\sqrt{(E-E_0)\frac{2m_e}{\hbar^2}} \tag{12.5.344}$$

as we did for the semi-conductor. We take now:

$$k=\frac{p^2}{\hbar^2}=\frac{E^2-m_e^2c^4}{c^2\hbar^2} \tag{12.5.345}$$

What lead us to (still see page 4291):

$$\frac{N(k)}{V}=\frac{k^3}{3\pi^2}=\frac{1}{3\pi^2}\frac{(E^2-m_e^2c^4)^{3/2}}{c^3\hbar^3}=\frac{N(E)}{V} \tag{12.5.346}$$

And therefore:

$$D(E)=\frac{1}{V}\frac{\mathrm{d}N(E)}{\mathrm{d}E}=\frac{\mathrm{d}n(E)}{\mathrm{d}E}=\frac{(E^2-m_e^2c^4)^{1/2}E}{c^3\hbar^3} \tag{12.5.347}$$

And if $E \gg m_e$ then:

$$D(E)\cong\frac{E^2}{c^3\hbar^3} \tag{12.5.348}$$

Hence the above integral becomes (changing to lower boundary to the case that concerns us here):

$$\rho(E)\cong\frac{1}{c^3\hbar^3}\int\limits_{0}^{+\infty}\frac{E^2}{\exp\left(\frac{E-\mu}{kT}\right)+1}\mathrm{d}E \tag{12.5.349}$$

and in the approximation $T \gg \mu, m$:

$$\rho(E)\cong\frac{1}{c^3\hbar^3}\int\limits_{0}^{+\infty}\frac{E^2}{\exp\left(\frac{E}{kT}\right)+1}\mathrm{d}E \tag{12.5.350}$$

---

[67] And the even heavier and more dilute deuterium, helium, and lithium nuclei can be likewise ignored.

Integral that can be found in some textbooks in natural units. Therefore:

$$\rho(E) \cong \int\limits_{0}^{+\infty} \frac{E^2}{\exp\left(\frac{E}{T}\right)+1}\mathrm{d}E \tag{12.5.351}$$

Back to S.I. units that lead us finally to:

$$n_e \cong g_e \frac{1}{c^3\hbar^3} \int\limits_{0}^{+\infty} \frac{E^2}{\exp\left(\frac{E}{kT}\right)+1}\mathrm{d}E \tag{12.5.352}$$

where $g_e = 2$ is the fermion degeneracy.

The integral:

$$\int\limits_{0}^{+\infty} \frac{E^2}{\exp\left(\frac{E}{kT}\right)+1}\mathrm{d}E \tag{12.5.353}$$

can be solved via geometric series expansion and some low-level tricks. First, substitute $x = E/kT$ giving:

$$I = (kT)^3 \int\limits_{0}^{+\infty} \frac{x^2}{e^x+1}\mathrm{d}x \tag{12.5.354}$$

The idea is to use the binomial theorem for negative integer exponents (see section Calculus page 1707) involving the exponential:

$$I = (kT)^3 \int\limits_{0}^{+\infty} e^{-x}(1+e^{-x})^{-1}x^2\mathrm{d}x = (kT)^3 \int\limits_{0}^{+\infty} \left[\sum_{k=0}^{+\infty}(-1)^k e^{-(k+1)x}\right] x^2\mathrm{d}x \tag{12.5.355}$$

After another change of variables, $y = (k+1)x$:

$$I = (kT)^3 \sum_{k=0}^{+\infty}(-1)^k \frac{1}{(k+1)^3} \int\limits_{0}^{+\infty} y^2 e^{-y}\mathrm{d}y \tag{12.5.356}$$

The keen eye might recognize $\int\limits_{0}^{+\infty} y^2 e^{-y}\mathrm{d}y$ as the gamma function (see section Differential and Integral Calculus page 1574), $\Gamma(3) = (3-1)! = 2$. This, together with a slight nudge to the bottom limit of the summation we can rewrite things as:

$$I = -(kT)^3\Gamma(3) \sum_{k=1}^{+\infty} \frac{(-1)^k}{k^3} \tag{12.5.357}$$

To get rid of the annoying $(-1)^k$ term, we break the summation up into an even and an odd part, and then rework things to get two full summations back:

$$I = -(kT)^3\Gamma(3)\left(\sum_{k}^{\text{even}}\frac{1}{k^3} - \sum_{k}^{\text{odd}}\frac{1}{k^3}\right) = -(kT)^3\Gamma(3)\left(\frac{2}{2^3}\sum_{l=1}^{+\infty}\frac{1}{l^3} - \sum_{k=1}^{+\infty}\frac{1}{k^3}\right) \tag{12.5.358}$$

After the dust settles, we see that two copies of the Riemann zeta function have emerged, $\zeta(3) = \sum_k 1/k^3$ (see section Sequences and Series page 1682), allowing us to write:

$$I = (kT)^3\zeta(3)\Gamma(3)\left(1-\frac{1}{2^2}\right) = \frac{3}{2}\zeta(3)(kT)^3 \qquad (12.5.359)$$

Therefore:

$$n_e = 2\frac{1}{c^3\hbar^3}\frac{3}{2}\zeta(3)(kT)^3 = \frac{3}{c^3\hbar^3}\zeta(3)(kT)^3 \cong 3\cdot 10^8 T^3 \qquad (12.5.360)$$

where $\zeta(3) \cong 1.2$ is the Riemann zeta function of 3. The mean free path is found after plug-in all numerical values to (remember that we take $T = 10^{10}$ [K]):

$$\lambda_\gamma = (n_e\sigma_T)^{-1} \cong (3\cdot 10^8 T^3\sigma_T)^{-1} \cong \left((3\cdot 10^{38})\cdot(6.652\cdot 10^{-29})\right)^{-1} \cong 5\cdot 10^{-11}\,[\text{m}] \qquad (12.5.361)$$

or about the size of a typical virus. So, yeah: tiny. The Universe is effectively opaque!

As the Universe continues to cool we eventually expect neutral hydrogen to form and the free charge-carrier density to decline rapidly in a process confusingly named "recombination" (there's nothing "re-" about it).Naively, we might expect this transition to occur as the universe cools through $T = 10^5$ [K], which corresponds dimensionally to the ionization energy of hydrogen, $E = 13.6$ [eV].

Indeed, if we consider that the first atoms absorbing photons and avoiding the transparency of the Universe were Hydrogen atoms. As electrons "orbiting" the hydrogen proton never had by assumption the time to "relax" (reached their fundamental state) because of the density of the early Universe we can assume that all absorbed photons were for electrons between the first and second main quantum number. But as we have proved in the section of Corpuscular Quantum Physics:

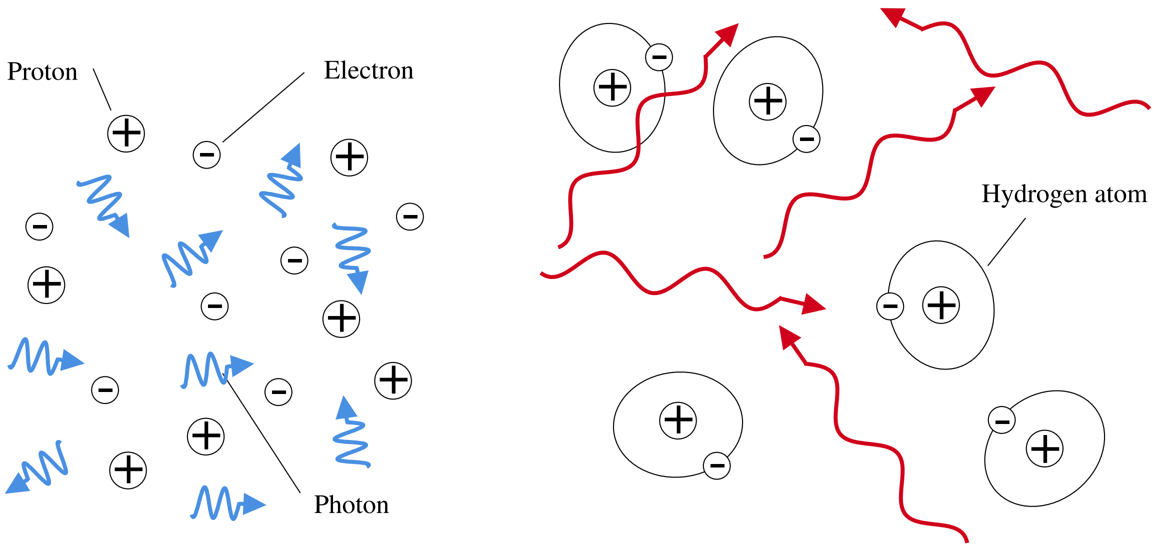
$$E = h\nu_{n_2,n_1} = Z^2\frac{me^4}{8\varepsilon_0 h^3}\left(\frac{1}{n_1^2}-\frac{1}{n_2^2}\right) \qquad (12.5.362)$$

and for Hydrogen:

$$E_{n_2,n_1} = h\nu_{n_2,n_1} = 13.605\left(\frac{1}{n_1^2}-\frac{1}{n_2^2}\right)\,[\text{eV}] \qquad (12.5.363)$$

So that's where the $13.605\,[\text{eV}]$ comes from!

At this energy the reaction $p + e^- \longleftrightarrow \text{H} + \gamma$ should begin to fall out of chemical equilibrium because background photons won't be able to re-ionize the newly formed hydrogen.



A. Before (re)combination B. After (re)combination

Figure 12.291: **Big Bang recombination**

With enough electrons locked away in hydrogen atoms, photons will propagate relatively unimpeded across the cosmos. This event, the corollary of recombination named "decoupling", is important because these are the very photons that make up today's cosmic microwave background. Let us see if this is indeed what happens by finding the photon mean free path when the Universe has cooled down below 13.6 [eV] to a tepid 1 [eV], corresponding to a temperature of roughly $T = 10^4$ [K] (around the temperature of a White Dwarf, or a really hot habanero). At these temperatures the electrons are no longer relativistic (since $T \ll m_e$) and so the number density assumes the classical Boltzmann (see section Electrokinetics page 4294) form:

$$\rho_C(E) = 2\left(\frac{m_e kT}{2\pi\hbar^2}\right)^{3/2} \exp\left(\frac{\mu - E_C}{kT}\right) \tag{12.5.364}$$

That we will rewrite here:

$$n_e = 2\left(\frac{m_e kT}{2\pi\hbar^2}\right)^{3/2} \exp\left(\frac{\mu_e - m_e c^2}{kT}\right) \tag{12.5.365}$$

Indeed, as photons do not interact with each other, hence they can not achieve a thermodynamic equilibrium by themselves, therefore their chemical potential is zero.

Again... the reader may often found this relation in natural units in some textbooks leading to:

$$n_e = 2\left(\frac{m_e T}{2\pi}\right)^{3/2} \exp\left(\frac{\mu_e - m_e}{T}\right) \tag{12.5.366}$$

However we can't solve n_e directly because we don't know $\mu_e(T)$ in general. So the idea is to use the Saha ionization equation (see section Continuum Mechanics page 3954):

$$\frac{x_e^2}{1 - x_e} \cong \frac{\eta}{n_\gamma} e^{-B/kT} \left(\frac{m_e m_p}{m_{\text{H}}}\right)^{3/2} \left(\frac{kT}{2\pi\hbar^2}\right)^{3/2} \tag{12.5.367}$$

where for recall $x_e = n_e/n_b$ is the ionization fraction, B the ionization of the first level of Hydrogen atom $B = 13.6$ [eV] and where we know (assuming equal charge density) that the photon to baryon ratio is given by $\eta = n_\gamma / n_b \cong 1.85 \cdot 10^9$ with $n_\gamma \cong 370 \cdot 10^6$ photons by cubic meter and $n_b \cong 0.2$ baryons by cubic meter.

So we found at $T = 10^4$ [K] after putting all numerical values in the previous relation :

$$\begin{aligned}\frac{(n_e/n_b)^2}{1-(n_e/n_b)} = \frac{(n_e/370\cdot 10^6)^2}{1-(n_e/370\cdot 10^6)} &\cong \frac{\eta}{n_\gamma} e^{-B/kT}\left(\frac{m_e m_p}{m_\mathrm{H}}\right)^{3/2}\left(\frac{kT}{2\pi\hbar^2}\right)^{3/2}\\ &= \frac{1.85\cdot 10^9}{2\cdot 10^{-7}} e^{-\frac{2.17896\cdot 10^{-18}}{k\cdot 10^4}}\left(\frac{m_e m_p}{m_\mathrm{H}}\right)^{3/2}\left(\frac{k\cdot 10^4}{2\pi\hbar^2}\right)^{3/2}\end{aligned} \tag{12.5.368}$$

and solving for n_e (keeping only the positive solution):

$$n_e \cong 370\,[\text{electrons}\cdot\text{cm}^{-3}] = 370\cdot 10^6\,[\text{electrons}\cdot\text{m}^{-3}] \tag{12.5.369}$$

The mean free path is found after plug-in all numerical values to $\lambda_\gamma = (n_e \sigma_T)^{-1} \cong 4.07 \cdot 10^{19}$ [m] or around $1,300$ parsecs. That's quite a distance - significantly longer than the mean free path during nucleosynthesis - but still only a sliver of the observable universe at that time. Hardly across all the cosmos. Apparently the universe is still quite ionized even at $E = 1$ [eV]. So what's going on?

For one, there are hugely many more photons than charge-carriers per unit volume. The hugeness of this disparity is the result of the tiny matter-antimatter asymmetry (CP-violation as seen page **??**) in the early universe: most of the matter and all of the antimatter annihilated to generate a glut of photons, leaving only a tiny residual matter density. All told, there are roughly 10 billion photons for every electron in the universe. With so many more photons than electrons, even at $T = 10^4$ [K] there were enough photons all they way out in the ultraviolet tail of the blackbody spectrum with energies greater than 13.6 [eV] to keep hydrogen relatively well-ionized. To find out just how many let us recall that he have seen during our derivation of the Planck's law (see section Thermodynamics page 3719), that:

$$\mathrm{d}n = \frac{\frac{V 8\pi\nu^2}{c^3}\mathrm{d}\nu}{e^{\frac{h\nu}{kT}}-1} \tag{12.5.370}$$

And therefore the photons cubic density in our case is given by:

$$n_\gamma := \int \frac{\mathrm{d}n}{V} = \int\limits_{13.6\,[\text{eV}]}^{+\infty} \frac{8\pi}{c^3}\frac{\nu^2\mathrm{d}\nu}{e^{\frac{h\nu}{kT}}-1} \tag{12.5.371}$$

By multiplying by h^3/h^3, we get:

$$n_\gamma = \int\limits_{13.6\,[\text{eV}]}^{+\infty} \frac{8\pi}{h^3c^3}\frac{(h^2\nu^2)\mathrm{d}(h\nu)}{e^{\frac{h\nu}{kT}}-1} = \int\limits_{13.6\,[\text{eV}]}^{+\infty} \frac{8\pi}{h^3c^3}\frac{E^2\mathrm{d}E}{e^{\frac{E}{kT}}-1} = \frac{1}{\hbar^3\pi^2c^3}\int\limits_{13.6\,[\text{eV}]}^{+\infty} \frac{E^2\mathrm{d}E}{e^{\frac{E}{kT}}-1} \tag{12.5.372}$$

Remark

In natural units the latter relation can be found in the following form in some textbooks:

$$n_\gamma=\frac{1}{\pi^2}\int\limits_{13.6\,[\text{eV}]}^{+\infty}\frac{E^2\mathrm{d}E}{\exp(E/T)-1}\tag{12.5.373}$$

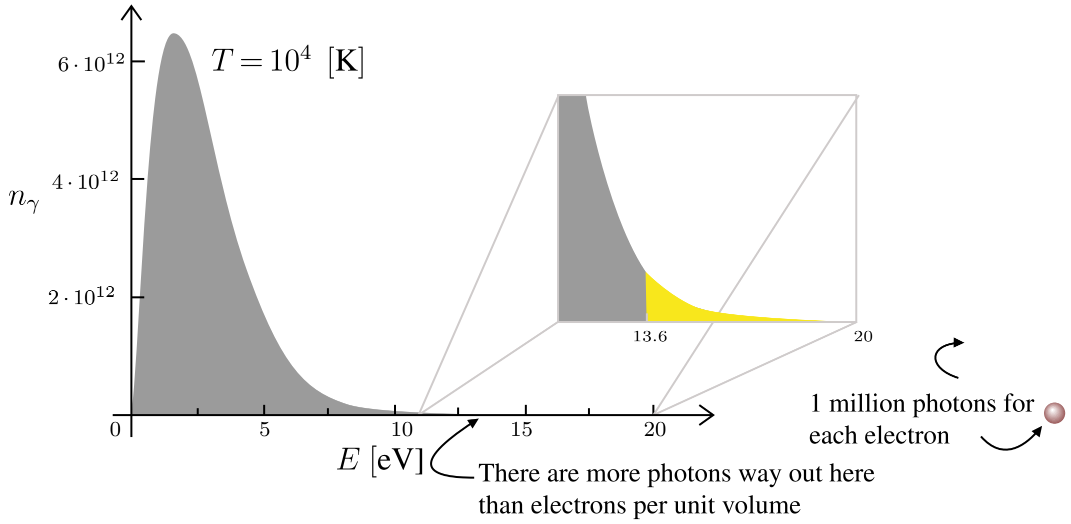
Sadly it seems that this definite integral has no analytical expression. So we will have to compute it numerically. As actual softwares can't deal with such small values (because 13.6 [eV] is equal to $2.17896\cdot 10^{-18}$ [J]) we will need to do a change of variable. We put $u=E/(kT)$ that leads us to:

$$n_\gamma=\frac{1}{\hbar^3\pi^2c^3}\int\limits_{13.6\,[\text{eV}]}^{+\infty}\frac{E^2\mathrm{d}E}{e^{\frac{E}{kT}}-1}=\frac{1}{\hbar^3\pi^2c^3}\int\limits_{15.78215}^{+\infty}\frac{u^2k^2T^2(kT\mathrm{d}u)}{e^u-1}=\frac{k^3T^3}{\hbar^3\pi^2c^3}\int\limits_{15.78215}^{+\infty}\frac{u^2\mathrm{d}u}{e^u-1}\tag{12.5.374}$$

In a mathematical computing software like Maple™, this gives us:

$$n_\gamma\cong\frac{k^3T^3}{\hbar^3\pi^2c^3}\cdot 0.3954884946\cdot 10^{-4}\cong 3.3\cdot 10^{14}\,[\text{photons}\cdot\text{m}^{-3}]\tag{12.5.375}$$

Result to compare with the $n_e\cong 370\cdot 10^6$ [electrons $\cdot\,\text{m}^{-3}$] (at the same temperature of $T=10^4$ [K]) determined above. Then there are around one millions photons with an energy greater than $E=13.6$ [eV] for every electron! This means that for every neutral hydrogen atom that forms, there are schools of high-energy photons available to re-ionize it.



1 million photons for each electron

There are more photons way out here than electrons per unit volume

So then when does recombination happen? To find out, we'll need to do a more careful accounting of the electron and baryon number densities. In particular, we're going to track the ionization fraction, $x_e=n_e/n_b$, where the baryon density includes the protons and neutral hydrogen, $n_b=n_p+n_\text{H}$. We assume that the electrons, baryons, and photons are all in thermal equilibrium, which is true so long as the reaction $p+e\rightleftharpoons \text{H}+\gamma$ proceeds rapidly relative to the expansion rate of the universe. In equilibrium, the chemical potentials balance $\mu_e+\mu_p=\mu_\text{H}$: this condition is our starting point. We know from our earlier results that we are well inside the non-relativistic regime when recombination finally does happen, so all equilibrium abundances have the Boltzmann form. Writing the condition $\mu_e+\mu_p=\mu_{\text{H}}$ in terms of n_e, n_p, and n_{H} gives as proved during our study of the Saha Equation (see section Continuum Mechanics page 3954):

$$\frac{x_e^2}{1-x_e}\cong\frac{\eta}{n_\gamma}e^{-B/kT}\left(\frac{m_e kT}{2\pi\hbar^2}\right)^{3/2} \tag{12.5.376}$$

with:

$$n_\gamma=\frac{1}{\hbar^3\pi^2c^3}\int\limits_0^{+\infty}\frac{E^2\mathrm{d}E}{e^{\frac{E}{kT}}-1}=\frac{k^3T^3}{\hbar^3\pi^2c^3}\int\limits_0^{+\infty}\frac{x^2\mathrm{d}x}{e^x-1} \tag{12.5.377}$$

The last integral can also be solved via geometric series expansion and some low-level tricks. The idea is again to use the binomial theorem for negative integer exponents (see section Calculus page 1707) involving the exponential:

$$I=\int\limits_0^{+\infty}e^{-x}(1-e^{-x})^{-1}x^2\mathrm{d}x=\int\limits_0^{+\infty}\left[\sum_{k=0}^{+\infty}(-1)^k(-1)^k e^{-(k+1)x}\right]x^2\mathrm{d}x=\int\limits_0^{+\infty}\left[\sum_{k=0}^{+\infty}(-1)^{2k}e^{-(k+1)x}\right]x^2\mathrm{d}x \tag{12.5.378}$$

After another change of variables, $y=(k+1)x$:

$$I=\sum_{k=0}^{+\infty}(-1)^{2k}\frac{1}{(k+1)^3}\int\limits_0^{+\infty}y^2e^{-y}\mathrm{d}y \tag{12.5.379}$$

The keen eye might recognize $\int\limits_0^{+\infty}y^2e^{-y}\mathrm{d}y$ as the gamma function (see section Differential and Integral Calculus page 1574), $\Gamma(3)=(3-1)!=2$. This, together with a slight nudge to the bottom limit of the summation we can rewrite things as:

$$I=\Gamma(3)\sum_{k=1}^{+\infty}\frac{(-1)^{2k}}{k^3} \tag{12.5.380}$$

Now notice that:

$$(-1)^{2k}=\left((-1)^2\right)^k=1 \tag{12.5.381}$$

Thus:

$$\sum_{k=1}^{+\infty}\frac{(-1)^{2k}}{k^3}=\sum_{k=1}^{+\infty}\frac{1}{k^3}=\zeta(3) \tag{12.5.382}$$

Therefore:

$$I=\Gamma(3)\sum_{k=1}^{+\infty}\frac{(-1)^{2k}}{k^3}=\Gamma(3)\zeta(3)=2\zeta(3)\cong 2.404 \tag{12.5.383}$$

So finally:

$$n_\gamma = \frac{k^3T^3}{\hbar^3\pi^2c^3}\int\limits_0^{+\infty}\frac{x^2\mathrm{d}x}{e^x-1} = \frac{k^3T^3}{\hbar^3\pi^2c^3}2\zeta(3) \cong 5.37\cdot 10^6 T^3 \tag{12.5.384}$$

Hence:

$$\begin{aligned}\frac{x_e^2}{1-x_e} &\cong \frac{\eta}{n_\gamma}e^{-B/kT}\left(\frac{m_em_p}{m_\mathrm{H}}\right)^{3/2}\left(\frac{kT}{2\pi\hbar^2}\right)^{3/2} = \frac{\eta\hbar^3\pi^2c^3}{2k^3T^3\zeta(3)}e^{-B/kT}\left(\frac{m_em_p}{m_\mathrm{H}}\right)^{3/2}\left(\frac{kT}{2\pi\hbar^2}\right)^{3/2}\\ &= \frac{\eta\pi^{1/2}c^3}{2^{5/2}k^{3/2}\zeta(3)}\left(\frac{m_em_p}{m_\mathrm{H}}\right)^{3/2}\frac{e^{-B/kT}}{T^{3/2}}\end{aligned} \tag{12.5.385}$$

Remark

The above relation can be found in natural units in some textbooks as following:

$$\frac{x_e^2}{1-x_e} \cong \frac{\eta\pi^{1/2}}{2^{5/2}\zeta(3)}\left(\frac{m_em_p}{m_\mathrm{H}}\right)^{3/2}\frac{e^{-B/T}}{T^{3/2}} \cong \frac{\eta}{4\zeta(3)}\sqrt{\frac{\pi}{2}}\left(\frac{m_e}{T}\right)^{3/2}e^{-B/T} \tag{12.5.386}$$

or inverted:

$$\frac{1-x_e}{x_e^2} \cong \frac{4\zeta(3)}{\eta}\sqrt{\frac{2}{\pi}}\left(\frac{m_e}{T}\right)^{-3/2}e^{B/T} \tag{12.5.387}$$

Knowing that the actual measured baryon to photon ratio is equal to $\eta \cong 1.85\cdot 10^9$, then for example at $T = 4,000$ [K] (≈ 0.33 [eV] a full two orders of magnitude below the hydrogen binding energy), we get:

$$\frac{x_e^2}{1-x_e} \cong \frac{\eta\pi^{1/2}c^3}{2^{5/2}k^{3/2}\zeta(3)}\left(\frac{m_em_p}{m_\mathrm{H}}\right)^{3/2}\frac{e^{-B/kT}}{T^{3/2}} \cong 6.37 \tag{12.5.388}$$

Therefore solving for x_e, this gives us: $x_e \cong 87.88\%$.

It may strike the reader as curious that recombination happens at all. Think about it: even without hordes of hot, ionizing photons flying around, a single recombination directly to the ground state releases a photon with an energy $E > 13.6$ [eV]. Unless the plasma density is sufficiently low (it isn't), these photons will readily re-ionize any neutral hydrogen atoms they happen upon. In fact, any recombination - even those to excited states of hydrogen - release photons capable of re-ionizing other neutral hydrogen atoms in the same excited state. Evidently, recombination must proceed via very particular transitions through the excited states of hydrogen; for example, the decay from $2s$ to $1s$ proceeds via the emission of two photons, neither of which has sufficient energy to excite hydrogen out of the ground state. The other pathway is through Lyman α decay (a 10.2 [eV] photon from $2p$ to $1s$): while absorption of a Lyman α photon will excite neutral hydrogen to a readily-ionizable state (a mere 3.5 [eV] away), as the hydrogen density decreases with the expansion the Lyman α photon redshifts just enough to render it harmless. These transitions work; the problem is that they are slow, and they get slower as the ionization fraction falls. Recall that thermal equilibrium is maintained when reactions proceed at a faster rate than the expansion. As recombination proceeds and the ionization fraction falls, these key transitions to the hydrogen ground state are too slow to maintain equilibrium and are therefore no longer adequately described by the Saha Equation. As a result, the Saha Equation predicts a more rapid recombination process than actually occurs through these slow, out-of-equilibrium decays. It is possible to do a proper job of this, taking into account out-of-equilibrium interactions involving the excited states of hydrogen. The Saha Equation is sufficient for our purposes! It illustrates the physics and gives an order of magnitude estimate of the temperature of recombination.

Putting this all together, we revisit the photon mean free path. With $n_e = x_e n_b = x_e n_\gamma / \eta$ giving:

$$\lambda_\gamma = \frac{\eta}{x_e n_\gamma \sigma_T} \tag{12.5.389}$$

We can observe the mean free path of the photon grow as the formation of neutral hydrogen really gets going in the below figure where λ_γ is the mean free path (solid line), x_e ionization fraction (dashed line), vs temperature:

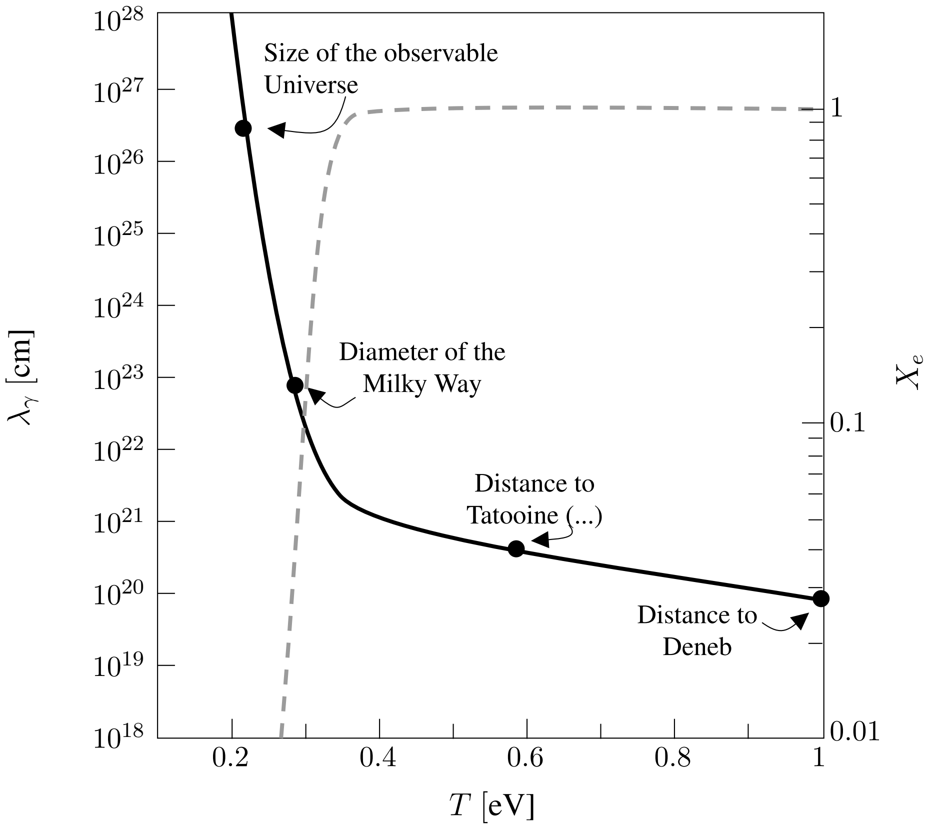


Figure 12.292: Ionization factor and mean free path in function of temperature

Photons traverse the whole of the visible universe unimpeded only when the ionization fraction has dropped below $x_e < 0.01$. These are the CMB photons. Only when the universe is mostly hydrogen (99 hydrogen atoms for every electron) does it become effectively transparent to photons. These photons, ladies and gentleman, are the cosmic background radiation: the CMB is born!

Obviously this result (as most results in this textbook) is just an approximation, but not a bad one. It's an approximation because it is a simplification of what is actually going on. In 11968 (holocene calendar), Jim Peebles (who had done the work in the 11965 Dicke etal. paper) and, independently, Yakov Zel'dovich (of the Sunyaev-Zel'dovich effect) in the USSR, worked out a more complete theory where the hydrogen has three energy levels, rather than what we have done here where we assume that the free electrons go straight into the ground-state (i.e. only two energy levels). Their third level was the $n=2$ state, the energy level just above the ground state. This is an important energy level for hydrogen, as it is transitions down to the $n=2$ level which give rise to visible-light photons. Using this more complicated 3-level model gives a Universe which is 90% neutral at a temperature of $T=3000$ [K], which is why this temperature is most often quoted.

12.5.5.3 Background radiation temperature

We have determined all lot of relations so far. Let us take now back the first Friedmann equation:

$$\left(\frac{\dot{a}}{a}\right)^2=\frac{8\pi G\rho}{3c^2}-\frac{k}{a^2} \tag{12.5.390}$$

and the Universe fluid equation:

$$\dot{\rho}=-3\left(\rho+\frac{P}{c^2}\right)\frac{\dot{R}}{R} \tag{12.5.391}$$

Now for flat space we have $k=0$ so the first Friedmann equation becomes:

$$\left(\frac{\dot{a}}{a}\right)^2=\frac{8\pi G\rho}{3c^2} \tag{12.5.392}$$

and as now we are interested by the radiation, we will not focus on mass density but rather on radiation (energy) density. Then that latter will be written:

$$\left(\frac{\dot{a}}{a}\right)^2=\frac{8\pi G\rho_{\text{E}}}{3} \tag{12.5.393}$$

But we have also proved during our study of the flat Universe dominated by radiation that:

$$\dot{\rho}_E+4\rho_E\frac{\dot{R}}{R}=0 \tag{12.5.394}$$

Then changing the notation and rearranging, we get:

$$\frac{\dot{\rho}_E}{\rho_E}=-4\frac{\dot{a}}{a} \tag{12.5.395}$$

Filling that latter relation inside:

$$\left(\frac{\dot{a}}{a}\right)^2=\frac{8\pi G\rho_{\text{E}}}{3} \tag{12.5.396}$$

gives immediately:

$$\frac{\dot{\rho}_E}{\rho_E}=-4\sqrt{\frac{8\pi G\rho_{\text{E}}}{3}} \tag{12.5.397}$$

We write $\dot{\rho}_E = \mathrm{d}\rho_E/\mathrm{d}t$ and integrate the previous relation (obviously such an integration is a non-sense but the idea is to have a first approach!):

$$\int \frac{\mathrm{d}\rho_E}{\rho_E^{3/2}} = -4\sqrt{\frac{8\pi G}{3}}\int \mathrm{d}t \tag{12.5.398}$$

This gives:

$$\frac{-2}{\sqrt{\rho_E}} = -4\sqrt{\frac{4\pi G}{3}}t \tag{12.5.399}$$

Now we square, and after rearranging we get:

$$\rho_E = \frac{3}{16\pi G t^2} \tag{12.5.400}$$

We also know the Stefan-Boltzmann law (see section Thermodynamics page 3706):

$$\rho(T) = \frac{4}{c}M(T) = \frac{8\pi^5 k_B^4}{15c^3h^3}T^4 \tag{12.5.401}$$

Therefore equating both relations:

$$\frac{3}{16\pi G t^2} = \frac{8\pi^5}{15c^3h^3}(k_B T)^4 \tag{12.5.402}$$

After rearranging we then have for a flat Universe dominated by radiation that the temperature is given by:

$$\boxed{T = \frac{1}{k_B}\sqrt[4]{\frac{45c^3h^3}{128\pi^6 G t^2}} \propto \frac{1}{\sqrt{z}}} \tag{12.5.403}$$

So when it comes to the observable age of the Universe $t_H \cong 13 \cdot 10^9$ [years], this will give:

$$T \cong \frac{1}{1.38065 \cdot 10^{-23}}\sqrt[4]{\frac{45 \cdot (299792458)^3\,(6.2607 \cdot 10^{-34})^3}{128 \cdot (3.1414926)^6 \cdot 6.67408 \cdot 10^{-11} \cdot (6.8328 \cdot 10^{15})^2}} \cong 0.01261\,[\mathrm{K}] \tag{12.5.404}$$

To compare with the 2.728 [K] observed today there is a huge difference. But whatever this gives us the information that the Universe should have a quite cold background radiation and experimentation confirms this!

Now according to Wien's second law we have (see section Thermodynamics page 3727):

$$\nu_{\max} = 2.82144\frac{kT}{h} \cong 0.7\,[\mathrm{GHz}] \tag{12.5.405}$$

To compare with the 282 [GHz] measured actually... So we are indeed in the range of the microwave. Hence the word "microwave" in the CMB...
